The degree of atrophy of the testes varied considerably. In some, the testes were reduced to an organ barely distinguishable from the vas deferens and in which no sign of spermatogenesis could be distinguished. In others the testes appeared normal in size and showed all stages of spermatogenesis up to what appeared to be normal, tailed spermatozoa. These, however, showed no sign of movement in physiological saline. All F_1 adults appeared normal in size and vigour and F_2 eggs were obtained from all but two of the crosses. These eggs were almost invariably sterile and microscopic examination showed no signs of embryonic development. Only on two occasions did a very few larvæ hatch, and these were from the reciprocal crosses between the Pare fresh-water form and the Tanga salt-water form.

An excess of males was always produced from crosses involving fresh-water form males and salt-water form females (both the Tanga strain and *A. melas*). This was most marked in the fresh-water form male × *melas* female cross. The two crosses between fresh-water form females and Tanga salt-water form males produced a slight excess of females in the F_1 generation. Similar crosses between fresh-water females and *melas* males gave a slight excess of males. The reciprocal crosses between the Tanga salt-water form and *A. melas* resulted in near-normal sex-ratios.

That some at least of the hybrid females were reproductively normal was shown by the production of viable offspring from back-crosses. These offspring all showed near-normal sex-ratios (Table 2). In addition to those back-crosses given in this table, the back-cross Tanga salt-water form male × hybrid Tanga male/Pare female was also successful, but no sex-ratio was recorded.

Table 2. BACK-CROSSES BETWEEN FRESH-WATER AND SALT-WATER FORMS OF *Anopheles gambiae*

Parents			F_1 generation	
Male	Female hybrid	Total	Percentage male	Percentage female
TSW	*melas* ♂/TSW ♀	184	47	53
melas	*melas* ♂/TSW ♀	20	45	55
Diggi	*melas* ♂/Diggi ♀	805	46	54
melas	*melas* ♂/Pare ♀	19	37	63
melas	Pare ♂/*melas* ♀	21	57	43

Footnotes of Table 1 apply here.

It would thus appear that *Anopheles gambiae* is a complex of at least four partially incompatible forms. Whether any or all of these deserve rank as separate species remains to be seen. If complete absence of gene-flow constitutes a criterion of specific rank, then these forms cannot be considered as separate species. A restricted flow is possible through back-crossing, at least in the artificial conditions of the laboratory.

Flour Mite, *Acarus siro* L., 1758, as a Species Complex

FOR more than forty years *Acarus siro* L., 1758, a pest of harvested cereals and cereal products, has been considered a very variable species consisting of several forms. Zachvatkin[1] concluded that these forms had no taxonomic significance since intermediate forms existed. Variation has been attributed both to the adult stage and to the hypopus stage (deutonymph), which sometimes occurs in the life-cycle, generally in response to certain unfavourable conditions. Schulze[2] described a motile migratory hypopus, capable of rapid movement but becoming passive once it has attached itself to another arthropod, and an inert form incapable of movement or attachment but resistant to desiccation. She ascribed both forms to *A. siro*, stating that both could be obtained from single pair matings.

A four-year study on hybridization, hypopus formation and the external morphology of populations of *A. siro* from stored products or outdoor habitats has shown there is involved a species complex made up of three species. Each species is capable of producing only one kind of hypopus, either motile or inert. After an extensive research into the literature, it is considered that the complex contains *A. siro* L., 1758; *A. farris*[3] and a new species.

When *siro* was crossed with the other two species only a small percentage of initial crosses succeeded. In these, gamete mortality occurred since each fertile pair yielded only a few offspring. F_1 hybrid sibling crosses did not produce offspring. Back-crosses to parent forms showed that F_1 females were sterile, whereas the majority of F_1 males were fertile. Initial crosses between *farris* and the third species were more successful; about 80 per cent of crosses produced some viable eggs. Both sexes of F_1 hybrids were fertile but only 25 per cent of F_2 and first back-cross eggs hatched. Fertility of F_2 sibling crosses was further reduced in that only 11 per cent of F_3 eggs hatched.

A. farris produces a motile hypopus and the new species an inert hypopus, quite frequently. Experiments revealed that these two hypopi differ physiologically, particularly in respect to resistance to desiccation. Also, an examination of the genetics of the hybrid hypopi has shown that polygenic inheritance occurs. A few out of many populations of *siro* have produced a motile hypopus which is morphologically different from that of *farris*. However, hypopus production in *siro* is rare.

Following examination of material collected from all over Britain and from parts of Europe, Canada, United States, Chile, Kenya and Egypt, it is concluded that the form designated here as *A. siro* L. is a stored product mite. Since the type no longer exists, arrangements are being made to erect a neotype. Oudemans's syntypes of *A. farris* have been examined and I select as lectotype the single male specimen bearing the following data. Left label (black ink in Oudemans's handwriting and crossed through twice in pencil): *Tyroglyphus farris* Oudemans ♂ type. Right label (black ink): in Kaas Arnhem 6. 2. 1902 Oudemans; below this is a small printed label stating: "Museum Leiden Verz. A.C. Oudemans collection Cat. No. 45". This species appears to occupy outdoor habitats.

A full account of this work is being prepared for publication elsewhere in which the new species will be fully described and named. Meanwhile, in view of the economic importance of this species complex, a simplified key for the separation of the adults is appended. It is based on chætotaxy of tarsus II of either sex, when the tarsus is viewed laterally. The nomenclature of the setæ follows Grandjean[4].

(1) Spine S at ventral apex of tarsus II large, about equal in length to tarsal claw; width of base equal to length of spines' shortest edge; tip of spine directed backwards. Solenidion omega$_1$, on dorsal basal third of tarsus, recumbent with a distinct 'goose-neck' preceding terminal 'head'. *A. siro* L.

Spine S fairly small, about half length of tarsal claw; width at base less than half the length of spines' shortest edge; tip not directed backwards. Omega$_1$ not recumbent, not 'goose-necked'. 2.

(2) Omega$_1$ with sides almost parallel; an indistinct 'neck' expands into a well-formed egg-shaped terminal 'head'. Widest part of 'head' exceeds widest part of stem. *Acarus* sp. n.

Omega$_1$ with sides diverging slightly from base, narrowing imperceptibly to an indistinct 'neck' then expanding slightly into terminal 'head'. Widest part of 'head' never wider than widest part of stem. *A. ferris* Ouds.

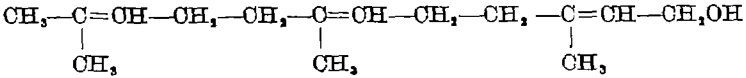
Juvenile Hormone Activity of Isomers of Farnesol

SINCE the juvenile hormone of insects was first extracted from the abdomens of male cecropia moths[1], its presence or the presence of juvenile hormone-like activity has been demonstrated in other insects[2], in invertebrates[3], in bacteria, yeast, and higher plants[4], in certain organs of mammals[5], and in the fæces of the beetle *Tenebrio molitor*[6]. Recently, the active constituents of the fæces of *T. molitor* were isolated and identified as two related acyclic sesquiterpenes, farnesol (I) and farnesal[7], and the activity of one of them, farnesol, was examined in detail on the assassin bug, *Rhodnius prolixus*[8]. Although the juvenile hormone activity of farnesol was demonstrated, its unit activity was far less than those of partially purified extracts of cecropia moths, and therefore it is not likely that farnesol is the true juvenile hormone of insects[8,9]. Nevertheless, interest is centred on these terpenes as possible precursors of the juvenile hormone.



$$\underset{\displaystyle CH_3}{CH_3{-}\underset{|}{C}}{=}CH{-}CH_2{-}CH_2{-}\underset{\underset{\displaystyle CH_3}{|}}{C}{=}CH{-}CH_2{-}CH_2{-}\underset{\underset{\displaystyle CH_3}{|}}{C}{=}CH{-}CH_2OH$$

(I)

We have also tested, and are able to confirm, the juvenile hormone activity of farnesol and farnesal and another related terpene, nerolidol, on *T. molitor* pupæ; no activity was found in geraniol, citronellol, squalene, and mevalonic acid lactone.

Table 1. JUVENILE HORMONE ACTIVITY OF ISOMERS OF FARNESOL

Concentration	*Trans, cis*	*Trans, trans*	*Cis, trans*	*Cis, cis*
77–129 μg/pupa	0	100	100	0
30–65 μg/pupa	0	100	100	0

The activity at two different concentrations is expressed as the percentage of *Tenebrio* adults showing pupal–adult intermediate genitalia. Ten pupæ were used for each isomer at each concentration.

There are four possible steric isomers of farnesol, the isomerism occurring at the Δ2 and Δ6 positions of the molecule. These four isomers were recently prepared in pure form[10] and we were able to obtain small amounts of them for testing. (We thank R. B. Bates, Department of Chemistry, University of Illinois, for supplying samples of the isomers of farnesol.) The assay used was the quantitative *Tenebrio* test[9], modified to the extent that concentrations injected into the pupæ were in micrograms and the results assessed by recording the presence or absence of pupal–adult intermediate genitalia in the adults. The isomers were dissolved in refined peanut oil and injected into 24–48-h-old pupæ of *T. molitor* at two ranges of concentration. The ranges of concentration were preliminarily determined to give 100 and 70 per cent adult–pupal intermediates, respectively, with commercially obtained farnesol.

In our tests, 100 per cent pupal–adult intermediates at both ranges of concentration were obtained with the *cis*-2, *trans*-6 and *trans*-2, *trans*-6 isomers of farnesol (Table 1). The results of the assay indicate that the biological activity of farnesol and related terpenes is resident in the *trans* configuration at the Δ6 or middle linkage, and further tests with homologues and analogues of farnesol are in progress.

MICROBIOLOGY

Effect of Various Bile Salts on the Anticandidal Activity of Amphotericin B and Gentian Violet and on the Anti staphylococcal Activity of Neomycin

A MIXTURE of bile salts contained in 'Bacto Bile Salts' (Difco) has been found capable of: (*a*) neutralizing the anti-candidal activity of a number of antimycotic agents including amphotericin B and gentian violet[1]; (*b*) potentiating the anti-staphylococcal activity of neomycin[2]; (*c*) effecting a mucin-like enhancement of intraperitoneal staphylococcal virulence for mice[3]. Considering the last, with the exception of sodium dehydrocholate, each salt contained in the bile salts mixture is capable of exerting this *in vivo* action[4]. Mucin, cholesterol and lecithin, which are present in unspecified amounts, also possess this same capability[5]. The work recorded here is concerned with the effectiveness of various bile salts as well as of mucin, cholesterol and lecithin on the first two *in vitro* activities already noted.

Sodium taurocholate, sodium glycocholate, sodium glycotaurocholate, sodium dehydrocholate, lecithin (animal) and cholesterol were obtained from Nutritional Biochemicals Corporation; sodium cholate from K. and K. Laboratories; sodium deoxycholate from Fisher Scientific Co. and gastric mucin from Wilson Laboratories. All were sterilized by autoclaving at 15 lb. for 15 min. Media were 1 per cent dextrose trypticase soy agar for *Candida albicans* and dilute trypticase soy agar containing 3 parts trypticase soy broth and 5 parts distilled water for *Staphylococcus aureus*. The former was adjusted to *p*H 6·8; the latter to 7·3. After melting and cooling to approximately 60° C, amphotericin B, gentian violet and neomycin were added as indicated to achieve a final concentration of 5·0, 10·0 and 0·1 μg/ml. medium, respectively, as well as varying concentrations of each substance under test. Each tube was well mixed mechanically and poured into a Petri dish. After cooling and solidification, 0·1 ml. of an 18-h culture at 37° C of *Candida albicans* or of *Staphylococcus aureus* in liquid medium, adjusted to an optical density of 0·1 and 0·05 respectively on a Lumetron colorimeter at 650 mμ, was spread evenly over the surface. Inoculated plates were incubated for 48 h at 37° C, and then observed for the presence or absence of distinct microbial growth. Growth control plates containing the various test substances alone without any antimicrobial agents were also prepared and tested for their possible growth inhibitory effect on both micro-organisms being investigated. None inhibited their growth in the maximum concentrations used. Neutralization of the antimycotic agents was evidenced by the production of definite candidal growth when a particular test substance was added to the medium as contrasted to complete lack of growth when it was omitted. 0·5 μg of neomycin/ml. medium was found to be the minimal inhibitory concentration for the standard *Staphylococcus aureus* inoculum and neomycin potentiation was indicated by the achievement of bacterial inhibition with only 0·1 μg/neomycin/ml. medium as a result of the addition of the particular test substance to the medium.

The minimal concentration per ml. of medium of each substance under investigation that neutralized the anticandidal action of 5 μg/ml. of amphotericin B and 10 μg/ml. of gentian violet and which effected a 5 times or greater enhancement of the anti-staphylococcal activity of neomycin is contained in Table 1.

As may be noted from Table 1, 15 mg/ml. or less of each bile salt elicited both effects under consideration, with one exception. 80 mg/ml. sodium dehydrocholate was required to inactivate the gentian violet

Table 1. Minimal concentration in mg/ml. of various bile salts and other test substances required to neutralize the anticandidal action of amphotericin B and gentian violet; and to effect a five times or greater potentiation of the anti-staphylococcal activity of neomycin

Substance	Neutralization 5 μg/ml amphotericin	Neutralization 10 μg/ml. gentian violet	Five times or greater potentiation of neomycin
Bile salts mixture ('Difco')	5·0	5·0	10·0
Sodium taurocholate	12·5	6·0	5·0
Sodium glycocholate	10·0	8·0	10·0
Sodium glycotaurocholate	10·0	10·0	15·0
Sodium cholate	15·0	6·0	1·0
Sodium deoxycholate	1·5	1·6	1·0
Sodium dehydrocholate	> 100·0	80·0	> 100·0
Gastric mucin	> 50·0	20·0	> 50·0
Animal lecithin	> 50·0	6·0	> 50·0
Cholesterol	1·0	50·0	> 50·0

whereas 100 mg/ml. of the same salt failed to neutralize amphotericin B or potentiate neomycin. As for the other substances investigated, 20 mg/ml. of gastric mucin was able to neutralize the anti-candidal activity of gentian violet but the maximum concentration employed with this substance, 50 mg/ml., had no such effect upon amphotericin B. Similarly, while lecithin, 6 mg/ml., neutralized gentian violet, 50 mg/ml. was ineffective against amphotericin B. As little as 1 mg/ml. cholesterol, on the other hand, did neutralize amphotericin B but 50 mg/ml. of the same compound was required to achieve the same effect with gentian violet. No potentiation of the anti-staphylococcal activity of neomycin was observed with the maximum concentration used of mucin, lecithin or cholesterol, 50 mg/ml.

It is noteworthy that every bile salt that proved effective in amphotericin B and gentian violet neutralization, neomycin potentiation and enhancement of intraperitoneal staphylococcal virulence for mice, is able to lower surface tension significantly as determined by the capillary tube method[6], whereas the one bile salt that was ineffective, sodium dehydrocholate, does not possess this property[4]. For this reason the existence of a possible relationship between the possession of this physical property by a substance and its ability to effect both the *in vitro* and *in vivo* effects under consideration is readily suggested. No explanation is forthcoming for the irregular action in this regard of mucin, lecithin and cholesterol, all which possess significant surface tension lowering ability[5].

CYTOLOGY

Isolation of Nuclei from Animal Cell Suspensions

IN a previous communication, a method for the quantitative isolation of nuclei from HeLa cells was described[1]. The nuclei were isolated by stirring the cells in a dilute solution of 'Tween 80' under controlled conditions. It seems worth reporting that the method has now been successfully applied to strain *L*, Chinese hamster, Ehrlich ascites and Krebs 2 ascites tumour cells. It appears likely that it will prove to be applicable to a wide range of animal cell suspensions.

GENETICS

Homeostasis and the F_1 Hybrid

IN his letter defining 'social homeostasis' Mackintosh[1] has referred to the uniformity of first crosses of inbred strains as compared with the parental stocks citing the monograph by Lerner[2] and the more recent review by Biggers, McLaren and Michie[3]. These authors are perhaps influenced by their genetic theories. The results of experiments performed by Dobzhansky and Wallace[4] justify their conclusions that "homeostatic adjustments are superior in heterozygotes to those in homozygotes". However, Lerner himself points out that most other experimental work cannot provide unequivocal evidence on the role of heterozygosity in developmental homeostasis as "even when the phenotypic $F1$ variance is lower than the parental average, the reduction may have been due to the genetic and not to the environmental component".

It is unwise to suppose that because results with a particular anæsthetic using two inbred strains and their reciprocal hybrids suggest superior development homeostasis of the heterozygotes all other first crosses will fall into line. In work with pentobarbitone sodium, Brown[5] showed that both F_1 crosses out of $DBA/1$ and $A2G$ strains resembled $DBA/1$ strain more nearly in the precision of their responses measured by λ. One of these hybrid strains $A2DB/1F_1$ gave a response to insulin (Brown[5]) well outside either of its parent strains and significantly less precise than its parent the $DBA/1$ strain. Further, the responses of the F_1 hybrid strains $A2CF_1$ and $CA2F_1$ each more closely resembled its maternal parent. These results may be compared with those noted by Chai[6] and by Grüneberg[7]. From the literature it would appear, therefore, that there is no general rule as to the response of inbred strains and F_1 crosses and for any particular experimental procedure the choice between inbred and F_1 animals can only be made after preliminary testing and observation.

ANNIE M. BROWN
MARJORIE DINSLEY

Laboratory Animals Centre,

[7] Grüneberg, H., *Lab. Anim. Centre Coll. Papers*, **3**, 29 (1955).

THE second paragraph in Brown and Dinsley's communication might be construed to refer to my communication on the effects of strain and group size on the response of mice to 'Seconal' anæsthesia. If this is indeed true, I would like to point out that I nowhere suggest that "because results with a particular anæsthetic using two inbred strains and their reciprocal hybrids suggest superior development homeostasis of the heterozygotes all other first crosses will fall into line". In fact, if Table 1 of that communication is referred to it can be seen that particular environmental conditions can result in equal amounts of variation being shown by both the heterozygote and the homozygote, for example, Part 2, two per cage, all strains, and Part 2, eight per cage *CE*/*CE*♂ × *CBA*♀ F_1.

Brown and Dinsley also refer to the work of Brown, who showed that the reciprocal hybrids of *DBA*/1 and *A2G* resemble the *DBA*/1 strain in the precision of their response as measured by λ, defined by her as the ratio, standard deviation : slope of regression.

This may be used as a measure of the accuracy of an assay but it is not, in a quantitative response, a measure of variation. In this connexion Chai is explicitly concerned with precision of assay rather than with variation and many of his data are concerned only with the sensitivity of the response. He also points out that to suggest that equivalent precision between hybrids and pure lines renders them equally suitable for bioassay may be to ignore other advantages which have been reported to accrue with hybrids.

PSYCHOLOGY

Relationship between Test Difficulty and the Visual Impairment in Monkeys with Ablations of Temporal Cortex

BILATERAL ablation of inferior temporal cortex gives rise to impairment of visual discrimination performance in monkeys. This visual impairment is not associated with a comparable tactile or auditory deficit. Nor is it a simple consequence of damage to the geniculo-striate visual afferent system. Such damage can often be excluded histologically; and direct comparison between the effects of temporal and striate ablations gave distinct patterns of impaired performance[1].

All conventional tasks suitable for testing the monkey's visual performance require the animal to learn to discriminate between two or more test objects. The animals with temporal ablations may be impaired at learning the solutions of visual problems (a defect of learning), or at discriminating by vision between the test objects (a defect of discrimination, perception or differentiation) or in some other way. In many studies the relative importance of learning and discrimination has been varied for a series of tasks, to establish the kind of test giving maximal impairment. No definitive conclusion has been reached as there are probably no pure tests of visual learning (without some discrimination) nor of discrimination (without some learning). A different approach is to analyse the nature of a certain class of tests (retention or relearning tests) and to examine the results relating to test difficulty for such tests.

The effects of inferior temporal ablations in monkeys may be assessed by examining discrimination performance either during post-operative (new) learning or during post-operative retention testing (re-learning): in post-operative learning the animals are trained to discriminate between test objects which have never previously been shown to them; with post-operative retention testing objects that had already been used pre-operatively are again made available, but after surgery. A general finding, applicable both to post-operative learning and retention, is that impairment is greater with increasing test difficulty. Thus "previous studies have shown that monkeys with lesions of both temporal lobes fail on 'difficult' and do better on 'easier' tasks"[2]. Tasks are graded as 'difficult' or 'easy' by reference to the learning scores of unoperated animals.

The relationship between impairment and test difficulty is readily understood for post-operative new learning. The operated animal's learning and/or discrimination capacities may be insufficiently taxed on the easy tests and its defects remain masked; on the difficult tests its capacities are more fully taxed and are shown to be impaired. In the same way a backward child may do as well as a clever child on an easy task but not on a difficult task. However, the greater impairment on difficult tasks during post-operative new learning does not indicate the nature of the defect (learning, discrimination or other).

In the case of post-operative retention testing animals are by convention trained before surgery to an identical standard level of performance (criterion) irrespective of task difficulty; so that, on a naive view, differences in test re-learning difficulty have been eliminated. The greater impairment on the more difficult tests has then not been attributed to a defect of (re-)learning capacity as this is thought, on the naive view, to be equally taxed on both easy and difficult retention tests.

However, training before surgery to a constant criterion involves proportionately more overtraining with easy tasks, proportionately less overtraining with difficult tasks. Overtraining improves retention in unoperated monkeys, and may eliminate impairment otherwise expected in operated animals[3]. The impairment on the difficult tasks during post-operative retention testing may then generally reflect the relative lack of overtraining on these tests. The relatively greater amount of pre-operative overtraining on the easy tests is likely to have eliminated a defect of learning, rather than of discrimination, associated with the temporal ablations.

This interpretation accords with the proposals of others that on easy discrimination tests "long criterional runs may provide sufficient overtraining to produce habits resistant to the operation"[3], and that certain ablations might be associated with "a permanent impairment in the ability to acquire discriminations"[4]. It is also in agreement with the conclusions of Mishkin and his colleagues[1,5] based on evidence unrelated to test difficulty. However, emphasis on factors related to a defect of discrimination, not of learning, has previously been placed by others[2,6].

Irrespective of the process, whether learning or discrimination, influenced by overtraining, it would be useful to examine the effect of temporal ablations on easy and difficult tasks learnt before surgery but with equivalent amounts of overtraining. A first attempt has been made to equate the overtraining for tasks of different difficulty by training unoperated animals to a directly proportional criterion[7]. Six unoperated animals were trained (before dietary treatments) on three tests of different difficulty to a proportional criterion: to a level of 90 per cent correct responses in 10 consecutive trials if the criterion performance began between trials 1–100; to 90 per cent correct in 20 trials if this criterion began to be met between trials 101–200; to 90 per cent correct in 30 trials if between trials 201–300; and so on. All animals were re-trained to a fixed criterion during retention testing (also before dietary treatments began). Differences in test difficulty which existed during learning were found on retention testing to have been reduced by the use of a directly proportional criterion during training. Such differences might have been eliminated by use during training of a criterion bearing a geometrical relationship to test difficulty.

STATISTICS

k-State Markov Chains

EXAMINATION of random sequences from Markov chains enables us to judge the relative efficiency of various methods which have been developed for testing different statistical hypotheses. A good deal of work, therefore, has been done recently by various authors[1-7] on the distribution of the number of transitions between adjoining observations of sequences from k-state Markov chains. The methods and results obtained in these investigations are rather unwieldy and cumbersome. The object of the present communication is to obtain the results for k-state chain from those of the two-state.

For a two-state chain defined by states a and b with the transition matrix (p_{ij}), i, $j = a$ or b, the probability that the r-th observation is in state a is given by:

$$P_r(a) = P_a + \{P(1 - P_a) - (1 - P)P_a\}\delta_{aa}^{r-1} \quad (1)$$

where P_a is the asymptotic probability of a for the chain, P the initial probability for the chain to commence with a and $\delta_{aa} = (p_{aa} - P_a)/(1 - P_a)$.

Assuming the initial observation to be a, that is, putting $P = 1$ in equation (1) reduces it to:

$$\begin{aligned} P_r(a/1a) &= P_a + (1 - P_a)\delta_{aa}^{r-1} \\ &= P_a + (p_{aa} - P_a)\delta_{aa}^{r-2} \quad (2) \end{aligned}$$

$Pr(a/1a)$ is the conditional probability for the r-th observation to be a when the first one is a. It can easily be seen that the conditional corresponding probability for the k-state chain is given by the same expression as equation (2), the values of P_a and p_{aa} being those for the k-state chain.

The conditional probability $P_r(a/1b)$ has been obtained from first principles for $r = 2,3 \ldots$ for the k-state and reduces to:

$$P_r(a/1b) = P_a + (p_{ba} - P_a)\delta_{aa}^{r-2} \quad (3)$$

Expression (3) is same as (2) with p_{aa}, the transitional probability of aa changed to p_{ba}, the transitional probability of ba.

Following this the conditional probability for the r-th observation to be in state l subject to the condition that the first observation is m is given by:

$$P_r(l/1m) = P_l + (p_{ml} - P_l)\,\delta_{ll}^{r-2} \quad (4)$$

where p_{ml} is the transitional probability for ml and:

$$\delta_{ll} = (p_{ll} - P_l)/(1 - P_l)$$

From the foregoing results using the properties of simple chains we can easily write down the probability of t-th, u-th and v-th observations of the sequence to be in states t, u and v as (asymptotic probability for t) (conditional probability of u when t-th observation is t) (conditional probability of v when u-th observation is u) which is equal to:

$$P_t\{P_u + (p_{tu} - P_u)\delta_{uu}^{u-t-1}\}\{P_v + (p_{uv} - P_v)\delta_{ll}^{v-u-1}\} \quad (5)$$

Using these results the cumulants for the various distributions arising from k-state Markov chain sequences can be obtained in a form much simpler than has been done so far. This is being worked out and the results will be published shortly.

MISCELLANEOUS

Rocket Engines

IN his review of my book *Rocket Engines*[1], Mr. J. E. P. Dunning takes me to task for stating that the change in total pressure of the burning gases consequent on heat addition in the combustion chamber is not a true loss. He writes, "When heat is added to a gas flowing in a duct it suffers a fundamental loss in total pressure *which cannot be recovered by subsequent cooling*" (my italics).

Mr. Dunning's statement is not strictly true, however, since the equations for heat addition to a flowing gas do not necessarily involve any irreversibility: a decrease in stagnation temperature should increase the stagnation pressure by just the same amount that an increase in temperature reduces it. This point has been clearly demonstrated by Shapiro, who followed the theoretical arguments[2] by actually building a machine in which evaporative cooling was used to increase the stagnation pressure of a flowing stream[3].

It is, of course, indisputable that in any practical rocket combustion system there are other pressure losses, due to friction, turbulence and so on, which are irreversible. But a large part of the stagnation pressure change is that due to heat addition, and my original statement that this is not a loss, since the original pressure could theoretically be restored by cooling, was quite justifiable.

May I add that I was otherwise much heartened by the generous tone of the review.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, December 3

University of London (in the New Engineering Building Lecture Theatre, University College, Torrington Place, London, W.C.1), at 5 p.m.—Prof. S. A. Schelkunoff (Columbia University): "Generalized Telegraphist's Equations and Their Applications".* (Further lectures on December 5 and 7).

British Society for the Philosophy of Science (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. J. H. Woodger: "Lopsidedness, its Cause and Cure".

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London W C.2), at 5.30 p.m.—Discussion on "Plugs, Sockets and Interconnexions" opened by Mr. N. E. Hyde,

Royal Institution, Library Circle (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Mr. J. S. Chapman: "English Explorers and Their Books".

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. G. C. Bunn, Mr. D. M Pilcher and Mr. T. W. Ball: "Reconstruction of Sewers for the Metropolitan Borough of Shoreditch".

British Society for International Health Education (at the Draper's Hall, Throgmorton Street, London, E.C.2), at 6 p.m.—Dr. Brock Chisholm: "New Horizons in Health".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—Mr. Jens Bjerre. "Rendumu" (Colour films with commentary).

Society of Chemical Industry, London Section (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. J. E. Davis: "Recent Developments in the Gas Industry".

Tuesday, December 4

Council for Microphotography and Document Reproduction (at the Connaught Rooms, Great Queen Street, London, W.C.2), at 1 p.m.—Sir Frank Francis: Presidential Address, followed by Mr. K. A. Fairthorne: "Microphotography and Information Retrieval—Implications of the Alliance".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. A. P. Goffe: "Active Immunization Against Measles".* (Fifteenth of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

Plastics Institute (at the Wellcome Building, Euston Road, London, N.W.1), at 6.30 p.m.—Mr. W. B. D. Brown: "A Different Way of Looking at Management".

Wednesday, December 5

Royal Society of Arts (at John Adam Street, London, W.C.2), at 2.30 p.m.—Dr. D. A. Sutton· "Modern Natural and Synthetic Glues and Adhesives".

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5 p.m.—Mr. J. A. Bather: "Control Charts and the Minimization of Costs".

Institute of Petroleum (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. I. J. Smith: "The Precision of IP Test Methods".

Institution of Electrical Engineers, Science and General Division P.G.S.7 (at Savoy Place, London, W C.2), at 5 30 p.m.—Discussion on "Character Recognition" opened by Mr. P. M. Hall.

British Institution of Radio Engineers, Radar Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Dr. J. W. R. Griffiths: "Signal/Noise Performance of Radar and Sonar Displays".

Institution of Mechanical Engineers, Steam Plant Group and Nuclear Energy Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. T. P. Webb and Mr. W. R. Wootton: "The Design and Construction of Heat Exchangers for Gas-cooled Nuclear Power Plant".

Society for Analytical Chemistry (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Meeting on "Applications of X-ray Fluorescence".

Wednesday, December 5—Friday, December 7

Royal Photographic Society of Great Britain (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2)—Symposium on "Quality in Photographic Reproduction".

Thursday, December 6

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. G. Pontecorvo, F.R.S.· "Microbial Genetics: Achievements and Prospects" (Leeuwenhoek Lecture).

Institute of Refrigeration (at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, Southwark Bridge Road, London, S.E.1), at 5.30 p m.—Mr. N. A. Tapsfield: "The Development of Two-Temperature Domestic Refrigerators".

Institution of Electrical Engineers (at Savoy Place, London. W.C.2), at 5.30 p.m.—Mr. R. H. Tizard: "Data Processing".

University College, London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. J. H. Gaddum, F.R.S. "Chemical Transmission in the Central Nervous System".*

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1) at 5.30 p.m.—Dr. H. J. Rogers· "Bacterial Cell Walls and Membranes".* (Sixteenth of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)

Radar and Electronics Association (at the Royal Commonwealth Society Hall, 18 Northumberland Avenue, London, W.C.2) at 7 p.m.—Prof. Sir Bernard Lovell, F R.S.: "Investigation of Space by Probes and Radio".

Royal Institute of Chemistry, London Section (at the Northampton College of Advanced Technology, St. John Street, London. E.C 1), at 7 p.m.—Dr. G. H. Williams "Some Aspects of the Chemistry of Free Radicals".

Oil and Colour Chemists' Association, London Section (at the Royal Society of Tropical Medicine and Hygiene, Manson House. 26 Portland Place, London, W.1), at 7 p.m.—Mr. J. S. Marsh "Colour Match Predictions using Organic Pigments".

Women's Engineering Society (at "Hope House", 45 Great Peter Street, London, S.W.1), at 7.30 p.m —Miss L. Chitty. "Some Aspects of Water Supply".

Friday, December 7

Institution of Electrical Engineers, Electronics Division P.G.E5 (joint meeting with the British Institution of Radio Engineers Medical Electronics Group, at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Masers and Lasers and the Possible Applications in Medicine and Biology".

Institution of Mechanical Engineers, Education and Training Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Overseas Training of British Graduates".

Society of Chemical Industry, Fine Chemicals Group (joint meeting with the London Section, at 14 Belgrave Square, London. S.W.1), at 6.30 p.m.—Dr. A. Olow: "The Chemical Industry before Muspratt".

Royal Institute of Chemistry, London Section (joint meeting with the East Anglia Section, at the Mid-Essex Technical College and School of Art, Market Road, Chelmsford, Essex), at 7 p.m.—Dr. I. G. Holden: "Science in the Detection of Crime".

Saturday, December 8

Association of Agriculture and the British Agricultural History Society (at the London School of Economics, Houghton Street, London, W.C.2), at 11 a.m.—Conference—"Agrarian History Some Vistas and Pitfalls (with special reference to Medieval England)".

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3 30 p.m.—Mr. Barrie Reynolds "Magic and Witchcraft Practices in Barotseland".*

Monday, December 10

Institution of Mechanical Engineers, Manipulative and Mechanical Handling Machinery Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Universal Excavators *versus* the Front End Loader".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Sir John Hunt, C.B.E., D.S.O.: "A British-Russian Expedition to the Pamirs".

Monday, December 10—Tuesday, December 11

Powder Metallurgy Joint Group of the Iron and Steel Institute and the Institute of Metals (at Church House, Great Smith Street, London, S.W.1), at 11.15 a.m. on Monday and 10 a.m. on Tuesday—Winter Meeting.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Junior Demonstrator (with a special interest in palæomagnetic research) in the Department of Physics—The Registrar and Secretary, King's College (University of Durham), Newcastle upon Tyne (December 7).

Research Officer (with sound postgraduate experience in pig or animal nutrition) in Pig Nutrition in the Department of Agriculture—The Registrar, University College of North Wales, Bangor, North Wales (December 7).

Assistant Lecturer, Grade B (graduate in chemistry, and preferably the ability to teach physics or an applied science), at Northampton College of Technology, to teach physical and organic chemistry to Higher National Certificate standard—Chief Education Officer, Northampton County Borough Education Committee, "Springfield", Cliftonville, Northampton (December 8).

Lecturer in Inorganic and Physical Chemistry; and a Lecturer in Mathematics—The Principal, Nottingham and District Technical College, Burton Street, Nottingham (December 8).

Lecturer in the Department of Physiology—The Secretary, The University, Aberdeen (December 10).

Lecturer in Pure Mathematics; a Lecturer in Applied Mathematics; an Assistant in Pure Mathematics; and an

ASSISTANT IN APPLIED MATHEMATICS at Queen's College, Dundee—The Secretary, University of St. Andrews, Queen's College, Dundee (December 14).

LECTURER or ASSISTANT LECTURER IN THE DEPARTMENT OF SOCIAL ANTHROPOLOGY—The Secretary, The University, Edinburgh (December 14).

LECTURER IN THE DEPARTMENT OF BOTANY at the University of Natal, Pietermaritzburg—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, December 15).

LECTURER or ASSISTANT LECTURER IN THE DEPARTMENT OF CHEMICAL ENGINEERING—The Deputy Registrar, The University, Birmingham 15 (December 15)

SENIOR LECTURER IN GEOGRAPHY; and a LECTURER IN GEOGRAPHY at the University of Auckland, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W 1 (New Zealand and London, December 18).

READER (with research interests which include non-numerical applications of computers) IN INFORMATION PROCESSING at the Computer Unit—The Academic Registrar, University of London, Senate House, London, W.C.1 (December 19).

LECTURER (with a good honours degree in chemistry or pharmacy or an equivalent qualification) IN PHARMACY—The Registrar, The University, Manchester 13 (December 20)

SENIOR LECTURER or LECTURER IN CHEMISTRY at the Royal College, Nairobi—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 30).

SENIOR LECTURER (with an honours or higher degree in physics, and preferably with previous teaching and research experience) IN THEORETICAL PHYSICS at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (December 31).

READER IN THEORETICAL NUCLEAR PHYSICS—The Clerk to the Governors, Battersea College of Technology, London, S.W.11 (January 15).

LECTURER IN THE DEPARTMENT OF THEORETICAL PHYSICS—The Registrar, The University, Liverpool, quoting Ref. No. CV/208 (February 1).

SENIOR LECTURER (with a degree in pure science and/or in agriculture, and preferably postgraduate experience in genetics) IN PLANT GENETICS—The Registrar, Lincoln College (University of Canterbury), Canterbury, New Zealand (February 1).

LECTURER (graduate in engineering or mathematics) IN ENGINEERING (Applied Mechanics or Electrical Engineering, or Thermodynamics)—The Registrar, The University, Leicester.

SENIOR LECTURER or LECTURER (preferably with an interest in numerical analysis) IN THE DEPARTMENT OF MATHEMATICS, University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

SENIOR SCIENTIFIC OFFICER and a SCIENTIFIC OFFICER (with at least a good honours degree in chemistry or equivalent) IN THE SCIENTIFIC BRANCH, for a wide variety of interesting work on research development and scientific control—The Medical Officer of Health (D.1/O/2706/11), L.C.C., County Hall, London, S.E.1.

THE DRUG INDUSTRY AND PUBLIC SAFETY IN BRITAIN

THE rise of the pharmaceutical industry cannot be dated with the same precision as that of the dyestuffs industry, but its development in the latter part of the nineteenth century was closely related to that of organic chemical industry and the wealth of organic intermediates which the growth of the dyestuffs industry made available. Nevertheless, the outbreak of the First World War found Great Britain almost entirely dependent on Germany for her supplies of synthetic organic pharmaceuticals, and the manufacture of such products in Britain is essentially a development of the inter-war years. At the outbreak of the Second World War in 1939, however, the pharmaceutical industry was entering on a new phase of rapid and continuous development as the outcome of a period of intensive scientific research which brought many new products to light and is well illustrated by the simple fact that 70 per cent of to-day's prescriptions could not have been written in 1935, and 45 per cent even five years ago because the drugs did not exist.

The coincidence of the discovery of the valuable but expensive drugs resulting from this research with the introduction of a free and comprehensive Health Service for all was largely responsible for the rise in the cost of prescriptions which led to the appointment in June 1957 of a Committee of Enquiry with Sir Henry Hinchliffe as chairman, though, as the Committee pointed out in its final Report in 1959, inflation, population changes and the introduction of prescription charges all played their part. In that report, however, the Committee could also add: "The community as a whole derives tremendous benefits from the pharmaceutical service, financially as well as in relief of suffering and saving of life. The use of drugs has made a valuable contribution in the treatment of tuberculosis and other infectious diseases and in mental practice, and has relieved the pressure on hospital accommodation. *The Minister should reconsider ways and means of publicising these facts in a telling manner*".

The Committee was concerned to note the totally inadequate publicity given to the remarkable saving in life, improvement in health, increase in efficiency and saving on extensive institutional treatment stemming from, among other things, the use of new drugs. Nor was it in any doubt as to the vital importance of ensuring the continuance of the fundamental research on which the discovery of new drugs depends. Indeed, it recommended specifically that firms should be encouraged to increase their research effort and that the conditions which may make such research profitable, such as patent rights, the publicizing of proprietary names and the price agreement with the Ministry of Health should be accepted.

In spite, however, of its recommendation that the Minister of Health should consider ways and means of publicizing the facts about the industry's research effort and the widespread benefits derived from the introduction of new drugs, little seems to have been done to improve the publicity position, and the discussion on the control of and testing of drugs at the recent Labour Party Conference is the latest illustration of the need for public understanding of a position for which scientists may themselves have to carry some responsibility. The wilder statements about profits were promptly repudiated in the Press by the Association of the British Pharmaceutical Industry; but it might be recalled when Sir Frank Heath and A. L. Hetherington published their survey of *Industrial Research and Development in the United Kingdom* in 1946, pharmaceutical research was not even mentioned, while the alarm aroused by thalidomide is to a considerable extent due to misunderstanding of the position. Nor is it less important that the true position should be widely appreciated because some firms which are not undertaking the risks of research may be making disproportionate profits. It is difficult, for example, to justify the wide variations in price for what purport to be identical preparations. It should be recognized, however, that a firm which waited until the period of patent protection for some highly successful product was ending, and then put a team of technologists to develop an efficient process, could find the manufacture highly profitable and be able to under-sell heavily the rival firm which had spent millions of pounds on the original research and the biological and chemical testing of the product. If the conditions are such as to deter any firms from undertaking the risks of original research, the introduction of new products will soon cease and with it also the opportunities which the less-venturesome have exploited.

The Hinchliffe Report devoted a separate chapter to the question of research within the British industry in which the position is very fairly set forth, though it can scarcely be said that the Government has shown any real appreciation of the position or its implications during the subsequent three years. While the industry has undertaken to do anything in its power to assist the Ministry of Health in the smooth and equitable operation of the revised Voluntary Price Regulation Scheme, the Association of the British Pharmaceutical Industry did not conceal its fear that export and research incentives built into the original scheme had been dangerously diminished. Although firms in Great Britain may, individually, spend from £100,000 to £1 million per annum on research, the Association of the British Pharmaceutical Industry estimated the total expenditure as no more than £5,257,025 in 1959 compared with a reported £7 million in Switzerland and £43 million in the United States. For 1960 the figures are £7·5 million in the United Kingdom and £77 million in the United States. This expenditure is, moreover, recurrent and a firm which is spending £1 million a year may do so for several years without discovering and developing an important new product. Indeed, the Hinchliffe Committee itself suggested that a firm did well if it made one major advance in ten or twenty years, and although less-notable discoveries are more frequent, even here many hundreds if not thousands of new chemical compounds may have to be synthesized and tested before a new drug is introduced for clinical use.

Even among scientists the position is not always understood clearly, and from the point of view of science itself it seems highly desirable that there should be more understanding of what is involved in the research effort of the industry, both in the discovery of a new product and in the testing which it receives before it is submitted for clinical trial. The discovery of new drugs is, of course, related to developments in other branches of medical science, and this is equally true of their testing, whether for toxicity or in clinical practice. It is our lack of knowledge of the biochemical interaction between drugs and living processes, and of the processes themselves, that is the chief obstacle in a field where progress at the best must be slow and difficult.

As the Hinchliffe Committee points out, fundamental pharmacological research is costly. There are as yet no completely satisfactory theories of the action of drugs to provide a sure basis for predicting the therapeutic effects of new chemical compounds. No organic chemist can write down the formula of a new drug and guarantee that it will be a cure for cancer, high blood pressure, schizophrenia or any other disease. In practice, pharmacological research is essentially a matter of trial and error with only very occasional success.

It is also a collaborative effort in which not only the organic chemist but also the biochemist, the physical chemist, the pharmacologist, the bacteriologist, the pathologist and possibly also the endocrinologist, mycologist, botanist and parasitologist, as well as the pharmacist and medical practitioner may all have their place. It is a matter of team work in which the quality of the scientists is the decisive factor and in which the fullest advantage is derived only after several years of working together. As a corollary, it follows that research expenditure must be planned several years ahead, and besides this recurrent expenditure, considerable capital expenditure on plant and buildings may be required.

Nor is it only a matter of the time and effort put into the unpredictable laboratory investigations. Placing a new drug on the market for general therapeutic use always involves a big risk, quite apart from the fact that the new product may oust another product of the same firm which was previously considered the best for a particular purpose. All the time this may happen as a result of the introduction of new products by another firm and there can be few industries in which it is possible for a market to be lost as quickly as in the pharmaceutical industry. Apart from this the successful products have to carry the costs of the unsuccessful products, including the lengthy investigations that may have ended in clinical trials.

The Hinchliffe Committee made no attempt to estimate the efficiency of the research effort of the pharmaceutical industry, nor, in the absence of a much more detailed inquiry, did it recommend any changes in the organization of the industry. It recognized that competition is inherent in the system of private enterprise and, where it functions freely, should lead to the discovery of more effective drugs, and that with established drugs competition must in fact reduce the price. It made, moreover, no suggestion for co-operative research, at least in respect of the fundamental research for new products, and although at the conference on the pattern of research in British industry organized by the Federation of British Industries, in April, Mr. Aubrey Jones challenged the practice of secrecy in the competitive system as wasteful of effort and as a possible disservice to the economy, it is worth recalling that, in January, Dr. J. Y. Bogue told the Pharmaceutical Society that in 43 years not a single worthwhile drug had been discovered by the State-run industry of the U.S.S.R., and that in Austria, State-controlled medicine had inhibited the growth of the pharmaceutical industry.

Where, however, co-operation should be possible is in the clinical trials, which are time-consuming and expensive in skilled manpower. The Hinchliffe Committee expressed the opinion that clinical trials of new drugs and preparations should be organized by the professional bodies who should also be asked to take responsibility for interpreting the results of the trials. It did not indeed suggest that those firms who arrange for such trials themselves should discontinue to do so; on the contrary, they should be encouraged to continue. The Committee's object in recommending that professional bodies should be asked to consider the whole question of clinical trials was rather to provide some authoritative review of all the clinical data.

It is this aspect that has been forced on public attention during the past year or so, and it is well that the public should be aware of the care and effort which the industry is giving to the evaluation of drug toxicity and the arrangement of clinical trials. Since the symposium on the evaluation of drug toxicity which marked the opening of the new research laboratories of the Pharmaceuticals Division of Imperial Chemical Industries, Ltd., there has been a succession of discussions on this theme and the transfer of drugs from the animal laboratory to man before the Royal Society of Medicine, the Pharmaceutical Society and elsewhere. It has been emphasized, moreover, that there is at the moment no prospect whatever of setting up even a remotely relevant screening test for detecting the sensitizing potential in new drugs.

The limitation derives from the nebulous nature of our knowledge of the factors involved in human hypersensitivity already mentioned, and the designing of satisfactory animal tests must await the accumulation of a sufficient body of knowledge about the human conditions which they are intended to model. This in turn is a matter of inter-disciplinary co-operation, but it has also to be remembered that though such collaboration can reduce it will never entirely eliminate the risk when clinical trials are first undertaken.

Sound judgment as the Committee, set up under Lord Cohen of Birkenhead in August, remarked in an interim report published on November 6, can ensure that such risks are not undertaken unless the potential benefits are worth while. In any event, the total risk has to be set against the immeasurable benefits which mankind has gained from the introduction of new means for controlling and treating disease.

In the report just mentioned, the Cohen Committee rejects the idea that the responsibility for testing drugs should in the first place be transferred to a central authority as neither desirable nor practicable. It recommends that the responsibility for experimental laboratory testing of new drugs before they are used in clinical trials should continue to rest on the individual pharmaceutical manufacturer. It was satisfied that the industry as a whole discharges this responsibility effectively within the limits of contemporary knowledge of methods of testing, and it added that this knowledge was constantly being extended by research and that the Medical Research Council is intending to give advice and guidance on this subject from time to time.

The Minister of Health announced, on November 6, that he accepted these recommendations but that he would await further advice before deciding to adopt the third recommendation, to appoint a new expert body to assess the evidence before new drugs are used in clinical trials. Other steps have also been taken recently to improve co-operation and eliminate waste of effort in this field. The Medical Research Council has appointed a Committee, with Sir Charles Harington as chairman, to advise and assist the Council in promoting research into experimental methods of testing drugs and their possible toxicity. Last September a European Society for the Study of Toxicity of Drugs was formed, membership of which is open to all scientists interested, whether employed in industry, universities, Government or international organizations. In a sense, too, the grant of £250,000 which the Distillers Co., Ltd., recently made available to the University of Edinburgh for research into the incidence and causes of congenital abnormality illustrates the widespread implications of pharmacological research. The 1,500 graduate and 3,000 other workers employed in research and development in the industry itself draw also on the work of many others in biology, chemistry, medicine and other sciences in the universities and elsewhere.

It must not be forgotten that if, as the Hinchliffe Committee considered, the cost of clinical trials should be borne by the pharmaceutical manufacturers, this in turn must be reflected in the price of drugs. At the ninety-ninth British Pharmaceutical Conference last September, Mr. J. Hanbury, in his chairman's address, said that since the effects of thalidomide in unborn children were made known, British manufacturers were submitting many of the drugs they had produced during the past ten years to fresh tests to determine their effects on the fœtus. These tests would add several million pounds to the annual cost of research and increase the demand for scientific manpower, but, while Mr. Hanbury once again emphasized that even so complete safety could not be ensured, it seems necessary to stress not only the need for and extent of scientific collaboration in all such developments but also that all this research and development has to be financed.

At present it is only done out of the rewards which accrue from the relatively few successful discoveries, and here, as was pointed out at a scientific meeting of the Pharmaceutical Society last January, the Minister of Health has chosen to ignore or reject the conclusions of the Hinchliffe Committee. His action in invoking Section 46 of the Patents Act may do immense harm to the British industry at home and overseas. His offer to purchase drugs from foreign countries removes the incentive to research, the only result of which in the long run is an ultimate reduction in the research effort and in the number of new drugs available for the home and overseas markets. Payment of a royalty to the true owner of the patent, as offered by the Minister, is manifestly inadequate in view of the published experience of the National Research Development Corporation and the magnitude of the research expenditure of the industry already indicated.

This unrealistic attitude of the Government is as disturbing as the widespread public ignorance of what is involved in the discovery and testing and manufacture of a new drug, which leads both to ill-informed criticism and needless alarm when some mishap occurs in clinical trials. It is a prime responsibility of that wide range of scientists whose work contributes to the continuous emergence of new drugs to do all in their power to dispel such ignorance, as well as to bring about a more realistic approach to the question by the Government. Nor is it less important that the opportunities which the industry affords for satisfying and creative work to the scientist himself should be duly appreciated by those taking up a scientific career. Indeed, fascinating as is the actual search for new drugs in itself, the work which goes into their trials up to, and including, their first use in clinical practice is no less rewarding and responsible. In the end the decision to recommend the release of a new product for trial on human patients is a matter of personal and professional judgment which demands all that the pathologist, the biologist or the medical practitioner can bring to bear. The industry carries no heavier responsibility than to see that those responsible for such judgments are of the highest possible professional competence; any Government whose policy hinders the maintenance of the highest standards here betrays its duty.

AGRICULTURE, FISHERIES AND FOOD

The Ministry of Agriculture, Fisheries and Food

By Sir John Winnifrith. (The New Whitehall Series No. 11.) Pp. 271. (London: George Allen and Unwin, Ltd.; New York: Oxford University Press, Inc., 1962.) 30*s*.

THIS book is primarily meant for those interested in public administration However, agriculture, fisheries and food attract attention from practically every branch of science, and mostly over the full range from fundamental research to simple applications to practice. Hence, readers of *Nature* will have special interest in the sections describing the scientific and technical activities, and the associated administrative procedures.

The book follows the general plan of the Series. The bulk of the text deals with the work of the Ministry; there are a compressed historical introduction and a concluding section describing the organization of headquarters, regional and local centres.

The story begins in 1793, when Sir John Sinclair and Arthur Young persuaded the Government to form an embryonic Board, which was passing rich on £3,000 a year, until they retired in 1820, when first the grant, and later the Board, lapsed. Then followed fifty years of leisurely Government tinkering with problems like land tenure and cattle diseases, until 1889, when the Board of Agriculture was formed It took over Fisheries from the Board of Trade in 1903, but parted with all its Scottish responsibilities to a newly formed Board there, in 1911. After the First World War the Board became a Ministry, through the curious procedural means of a private member's amendment to a Bill concerned mainly with other matters.

From 1930 onwards the work rapidly expanded: measures to cope with the slump in agricultural prices; import duties and quotas; marketing boards. The Second World War saw the immediate formation of a Ministry of Food, equipped with production plans, based on the experiences of 1914–18 and the inter-war years. The two Ministries achieved a remarkable and vital increase in home food production, both during and after the War The present net output is 60 per cent above pre-war. Methods have been revolutionized: the high degree of mechanization on the land and in farm buildings is now common knowledge, but the fact that two-thirds of the calves born in England and Wales are conceived through artificial insemination may be less widely known.

Ultimately the future of the Ministry of Food had to be decided. The possibilities were abolition, continuation, dispersion into existing Government departments, or complete absorption into the Ministry of Agriculture and Fisheries. The last of these was adopted after 'keen controversy'. Thus, the present-day Ministry, with its new unwieldy title, has grown from the £3,000 Sinclair–Young baby to a £278 million adult, and there is also a separately financed Scottish relative. But, of this large sum, nine-tenths is paid out in price guarantees, production grants and other subsidies.

A very summarized account is given of the sequence from 1910, when the Development Commission first made research grants under advice from the (then) Board of Agriculture, to the effectively independent present-day Agricultural Research Council, which dispenses yearly about £6,500,000 for fundamental research, mainly in the agriculture and veterinary sciences. Fishery research is still under the Ministry, and basic food research is mostly the concern of the Department of Scientific and Industrial Research, and various research associations. The Ministry now confines its attention to applied research, and the consequential control and advisory measures. It runs a number of laboratories, and a comprehensive National Agricultural Advisory Service. covering arable and animal husbandry. On the control side, special mention should be made of foot-and-mouth disease. The brief radio and Press announcements of an outbreak give no conception of the swift and intricate actions to contain it and to trace the precise origin of each fresh one. The account is aptly likened to thriller fiction and a Sherlock Holmes story—and, it happens to be true.

Sir John Winnifrith, in his preface, pays tribute to his colleagues' efforts in assembling the data. He has been well briefed, but the information has obviously been sifted and assembled through one mind. The result is a very readable and informative book, with occasional neat touches of humour to please the attentive reader. B. A. KEEN

PLANT SURVIVAL THROUGH THE RUSSIAN WINTER

Wintering of Plants

By I. M. Vasil'yev. Translated from the Russian by Royer and Roger, Inc. Editor of English translation: Jacob Levitt. Pp. xiv + 300. (Washington, D.C.: American Institute of Biological Sciences, 1961.) 9 dollars.

IN a country the size of the U.S.S.R., where even in the warmest latitudes temperatures may drop below −4° C, great importance is attached to research on wintering of plants. Unfortunately it has always been difficult for Western scientists to obtain more than a fragmentary record of this work since there has been no review of the subject translated into English. The American Institute of Biological Science has now provided such a review, originally published in the U.S.S.R. in 1956, which it has made the first of a series of translations of major Russian works in biology. The book aims to be of practical value, so it should have a wide appeal to those interested in either pure or applied botany.

The injurious effects and the causes of death due to cold, including chilling injury to half-hardy plants, are considered first. Apart from the inherent hardiness of the plants, the importance of good agronomic practice, both in land preparation and in subsequent husbandry, is emphasized. Snow is of major importance as an insulator from extremes of cold. As it is of limited value in protecting trees, various other methods of protection are described, ranging from the ingenious to the drastic.

The second and largest part of the book is devoted to the physiological aspects of wintering, and in it Vasil'yev describes many of his own experiments. The ability of a cell to survive at low temperatures rests on the adaptability of its protoplasm to the increasing cold at the onset of winter. The active changes involved in the protoplasm give it properties similar to those in young cells, and so hardening is considered to be in some ways comparable with rejuvenescence.

The vernalization requirement of winter cereals is discussed only in so far as it is associated with a growth form which has far greater survival in cold weather than the spring form. No mention is made of the bulk vernalization of grain prior to planting which was advocated by Lysenko, but has apparently never been used extensively in the U.S.S.R.

In the final part of the book breeding for winter hardiness is described using the principles evolved by Michurin. The normal methods of hybridization and selection are used, but the Russians also 'shatter' heredity by exposing plants to different environments and afterwards 'fix' heredity by 'training', which includes grafting to acquire permanently the desirable characteristics of the stock.

The book is clearly written, but the reproduction of the text figures is poor and there is no index. The text includes references to some three hundred original papers and the bibliography covers more than a thousand altogether. Two-thirds of these are by Russian authors, but since they have contributed more than anyone else to world knowledge on this subject this is to be expected, and the book remains a review of major importance in this otherwise rather neglected field.

R. G. Hurd

PROTEIN BIOSYNTHESIS

Protein Biosynthesis

A Symposium held at Wassenaar, 29 August–2 September, 1960, under the auspices of Unesco and the Council for International Organizations of Medical Sciences. Edited by R. J. C. Harris. Pp. xii + 409. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1961.) 95*s*.

THIS volume contains a collection of papers which were given at a conference held in The Netherlands in 1960. The discussions which followed the presentation of papers are also included. The twenty-seven original papers are accompanied by an introductory paper and concluding remarks given by Siekevitz and Chantrenne, respectively. Both these participants aimed in their thoughtful contributions at placing the subject of protein biosynthesis in a broad perspective; this redresses the balance of the book as a whole, which is affected by the inevitably specialized nature of many of the papers. The mechanism of protein biosynthesis in animals, plants and micro-organisms is considered. Many of the papers deal with the synthesis of proteins by various subcellular components. Most attention is paid to protein synthesis associated with ribosomes or microsome material. For example, McQuillen gives an account of the comprehensive studies carried out at the Carnegie Institution on the involvement of ribosomes in protein synthesis in *Escherichia coli*. Butler *et al.* describe work on *Bacillus megaterium* and consider the possible involvement in synthesis of amino-acids associated with lipid. The structure of ribosomes is considered in a number of papers as is the significance to be attached to the association of proteins such as ribonuclease or γ-globulin with ribosomes. There are also contributions on protein synthesis associated with other subcellular structures, such as mitochondria (Work *et al.*), myofibrils (Winnick and Winnick) and nuclei (in particular, Allfrey and Mirsky). An appreciable number of papers presents information on the role of 'soluble' or 'transfer' ribonucleic acid in protein synthesis, and some are concerned with its characterization. Several articles deal with anomalous nucleotides. Škoda gives an extensive list of such compounds and their biological properties. Gros and Naono describe the effect of fluorouracil on protein synthesis, and a brief mention is made of the concept of 'messenger' ribonucleic acid, which has received much attention since the conference in question was held. Many of the papers deal with general aspects of protein biosynthesis, but a number include consideration of more specialized aspects, such as the synthesis of serum albumin (Campbell), synthesis of globulins by plasma cell tumours (Askonas) and the effects of carcinogens on the function and fine structure of liver cells (Emmelot and Benedetti).

The general standard of the papers is high. Furthermore, the reader is supplied with a summary of most of the papers, the titles are given of most of the papers cited and there is an author index.

Despite the general excellence of the volume, the question does arise as to what useful purpose it can serve at the present time. There have been considerable advances in knowledge concerning the biosynthesis of proteins during the past two years, in particular, with respect to the parts played by the nucleic acids. The volume reviewed, therefore, cannot give an adequate overall picture of present knowledge. I consider, however, that it still retains some value for those who are actively concerned in this field of study.

J. L. Simkin

ANTIBIOTICS

Antimicrobial Agents Annual, 1960

Proceedings of the Conference on Antimicrobial Agents held in Washington, D.C., October 26–28, 1960. Edited by Peter Gray, Benjamin Tabenkin and S. G. Bradley. Pp. xviii + 670. (Washington, D.C.: Society for Industrial Microbiology, 1961. Distributed by Plenum Press, New York; and Heywood and Co., Ltd., London.) 8.50 dollars; 80*s*.

THIS volume containing some ninety papers submitted at the conference held in Washington at the end of October 1960 also records discussions of the papers and details of panel discussions on modes of action, clinical laboratory testing and on clinical problems. The wide coverage is indicated by the section headings: new products, laboratory studies, modes of action, clinical studies, antitumour agents, agricultural and non-medical uses. Inevitably there is some overlap of interests in these sections and it would be well for anyone interested in a particular section to scrutinize the titles in the others. On the whole, however, the editors have carried out a difficult task well.

Of the panel discussion, that on modes of action is less well documented than the others, is rather difficult to follow and leaves the impression that little advance has been reported. The papers and the discussion on clinical laboratory testing should be of interest to both clinicians and laboratory staff. It is clear from the discussion that a great deal of work remains to be done to bring some measure of standardization at national and international levels, and that too little attention is paid to size of inoculum in relation to the amount of antibiotics in sensitivity disks. There are some critical remarks about using disks as a quantitative measure of activity.

Several new antibiotics are described: 'Porfiromycin' (4 papers), 'Mikomycin' (2 papers) and the semi-synthetic penicillins (3 papers) appear to be the more interesting. Work on 'Porfiromycin' is given in detail but toxicity figures are lacking, an omission remarked on in the discussion; that on 'Mikomycin' gives a wealth of clinical results without much detail. The enzymatic cleavage and resynthesis of penicillins, some laboratory work on 'Methicillin' and on lower alkyl and haloalkyl penicillins will be of interest to workers in this field. Two papers deal with 'Cephalosporin *N*' and two with a new sulphonamide containing the isoxazolyl grouping.

In the clinical section of nineteen papers, five deal with the new penicillins, including the early American work on 'Methicillin', three with certain aspects of the use of 'Demethylchlortetracycline', the others with such matters as the action of antibiotics in the gastrointestinal tract, the clinical use of 'Vancomycin' and the treatment of such infections as Friedlander's pneumonia, pneumococcal and H. influenza type *B* meningitis, and ocular toxoplasmosis. The panel discussion is given over very largely to the treatment of the resistant staphylococcus.

The great interest in the antifungal agents is shown by some twelve papers on this subject and the need for more work is stressed.

Of the non-medical uses of antibiotics, the use of 'Tylosin' in chickens and turkeys to control infections in broilers and a paper summarizing non-medical uses of antibiotics in Great Britain with special reference to animal feeds, food preservatives and plant disease control are of interest.

This book will be necessary for most reference libraries, but its price will probably restrict its purchase by many individuals. JOHN FARQUHARSON

ANALYTICAL CHEMISTRY

Comprehensive Analytical Chemistry

Edited by Prof. Cecil L. Wilson and David W. Wilson. Vol. 1*C*: Classical Analysis: Gravimetric and Titrimetric Determination of the Elements. Pp. xxx + 728. (Amsterdam and London: Elsevier Publishing Company, 1962.) 140*s*.

THE publication of this book, part *C* of the first volume of *Comprehensive Analytical Chemistry*, has been awaited with considerable interest. Parts *A* and *B* have described the general techniques of classical analysis, and in this present book their application to individual chemical elements is further detailed. Previous parts of this series have attained a high standard of excellence, and if this present book is not quite of the quality of its precursors it is mainly because no single volume can possibly cover the wide range of problems associated with the classical analysis of the chemical elements.

The plan of this book is rational; each element is treated separately and a periodic system of classification is adopted which permits easy access to material. No space has been found in this present work for systematic schemes of analysis which form an integral part of classical gravimetric analysis, but it is to be hoped that this omission is to be remedied in a future volume.

The editors' intention of providing a working manual as well as a reference work has been met in many sections by some excellent and authoritative contributions. Their authors describe, giving full practical instructions, all stages of a chemical analysis from the pre-treatment and solution of the starting materials to the separation of the interfering elements, leading to the consequent determination of an element by a preferred method. This treatment is supplemented by ample references to the literature. However, not all contributors have adopted such a useful approach and give us instead a general treatment, in the main confining their attention to the actual chemical determinations, which are often only a small part of an analyst's task.

As befits a book of this type, the binding is stout, and the typography clear; this should be an important addition to an analyst's bookshelf. A. D. WILSON

REVIEW OF INFECTIOUS DISEASES

Natural History of Infectious Diseases

By Sir MacFarlane Burnet. Pp. x + 377. (Cambridge, The University Press, 1962, third edition.) 30*s*.

IT is a pleasure to review this, the third edition, of such a well-known work, which now presents an up-to-date account of the ramifications of an important subject, and as such it is welcome to doctors of medicine as well as to students of applied biology alike.

Throughout it adopts a Darwinian attitude, often overstepping the realms of human pathology into all kinds of unexpected avenues, as the result of wide knowledge and extensive reading. In its ambit it presents a picture of the ravages by bacteria, protozoa and viruses. Much of the information under the last-named heading is culled from the author's own original investigations. The philosophical considerations, as regards the origins of these viruses and their relationship to abstruse biochemistry, and even to the creation of life itself, are unique in their clear and delicious presentation. The processes of defence against disease are somewhat gingerly handled. because what was once considered as a simple explanation has now become an involved, intricate and contentious affair till we find ourselves in a globulin-infested land guided by the light of paper electrophoresis. Under mass prophylaxis, on which subject the author uses wise words, he discredits the practical value of antityphoid inoculation and would rather attribute the favourable results obtained to military sanitation.

As an introduction to the study of the zoonoses the student could do worse than read the condensed account of what is pure tropical medicine. Moreover, the reader will find here important information about such diverse subjects as myxomatosis in rabbits, the common cold, plague, German measles, poliomyelitis, the sweating sickness of the Middle Ages and Q. fever (from personal experience). The latter part of the book deals in detail with some important infectious diseases.

An epilogue on new diseases and the rather bleak outlook for the future finds the author in a gloomy mood in an appraisal of bacteriological warfare: but he is more optimistic about the eradication of tuberculosis, which he believes will be complete in due season.

The only criticism which can be offered is on a certain amount of repetition, which is possibly unavoidable in a book of this nature.

PHILIP MANSON-BAHR

THIRD INTERNATIONAL CONFERENCE ON PRECISION ELECTROMAGNETIC MEASUREMENTS

By W. D. GEORGE

National Bureau of Standards, Boulder, Colorado

THE third International Conference on Precision Electromagnetic Measurements was held during August 14–17 at the Boulder Laboratories of the National Bureau of Standards, Boulder, Colorado. Sponsored by the Radio Standards Laboratory of the National Bureau of Standards, the Professional Group on Instrumentation, Institute of Radio Engineers and the Instrumentation Division, American Institute of Electrical Engineers, the conference was concerned with the advancement of standards and accurate measurement throughout the coherent frequency spectrum. Fifty-five papers were presented in 10 sessions. There were technical discussions during an informal evening session, and the work of the Radio Standards Laboratory was demonstrated.

Dr. Frederick W. Brown, director of the Boulder Laboratories, welcomed some 560 members from Australia, Belgium, Canada, England, France, Japan, New Zealand, Sweden, Switzerland and the United States, and gave background information on the activities of the National Bureau of Standards. Dr. John M. Richardson, chief of the Radio Standards Laboratory and chairman of the Conference, spoke on the Conference's organization and objectives, pointing out that the subject-matter of high-level precision and accuracy throughout the entire coherent frequency spectrum involves the national standards laboratories of the world and other laboratories and organizations in contact with them. Also, a closer relationship between the standards laboratories and those who are making the discoveries which lead to improved accuracy and precision in measurement seems to be required.

The technical programme, under the chairmanship of Dr. George Birnbaum (Atomics International), included papers about, and related to, accurate measurement in determining: (1) low-frequency electrical quantities; (2) high-frequency and microwave quantities; (3) properties of materials; (4) applications of quantum electronics to precision measurement, for example, frequency, time and the velocity of light; (5) use of statistics as an aid to measurement; (6) the precision measurement needs of space technology. About 20 per cent of the papers were from outside the United States.

Dr. Robert D. Huntoon, deputy director, National Bureau of Standards, set the theme of the Conference as co-operation in focusing on precision electromagnetic measurements at all coherent frequencies and in pushing for improvement in the state of the art. In his address, he told of how the Conference work is related to the mission of national standards laboratories, and of the need for very close collaboration between scientists and laboratories in keeping on a common basis as closely as possible in standards, and in keeping on a common basis in precision terminology. It seems that each time a new measurement idea comes about it is duplicated, improved and incorporated in a standard which is returned for calibration. The problem is to keep the standards laboratories ahead of measurement requirements.

Session I: Space Electronics

The sessions commenced with five papers on space electronics, relating to space explorations, and in keeping with the world-wide emphasis now placed on this subject. The chairman, Prof. Samuel Silver, University of California, referred to the objectives previously given, namely, a reporting of the precision measurement problems in space.

W. E. Brown, jun. (Jet Propulsion Laboratory), dealt with "Measurement Problems of Space Vehicle Experiments". He pointed out that the need for conducting remote measurements by use of experimental sensors on space-vehicles, in an environment where there is often a large uncertainty in the parameter to be measured, establishes a new area of endeavour for the research worker. The conditions peculiar to this problem are in many instances vastly different from those normally encountered in laboratory research, and are related to the over-all spacecraft design requirements. These new conditions attach a new significance to calibration philosophy, sampling-rates, conversion accuracies and reliability. Furthermore, the ground data handling problem of extracting information from the large quantities of data is extremely severe and usually requires careful planning by the experimenters several months prior to the actual measurement. The paper surveyed the present and future aspects of acquiring accurate and intelligible information from the spacecraft sensors by the utilization of techniques which tend to be more compatible with the spacecraft design requirements.

D. B. Holdridge (Jet Propulsion Laboratory) described the computations and "Error Sources in the Determination of the Astronomical Unit from Venus Radar Observations". Radar reflexions from Venus when it was near the 1961 inferior conjunction were detected using continuous-wave techniques (2,388 Mc/s) in the Doppler and time-of-flight data systems. The data were compared with theoretical values obtainable by use of the available planetary position–velocity ephemerides and yielded a value of 149,498,845 ± 250 km for the astronomical unit (A.U.), or a solar parallax of 8″.7,940,976 ± 147 based on an Earth radius of 6,378,145 m.

Computations of the A.U. were made separately from the 'Newcomb ephemerides' and the 'Duncombe-corrected ephemerides'. Reduction of the Doppler data disclosed a small residual error in the difference between the heliocentric longitudes of the Earth and Venus in Duncombe's corrections to Newcomb's theory.

D. D. McKibbin (Lockheed Missiles and Space Co.) reported results from an ion chamber carried on about 100 orbits through the $F2$ region of the ionosphere. The measurements were made from 73° N. to 73° S. over altitudes of about 210–510 km. Kinetic ion temperatures were found to be 1,500° K and higher. Ion concentrations varied from 5×10^3 to 10^6 particles/cm^3. Fluctuations in the ion chamber values, especially in the southern auroral zone, indicated the presence of large ionization irregularities.

T. J. Crowther (Lockheed Missiles and Space Co.) gave a paper on "Automatic Range Switching of Instrumentation in Space Vehicles for Increased Accuracy". He described a device for making accurate measurements of electronic signals from a space-vehicle using automatic range switching. The device controls an instrument which has many operating ranges or scales and automatically selects the proper scale. The readings are then telemetered back to Earth on two channels, one to indicate which scale is in operation and the second to give the actual reading within the scale. Results from an actual application were given where accuracies of 5–15 per cent were obtained over a dynamic range of 10^4.

E. M. Bollin (Jet Propulsion Laboratory) discussed "Lunar Surface and Sub-surface Magnetic Susceptibility Instrumentation". His paper is a description of the development and the changes necessary in the instrumentation and transducer configuration to adapt a standard field method of magnetic susceptibility measurement to the special restrictions of space-craft electronics, transmission systems, measurement environment, and the restrictions imposed by sample geometry and size.

One of the major considerations is to get accurate information to the scientific community concerning the specific need for these rather specialized measurements. Accurate instrumentation was not previously developed as there was no specific need and no easy way of overcoming difficulties inherent in the measurement.

Session II: Direct Current and Low-Frequency Measurements

Five papers in this basic area of precision electromagnetic measurements were presented under the chairmanship of Chester Peterson (National Bureau of Standards).

G. A. Candela and R. E. Mundy (both at the National Bureau of Standards) described the measurement of "Absolute Magnetic Susceptibilities by the Gouy and the Thorpe–Senftle Methods". Dr. Candela pointed out that most magnetic susceptibility measurements in the past were made by relative methods. These depend on knowing the susceptibility of a reference substance; however, there are very few substances the susceptibility of which is known to better than about 1 per cent. To-day the measurements can be made easily and on an absolute basis on small samples. This results largely from the developments described and from measuring magnetic fields with a proton resonance magnetometer. It was suggested that laboratories equipped with the Gouy and Faraday apparatus should use the absolute measurement methods.

J. J. Hill (National Physical Laboratory, Great Britain) spoke on "The Design and Performance of High Precision Audio Frequency Current Transformers". The principal factor governing the performance of current transformers at high audio-frequencies is the magnitude of the product value of total leakage inductance and total interwinding capacitance. When the equations governing these quantities are examined it is found that there is an optimum thickness for the insulation space between the primary and secondary windings. Further improvement is obtained if the winding resistances, leakage inductances, and capacitances are all symmetrically and uniformly distributed. It is suggested that these conditions can best and most easily be realized by the use of single layer primary and secondary windings on a toroidal core.

The National Physical Laboratory has constructed transformers on this design to measure currents up to 400 amperes in the frequency band 400 c/s to 20 kc/s. The maximum ratio error at any load throughout this frequency-range is 17 parts in 10^6 and the maximum phase error is 50 μradians.

The discussion brought out the need for international agreement on how transformers are tested and the manner in which errors are to be specified.

P. L. Richman (Rotek Instrument Corporation) described "A New Peak to d.-c. Comparator for Audio Frequencies", an adjustment-free transfer technique for making precision comparisons between audio-frequency a.c. voltages and a reference d.c. Limitations and errors were estimated at 50 parts in 10^6 for the worst case in the over-all a.-c.–d.-c. transfer. Experimental verification for many of the error estimates was described, and experimental over-all comparison against thermal calibration and against a modification of the Smith–Clothier calibration technique was given. Agreement in the latter case was of the order of 30 parts in 10^6, indicating good correspondence with calculated error predictions. The comparator was usefully employed at frequencies up to 100 kc/s.

Dr. William A. Geyger (U.S. Naval Ordnance Laboratory) discussed "Low-Power-Operated d.-c. Instrument Transformers". Recent research work has been conducted toward the development of low-power-operated direct-current types of instrument transformers. The term, "d.-c. instrument transformer", has gained acceptance as a general name for those types of saturable-core devices which permit the measurement of direct currents and low-frequency currents, with a high degree of accuracy, without the use of power-consuming shunt resistors.

Dr. Geyger's paper describes a miniaturized d.-c. instrument transformer which is 60 c/s-operated from a correspondingly miniaturized switching-transistor magnetic-core multivibrator. In a special application to the measurement of currents derived from solar batteries, this low-power-operated d.-c. instrument transformer (the power drain on the 6-V battery is about 5 mW) eliminates the considerable power dissipation (up to 5 W) in a 5-ohm shunt resistor carrying the direct current to be measured. The device is also quite valuable for other applications, where small size, light weight, and an extremely low-power drain are of prime importance.

R. P. McKnight (Sandia Corporation) discussed the development and performance of "A Direct Reading Voltage Divider with Standard Cell Reference", in which the output voltage is equal to that of a standard cell when the input resistance has been adjusted so that 1 m.amp of current is flowing through the divider. The range of measurement with direct reference to a standard cell is 2–1,100 V. The range may be lowered to 0·02 V with decreased accuracy by the use of a Lindeck potentiometer in place of the standard cell. Results indicate that accuracies of approximately 0·005 per cent may be obtained from 2 V to 1,100 V without applying corrections.

Session III : Data Reduction in Precision Measurements

This session of four papers was mainly devoted to professional advice on the statistical analysis of data.

The first paper, "Uncertainties in Calibration", by W. J. Youden (National Bureau of Standards), also chairman of the Session, presented striking examples of research values which were improperly given in the literature. He spoke of incorrect simplifying assumptions, for example, treating systematic errors as though they were random. He then described efficient methods of clearly revealing systematic errors. General rules were given: we must improve the meaningfulness of limits set on measurement results, we need to know more about our random and systematic errors, we need to recognize that in many cases the available knowledge to form an estimate of errors is not reliable information, we must not jump the elementary steps, and we must be sure of what the precision errors are.

A. G. McNish (National Bureau of Standards), with a paper entitled "The Speed of Light", complemented the foregoing remarks. He summarized the present state of our knowledge regarding this important physical constant, and in doing so explained methods and techniques of analysis applicable to practically all well-controlled experiments. The concluding value after analysis of the numerous independent or semi-independent measurements was given as 299,792.50 ± 0·10 km/s.

The discussion brought out that there is no evidence either theoretical or experimental that the speed of light changes with frequency or with epoch.

The third paper, "Automatic d.-c. Data Logging System", was given by William Arnett (COHU Electronics, Inc.). He described a system which digitizes d.-c. voltages and records the values on punched cards for subsequent machine data reduction. The system has high precision, a few parts in 10^6, which is new in this field. Statistical analysis of the calibration data and information on stable voltage sources show the probable error to be about one part in 10^6. The speed of measurement, about 100 points in 6 min, and automatic self-calibration are also unusual with this type of system.

The last paper of this session, "Variance of Radio Frequency Caused by Atmospheric Turbulence in Line-of-Sight Transmissions", by K. A. Norton, E. C. Barrows, M. C. Thompson, jun., and H. B. Janes (all at the National Bureau of Standards), was given by Mr. Janes. This paper deals with the errors contributed by the turbulent lower atmosphere to standard radio frequencies transmitted over line-of-sight paths. Some measurements of these errors are discussed in terms of their effect on frequency and time-interval estimation. They are also compared quantitatively with the error contributed by transmitting oscillator instability.

The paper establishes the fact that, at the present state of the art, transmission of standard frequencies over a line-of-sight propagation path through the troposphere will not appreciably further deteriorate their accuracy relative to that available before this transmission.

Session IV : Properties of Materials

Recent developments in solid-state electronics and the increasing need for compact, light electronic devices with minimum power consumption for service in space-craft have focused scientific interest on the electromagnetic properties of materials. The examination of such properties requires the development of precise and convenient methods of measurement such as those explored by this conference. Prof. A. A. Oliner (Polytechnic Institute of Brooklyn) served as chairman and introduced the speakers.

Prof. L. M. Silber (Polytechnic Institute of Brooklyn) began the session with a paper prepared in co-operation with Prof. H. J. Juretschke (also of that Institute): "DC Effects Accompanying Ferromagnetic Resonance in Thin Films". The technique described permits the simultaneous measurement of several properties of a thin film: electrical conductivity, extraordinary Hall coefficient, magneto resistance anisotropy, permeability tensor and gyromagnetic ratio. Since all these properties can now be measured for a single film, their relationships can now be studied without the uncertainties of earlier methods which required the preparation of several identical films.

The second paper, "Microwave Faraday Rotation Using a Bimodal Cavity", by Dr. D. P. Snowden (General Atomic, San Diego, California), described the use of a TE_{111} bimodal cavity which is 1,000 times as sensitive as the direct method for measuring microwave Faraday rotation. Dr. Snowden pointed out that the same cavity can be used to measure the conductivity tensor or the susceptibility tensor of a material. During the discussion, Mr. H. E. Bussey (National Bureau of Standards) indicated that a bimodal TM_{110} cavity can be used in a similar way to measure the susceptibility tensor of a material with the added advantage that an exact mathematical analysis of the TM_{110} measurement is available.

Mr. A. D. Krall (U.S. Naval Ordnance Laboratory, Silver Spring, Maryland) spoke on "The Microwave Measurement of Narrow Line Width Ferromagnets by Radiated Fields". Mr. Krall showed that by placing a pick-up loop in the field radiated from a resonant sample the ferromagnetic line-width can be measured quickly, conveniently and with simple equipment. For narrow line-widths this method gives an accuracy of ± 0·02 œrsted. The first order anisotropy coefficient of the material can also be measured by this technique.

The final paper of session four was, "Measurement and Standardization of Dielectric Samples", by Mr. H. E. Bussey and Mr. J. E. Gray (both at the National Bureau of Standards, Boulder Laboratories). The introduction indicated that the art of measuring dielectric properties at microwave frequencies is maturing as is evidenced by the close agreement of different methods of measurement. Consequently, it now seems appropriate for the National Bureau of Standards to issue standard dielectric samples with specified dielectric constant and loss tangent. Mr. Bussey explained that accurate microwave dielectric constant measurements are made by correcting for the effects of all deviations from the ideal or perfect resonator or line. When this is done accuracies of 0·3 per cent for dielectric constant measurements and 5 per cent for loss tangent measurements become possible.

On August 13, the day preceding the Conference, an important meeting was held on high-temperature dielectric measurements. Attendance included representatives of about ten laboratories active in the field. Present-day methods were examined. A sample standardized to about 1,500° C is desired. To partially satisfy this need a round-robin comparison among interested parties will be conducted immediately.

Session V: Quantum Electronics in Precision Measurements

Seven advanced papers, under the chairmanship of Dr. R. C. Mockler (National Bureau of Standards), treated present and future possibilities of quantum electronics in precision measurements.

N. Bloembergen (Harvard University) discussed the new phenomena of non-linear optics which has become accessible to experiment by the advent of optical masers. The coherent nature of these new sources of light makes possible extremely high electro-magnetic fields within crystals which in turn reveal the non-linear behaviour of the medium. Maxwell's equations have been applied to this situation to obtain new laws of reflexion and refraction. The result is a theoretical basis for optical mixing, harmonic generation, and modulation with high intensity light beams.

A. Javan (Massachusetts Institute of Technology) presented evidence that the continuous-wave gas maser may achieve high reproducibility with the improvement of the mechanical resonator. He cited 3–4 sec stability of 1 part in 10^{13} and a reproducibility of 1 part in 10^{9} at present with a helium neon laser.

A. L. Bloom (Spectra Physics, Inc.) explained the use of optically pumped rubidium vapour as a precision magnetometer. This device is better known as a precision frequency source for atomic clocks. The sensitivity of the rubidium transition to magnetic field allowed a magnetometer to be constructed with a sensitivity of 10^{-8} gauss and a dynamic range of 10^{5}. Fast response and absolute accuracy were also claimed for the instrument.

J. P. Gordon (Bell Telephone Laboratories, Inc.) outlined the limitations of information-rate in communication channels due to quantum noise effects. The optimum signal should have the same statistical form as the noise. The differences between an amplitude sensitive receiver and a power sensitive receiver were explained. Each had advantages in some situations.

A. Ganssen (National Co., Inc.) discussed the advantages of a proton resonance oscillator in which the working substance could be water. This has advantages of room temperature operation and low-frequencies from -2 kc/s to 100 Mc/s. The disadvantage is the external magnetic field of high stability required. High spectral purity has been obtained along with stability of a few parts in 10^{10}.

Y. Beers and G. Strine (National Bureau of Standards) explained the use of the microwave Stark effect to measure high voltages to great precision. The instrument which was constructed consisted of a parallel plate microwave resonator of the Fabry–Perot type in which the Stark splitting of a molecular transition could be accurately measured. If the dipole moment of the molecule is known, the voltage across the parallel plates can be calculated with great accuracy. The instrument can also serve to determine the dipole moment if the voltage is known.

R. C. Mockler (National Bureau of Standards) outlined a proposed experiment to measure the velocity of light (γ-rays) using the Mossbauer effect. The source and detector are vibrated at high frequency in synchronism and the distance between them is varied to observe maxima in γ-ray absorption. This is a very difficult experiment but a measurement to a few parts in 10^{8} is expected to be possible.

Session VI: Atomic Frequency and Time (Hydrogen, Hydrogen Cyanide, Other Molecules)

This session with four papers and Dr. John T. Henderson (National Research Council) as chairman commenced the third day of the conference, a full day allotted to frequency and time.

A report on theoretical and physical properties of "The Atomic Hydrogen Maser", N. F. Ramsey and H. E. Peterson (Harvard University), was presented by Prof. Ramsey. He discussed effects of cavity pulling, wall coating of the hydrogen container within the cavity, magnetic fields, etc., which leads to shifts in the maser output frequency. From measurements made within the past week, the frequency difference between two independently constructed and independently adjusted machines was about 1 part in 10^{12}. A better agreement can be expected. In answer to inquiries he reported that instability in the electronic measuring apparatus (phase comparator) appears to be well under control, and is no longer a significant factor in evaluating the overall instability. The technique of looking at several nearby field-dependent transitions was described as the means of measuring the magnetic field actually seen by the atom in the maser itself.

The hyperfine frequency of atomic hydrogen, previously published as 1, 420, 405, 762. 415 ± 4·000 c/s (with reference to an atomichron), appears now to be known to about ± 0·030 c/s. Prof. Ramsey anticipates a hard push in obtaining a value known to 1 part in 10^{13}; however, he is confident that such can be obtained.

R. F. C. Vessot and H. E. Peters (Bomac Laboratories, Inc.) summarized their work on "Design and Performance of an Atomic Hydrogen Maser". Two objectives were mentioned: (1) design of a compact unit; (2) fundamental investigations on maser theory and performance.

Dr. Vessot reported details on one completely sealed off hydrogen maser, using 'vac ion' pumps, which has operated more than two months and is expected to operate two or more years. It may be likened to a tube with a large capacity getter and could be designed for 20 years performance. With no special precautions, beyond an air-conditioned laboratory, the instability relative to a second hydrogen maser was about six parts in 10^{13} in 1 min and five parts in 10^{12} in 10 h. It was pointed out that as the work progresses a fundamental importance will be given to measurement of the ratios of frequency of masers and other devices operating with different atoms such as cæsium, hydrogen and rubidium.

Dr. D. Marcus (Bell Telephone Laboratories, Inc.) described his "Hydrogen Cyanide Molecular Beam-Type Maser". It is a close relative to the ammonia maser, the first maser ever operated successfully. However, it differs from the ammonia maser in two important points. (1) It uses a different transition. While the ammonia maser uses the inversion of the nitrogen atom perpendicular to the plane defined by the three hydrogen atoms, the hydrogen cyanide maser uses the rotational motion of the molecule as a whole. This is the first successfully operated maser using a rotational transition. (2) The frequency of operation of the hydrogen cyanide maser is more than three times as high as that of the ammonia maser. This maser oscillates at 88·63 Gc/s corresponding to a wave-length in vacuum of 3·4 mm.

The design of this maser is interesting in that it used a great number of molecular beams which emerge from a circular source and converge on the resonant cavity which is located at the centre of the circle. A system of electrically charged rods arranged in two planes below and above the molecular beams removes the lower state molecules from the beams, thus achieving population inversion.

The resonant cavity is of the confocal interferometer type which is at present used in many optical masers.

This maser can be used as a precision frequency standard in much the same way as the ammonia maser.

A study of the possibilities of an electric resonance molecular beam frequency standard, "Choice of a Molecule for a Beam Frequency Standard", was presented by Dr. F. S. Barnes (University of Colorado). The devices described are analogous to the cæsium beam machines except that they operate with electric fields and electric dipole moments instead of magnetic fields and magnetic dipole moments.

Such devices might give nearly exact reproducibility except for: (1) uncertainty in field measurements in the *C*-field region; (2) uncertainties due to residual magnetic fields and a small magnetic dipole moment of many of the molecules which may be chosen; (3) measurement errors inherent in all beam type devices resulting from the finite '*Q*' and electrical noise; (4) shifts in the resonance from nearby molecular transitions; (5) unequal phase in the two cavities required.

Three kinds of detectors were investigated: hot wire, electron bombardment devices, and the Pirani gauge using semiconductive films.

The various sources of instability are hard to evaluate and a device should be built and operated to be sure. A stability of one part in 10^{13} can be expected.

Session VII : Atomic Frequency and Time (Ammonia)

Dr. Henderson continued as chairman and introduced a series of three papers which showed that precision and accuracy are still being improved for ammonia masers. In a paper "Ammonia Masers", K. Shimoda (University of Tokyo) discussed the effects of cavity pulling, longitudinal and transverse Doppler effects, the pressure shift, the dispersion of nearby lines, the effect of unresolved hyperfine structure, and the effects of magnetic field.

Also from Tokyo, Y. Saburi presented a paper "Characteristics of the 3–2 Line Maser of $^{14}NH_3$ and the Precision of Frequency Comparison", by Y. Saburi, M. Kobayashi, and Y. Yasuda (Ministry of Posts and Telecommunication). They considered the effects of changes in experimental parameters such as ammonia pressure, focuser voltage and magnetic field, as well as possible fluctuations from the associated quartz oscillator and frequency multipliers.

The third paper, "$^{15}NH_3$ Double Beam Masers as a Primary Frequency Standard", was given by J. De Prins (University of Brussels). He discussed experiments where the symmetry of double beam masers was made use of to reduce the frequency sensitivity to experimental parameters. From these papers, numbers of the order of 10^{-9} were suggested for the accuracy and 10^{-11} for the resettability of single beam masers and an order of magnitude better for double beam masers.

In 1957, Prof. P. Kusch proposed that a thallium hyperfine structure line may yield a more precise standard of frequency than the use of the cæsium line. The first reported operation of a thallium standard was given at this conference by Dr. Jacques Bonanomi (Neuchâtel Observatory). In his paper, "Design and Performance of a Thallium Frequency Standard", the construction differs from cæsium standards in the following main points: a high (1,000° K) oven temperature, high (14,000 gauss) *A* and *B* fields, and an oxidized tungsten filament detector. In his preliminary attempt, an accuracy was attained which is already comparable to the best accuracy of other kinds of atomic frequency standards.

Dr. Bonanomi presented possibly the most interesting results of the Conference. He showed that the construction problems for a thallium beam machine are not insurmountable, and that there are good reasons to believe that the advantages of a higher frequency and smaller magnetic field sensitivity as compared with cæsium can be realized. Measurements were reported where the whole correction for the magnetic field *C*-field was about 2 parts in 10^{12}. With reference to the unit of time in which the cæsium frequency is 9, 192, 631, 770 c/s, the thallium line frequency was reported as 21, 310, 833, 945·1 c/s ± 1·0 c/s.

Session VIII : Atomic Frequency and Time (Rubidium, Cæsium and Other Matters)

This afternoon session under the chairmanship of Dr. L. Essen (National Physical Laboratory, Great Britain) continued the day's discussion on frequency and time.

A paper by M. E. Packard (Varian Associates), "The Optically Pumped Rubidium Vapour Frequency Standard", reported recent work on gas cell frequency standards and the physics of the quantum mechanical system. Carefully engineered systems have been demonstrated to have high stability with high reliability and small weight and volume.

Frequency stability, which is the important quality of a standard, has been studied over a wide range of averaging and measurement times. A plot of standard deviation of frequency stability shows a broad minimum of $2{\cdot}5 \times 10^{-12}$ for a run of 10 h (24 min averaging time for each measurement); 2×10^{-11} for a run of 10 min (1/4 sec averaging time); and $4{\cdot}5 \times 10^{-11}$ for a run of 160 days.

P. Kartaschoff (Swiss Laboratory for Horological Research) reported results on "Operations and Improvement of a Cæsium Beam Standard Having 4 Meters Interaction Length". By extending the length of an atomic beam frequency standard, the line width is reduced, allowing greater precision of measurement if the signal to noise ratio remains sufficiently high and if other length dependent errors such as *C*-field uncertainty and phase shift are not limiting. He found it possible by using demagnetizable Armco iron shields to reduce errors due to *C*-field uncertainty to $1{\cdot}2 \times 10^{-12}$. Cavity phase shift effects were below $1{\cdot}5 \times 10^{-11}$ and his accuracy was stated to be $\pm 3 \times 10^{-11}$. Two years of comparisons by VLF Standard Frequency Broadcasts showed agreement to about $\pm 1 \times 10^{-10}$ with the United States Frequency Standard.

Manual measurements of cæsium beam resonators are more straightforward and involve less equipment than servo methods, but are also more time-consuming and more dependent on the technique of the individual operator. Servo measurements, however, are potentially affected by many more parameters.

R. E. Beehler, W. R. Atkinson, L. E. Heim, and C. S. Snider (all at the National Bureau of Standards) presented "A Comparison of Direct and Servo Methods for Utilizing Cæsium Beam Resonators as Frequency Standards". This investigation showed that any inaccuracies added to the measurements due to the effects of their servo system parameters are less than several parts in 10^{12}. The precision of measurements has significantly increased to 2×10^{-12} for a 1/2 h average. The servo method is now used for measuring the U.S. Working Standards of Frequency on a regular basis.

William Markowitz (U.S. Naval Observatory), in a paper "The Atomic Time Scale", discussed the system of atomic time, *A*1, derived from the operation of cæsium-beam resonators located in nine laboratories about the world. A re-determination of the cæsium quantum transition frequency, found to be 9,192,631,770 c/s of ephemeris time in 1958, was made, using observations of the Moon through July 1962. This resulted in the same frequency but with the error of observation reduced from ± 20 c/s to ±10 c/s.

The Bell Telephone Laboratories have a programme for improving quartz crystal oscillators. A report on their 2·5 Mc/s and 5 Mc/s oscillators used for standard frequency and time control, "Performance of Precision Quartz Crystal Controlled Frequency Generators", by R. A. Sykes, W. L. Smith and W. J. Spencer was given by Mr. Sykes. Recent improvements in oscillator, oven and crystal unit design have produced 5-Mc/s oscillators with drift rate less than 1×10^{-10} a day, while the 2·5-Mc/s oscillator drift-rate is less than 1×10^{-11} a day.

The short-time stability (10 msec) of both types of units when measured in the Gc/s range appears to be of the order of a few parts in 10^{10}.

Addition of a getter in the quartz crystal unit appeared to have a marked effect in reducing frequency shifts caused by oven and oscillator shut-off.

H. F. Hastings (U.S. Naval Research Laboratory) and P. B. King (Aircraft Radio Corporation), in a paper "Technique for Precise Measurement of Short- and Long-term Stability of Oscillators", discussed improvements in the error multiplication system of frequency measurement. In this system the unknown frequency and standard frequency, nominally the same, are multiplied by different factors, in this case 9 and 10. The resulting beat frequency is again multiplied, the resulting process of error multiplications being repeated until sufficient precision is attained.

In the last paper of this session it was shown that there are certain advantages in using relatively short cæsium beams for frequency standards, among them less difficulty in obtaining a uniform *C*-field over a short region and higher beam intensity, although the cæsium line width is made larger by the short interaction time. The performance of such a beam tube was reported by James George (National Company, Inc.) in his paper "Recent Advances in Cæsium Beam Technology and Characteristics of Rabi and Ramsey Cæsium Beam Tubes 17 Inches in Length". The tube uses a new hot wire ionizer relatively free of potassium with a response of 0–500 c/s. The line width is 1,000 c/s with only 1·5 μW necessary to excite the transition using a single Rabi type cavity. The standard deviation from the controlled output frequency of an 'Atomichron' using the 17-in. beam tubes (Rabi and Ramsey types) was a few parts in 10^{11} and in 10^{12} respectively. This development now permits the realization of 'Atomichrons' small in size, weight and power consumption for use in highly portable systems.

Unit of Time and Velocity of Light

Prof. N. F. Ramsey served as chairman of the informal evening session at which two subjects were discussed: "An Atomic Definition for the Unit of Time" and "Determination of the Velocity of Light".

William Atkinson (National Bureau of Standards) presented results which were of importance to the problem of keeping atomic time scales and to time and frequency comparisons by very-low-frequency broadcasts. He discussed how clocks driven by quartz oscillators would be subject to fluctuations which depend on the spectra of the phase fluctuations of the oscillators, and gave results of measurements on typical oscillators which show an increasing amplitude of fluctuation as the fluctuation frequency decreases. He presented results of comparisons by means of *WWV* of the National Bureau atomic time-scale and the Naval Observatory *A*1 atomic time-scale. He also pointed out that caution must be used in applying statistical treatment to data from very-low-frequency comparisons since his analysis showed that the data did not generally exhibit a gaussian distribution.

There was a considerable amount of discussion concerning what transition would be used for an atomic definition of the second as well as some of the problems in relating atomic time to astronomical time. The unit of time-interval, now identical with the second of Ephemeris Time, may be re-defined in 1966 in terms of an atomic transition by the General Conference of Weights and Measures. This would recognize formally the situation that now exists, that atomic clocks are used to provide the unit of time-interval where very high precision is required. However, the requirements for providing Universal Time along with the interval of atomic time will continue (Universal Time is a time-scale based on the rotation of the Earth). Prof. Ramsey, by way of summary, stated that in order that the Consultative Committee for the Definition of the Second may make a firm recommendation by 1966 to the International Bureau of Weights and Measures, the particular transition should be fairly well settled on in the next two years. Cæsium now appears to be a good possibility with a long head start, but there are still others in the running. The atomic transitions, thallium, cæsium and hydrogen, look a little more favourable than molecular transitions such as ammonia. In the meantime, astronomers are working hard to supply the best value for close agreement between the Ephemeris and Atomic Second.

When the Atomic Second is adopted it will very closely agree with the Ephemeris Second, but will be independent of the latter.

The second part of the evening discussion was devoted to experiments in progress, or proposed, for determining the velocity of light. The points were raised that such experiments should have as their aims an increase in the present accuracy of the value of *c* and a verification of the hypothesis that *c* is independent of frequency.

An experiment in progress at the National Bureau of Standards Boulder Laboratories and reported by Mr. R. C. Baird utilizes a micro-wave interferometer of the Michelson type to measure phase velocity of 50-Gc/s electromagnetic waves. The primary difference between this interferometer and earlier ones is the region of operation. The Bureau model operates in the Fresnel or near field region. This necessitates the use of a diffraction correction and this is calculated on the basis of a rigorous solution of Maxwell's equations. The accuracy of this determination will be about 3 or 4 parts per 10 million, which is equal to the best determination to date. One of the most useful results of this work is the analysis of the diffraction correction; another feature of value is that the experiment represents an independent determination at a different frequency and uses a different method from previous experiments.

Dr. Boyne of the National Bureau of Standards, Washington, analysed a novel method utilizing an optical maser as a source. The method would necessitate the measurements of the difference frequency of two gas laser lines of the helium–neon system. This frequency is about 1,600 Gc/s, and Dr. Boyne explained the use of a modified cathode ray-travelling wave tube using a photo cathode to measure this accurately.

Dr. Essen (National Physical Laboratory, Great Britain) commented on his experiments aimed at determining lengths in terms of frequencies, utilizing the velocity of light. He is of the opinion that their determination of c will be to a few parts in 10^8.

During this part of the discussion Mr. McNish made the point that present measurements of light speed are all less accurate than length and time-interval measurements. Hence attempts to define lengths in terms of a frequency standard and an assumed light speed would make length determinations more inaccurate than they ought to be in comparison with present techniques based on an independent length standard (wave-length of the krypton line). Dr. Ramsey stated also that since we have an *MLT* system, the value of the speed of light, although a theoretically invariant constant, must still be determined experimentally.

There was some discussion of the practical necessity for knowing the speed of light to a high accuracy, and Dr. Richardson expressed an interest in finding out just what are the present theoretical limitations, in concept, on the constancy of the light speed c. Dr. Shimoda noted that estimates of the limit of the deviation of the Coulomb law from the inverse square seem to yield a figure of 1 part in 10^{16} as an interesting region for investigation. Such a deviation would imply a non-zero photon rest mass and consequently a dispersion in the speed of light. Besides atomic effects of this kind, Richardson also had in mind a general relativistic limitation on our definition of standards.

Any co-ordinate systems, as a result of the curvature of space time predicted by general relativity theory, must also partake of this distortion. Hence, the co-ordinate speed of light will differ from point to point due to gravitating masses. However, the speed measured over short enough distances in a freely falling, that is, an inertial reference frame will always be the same invariant, c. A co-ordinate speed could differ, near the Earth by 1 or 2 parts in 10^9, from the co-ordinate value at a large distance from the Earth, or from the value measured in an inertial system. However, a suitable choice of the space and time co-ordinates can, of course, be made so that in any small enough region the co-ordinate speed and the proper light speed are equal. But this cannot be done everywhere simultaneously using only one co-ordinate system. Thus, methods of dissemination of time signals must take this limitation into account.

Such relativistic effects as this furnish us with additional reasons why an atomic standard for time, as well as one for length, should be adopted. Such standard units are definable over restricted regions of space and time in such a manner as to satisfy the conceptual requirements of relativity theory.

Session IX : Micro-wave Power and Attenuation

This session, presided over by K. Tomiyasu (General Electric Co.), had seven papers on microwave power and two on microwave attenuation. Each was concerned with precision measuring techniques and standards.

The session opened with an invited paper by Prof. H. M. Barlow (University College, London), who surveyed the instruments and techniques recently developed in Great Britain for measuring power. Some of these new measuring techniques are attractive in that they do not require absorption of the incident energy, as do ordinary bolometric techniques. The first device is an oscillating dipole, placed in a resonant cavity, and arranged with a fine suspension fibre and optical deflexion measuring system. Peak deflexion of the dipole in response to the torque that results when pulsed power is applied to the cavity can be related to the power-level.

Several of the difficulties inherent in present Hall-effect devices were discussed, and a new method which offers hope of eliminating some of these troubles was proposed. Finally, a new type of electrostatic torque wattmeter, developed by the speaker, was described. It offers the advantage of calibration in terms of mass, length and time, and is thought to be capable of correct power measurements regardless of the nature of the load.

S. Okamura (University of Tokyo) discussed the work being done in Japan on a device similar to the oscillating dipole type designed for use at 35 Gc/s. The basic unit has been refined by the addition of a special photoelectric deflexion-measuring system. Both transmission and cavity types of microwave wattmeters based on the magneto-resistance effect were also described.

Investigations into the use of Hall-effect devices to measure microwave power densities up to 1 W/cm^2 were reported in a paper by R. A. Leavenworth, J. Maczuk, and R. F. Schwartz (University of Pennsylvania). Their studies were primarily concerned with the use of such devices as broadband collectors and transducers of the microwave energy, operating without tuning over the range 0·1–10 Gc/s. Meaurements made covered the range from 0·3 to 3·4 Gc/s and sensitivities of about 1·28 μV/100 mW/cm^2 were obtained.

A paper by K. Sakurai and T. Maruyama (Electrotechnical Laboratory, Tokyo) described a mm-wave microcalorimeter of interesting design. The instrument uses a single load, as opposed to the thermally balanced type developed at the National Bureau of Standards, and uses an electronic servo system to maintain the temperature difference between the load (bolometer mount) and the reference (the shell of the calorimeter) less than 10^{-5} °C. This is accomplished by means of a Peltier thermoelectric cooler controlled by a differential thermopile between the two calorimetric bodies. The current of the cooler furnishes the data in the system. The system measures the effective efficiency of a bolometer mount with an absolute accuracy of 0·6 per cent, making possible accurate power measurement in the 35-Gc/s region.

The next two papers demonstrated the importance of microwave pulse power measurements. The first, by C. A. Denny, C. L. Mavis and C. J. Still (Sandia Corporation), described two systems in which a sample of the unknown pulse is compared with an identical sample of a known generator, using a coherent detector for level comparison. The two methods differ from each other in that one samples the unknown signal directly with a crystal switch while the other uses a heterodyne receiver with a pulsed intermediate frequency amplifier. The pulsed receiver system can be used down to -60 decibels referred to 1 mW with an accuracy of 5 per cent. Somewhat better accuracy is obtained at higher levels. The crystal switch is usable with pulse widths greater than 200 nsec, and the pulsed receiver may be used with pulse widths greater than 350 nsec.

The second paper dealing specifically with peak pulse power measurement was prepared by P. A. Hudson, W. L. Ecklund and R. A. Ondreika (National Bureau of Standards, Boulder). Their system is very similar to that described by C. A. Denny, but features a narrower sampling pulse, typically 100 nsec wide. This, together with the pulse delay and trigger circuitry of the system, permits resolution of the unknown pulse shape as well as measurement of the peak value for pulses longer than about 1 μsec. A special switch design affords greater than 70 db. isolation when open and 1·5 db. loss when closed. The high isolation is necessary to the accuracy of the system, which is given as plus or minus 2·5 per cent. The system is intended for application at levels up to 10 kW peak.

A highly refined and carefully analysed rotary vane attenuator was described by A. V. James (Sperry Gyroscope Co.), who proposed its use in primary calibration laboratories. The design discussed uses a tape wound around the circumference of the rotary drum in place of the usual gear drive. This eliminates the gear backlash and converts the rotary motion to translational motion, where it is measured by means of a dual micrometer mechanism. The translation amounts to 4·5 in. for a 90° rotation and is measured to within 250 μin. A check against an audio-substitution attenuation measuring system showed agreement to within 0·04 db over a 40-db range, in the X band. Calculated limits of error were plus or minus 0·095 db in the range 0–40 db.

A paper by R. F. Clark and B. J. Dean (National Research Council, Ottawa) discussed a precision X-band system capable of an accuracy of $\pm(0{\cdot}010 \text{ db} + 0{\cdot}005 \text{ db}/10 \text{ db})$, with a 40 db dynamic range. The X-band attenuator is compared with a calibrated 30-Mc/s reference attenuator by means of a linear superheterodyne detector. Both frequency and amplitude stabilization are used in the system to obtain for the standard a drift of less than ± 0·005 db per 5 min.

A new and unusual method of pulse power measurement was disclosed in a paper entitled "An Elastic Wave Method for the Measurement of Pulse Power Density", delivered by R. M. White (General Electric Co.). The method is based on pulse heating of the surface of a body which is mechanically coupled to a sensor such as piezoelectric crystal. The absorbed energy pulse produces a rise of temperature in the surface of the body which creates an elastic stress wave that propagates through the body to the sensor. Experiments have shown that the effect is due to heating and not to radiation pressure; indeed, the system is much more efficient than one designed to respond only to the radiation pressure. In an experimental X-band detector, an output of 6 mV was obtained from the sensor for a peak pulse power density of 12 kW/cm^2. Experiments were also made with different energy sources, including light pulses from a laser or stroboscopic lamp, and a pulsed beam of electrons in an evacuated chamber. It may be possible to obtain ultimate sensitivities of a few hundred microwatts per square centimetre by using resonant techniques.

Session X : Micro-wave Techniques

Session X on "Microwave Techniques", with Harold M. Barlow (University College, London) as chairman, consisted of six papers.

S. B. Cohn (Rantec Corporation, Calabasas, California) presented the first paper, entitled "Swept Phase-Measurement Techniques with CW and Pulsed Signals", in which he described recent advances in instrumentation for measuring phase shift versus frequency for linear two port devices and phase shift versus control voltage or drive power for non-linear devices. The instrumentation, for either continuous-wave or pulse-modulated signals, had a scale expansion such as to allow errors of only a few tenths degree around 90° for single frequency measurement.

The second paper, entitled "A Phase Measuring System for Short RF Pulses", presented by R. A. Sparks (Emertron, Inc., Silver Spring, Maryland), described a novel technique of measuring the relative phase characteristics of pulsed microwave amplifiers. The method utilizes a two-channel system and the principles of homodyne detection. The capability of handling very narrow radiofrequency pulses with high resolution is obtained through generation of an unusually high offset frequency and the use of a wide band intermediate frequency amplifier. A 100 Mc/s oscilloscope is utilized to display the undetected bipolar signal that contains the translated phase information of the pulsed carrier.

Paper three, "A Technique for Precise Measurement of the Radio Frequency Structure of Pulsed Signals", was given by W. D. Griffin (HRB-Singer, Incorporated, State College, Pennsylvania). The technique described here is capable of detecting a zero-beat to one one-hundredth of a cycle during a pulse. It is based on measurement of the instantaneous relative phase of the pulsed signal with respect to a stable local oscillator (stalo) at approximately the same frequency. This is accomplished by dividing the pulsed signal into two equal parts and heterodyning these in balanced crystal mixers with two equally divided continuous-wave signals from a stalo. Equal path-length is maintained throughout except for a 90° phase shift inserted in the path of one of the two oscillator signals. One mixer output is used as the vertical deflexion voltage on a cathode-modulated cathode ray oscilloscope, while the other is used as the horizontal deflexion voltage. This then produces a unique display of the relative phase of the pulsed signal with respect to the oscillator as a function of time.

The next paper, "Report on Standardization of High-Precision Coaxial Connectors", was presented by D. E. Fossum (Sandia Corporation, Albuquerque, New Mexico). In the present state of the art of coaxial measurement, errors due to connexion uncertainties limit the accuracy of nearly all quantities. The report briefly described the co-operative effort of the National Bureau of Standards and instrument manufacturers with university and foreign laboratories to recommend practices for precision coaxial connectors. Such connectors would be used on standard and high-quality instruments to ensure minimum loss of accuracy in transferring information with a small number of compatible connectors. Such connectors would be made to accuracies now used for precision wave-guide flanges giving voltage standing wave ratios ranging from about 1·002 at 1 Gc/s to 1·01 at 13 Gc/s.

D. Woods (Ministry of Aviation, London) presented the fifth paper, "Improvements in Precision Coaxial Resistor Design". Discussed were: (1) the successful development of cylindrical metal film resistors of uniform surface resistivity with an adjustment tolerance of 0·1 per cent; secular stability, 0·03 per cent; temperature coefficient less than 0·002 per cent/°C, suitable for use with a tractorial jacket in a coaxial mount up to 4 Gc/s; (2) the proposal to apply the technique to the manufacture of conical resistors for use with a cylindrical jacket. The advantages of this type of mount are pointed out, namely, the simplicity of the mechanical construction and the reduction of residual discontinuities to a bare minimum, even to the elimination of the dielectric support in a matched termination, provided a suitable coaxial connector is used, similar to one developed by the author; (3) a simple explanation of the principle of operation of the cylindrical resistor with a tractorial jacket and the conical resistor with a cylindrical jacket in terms of electromagnetic wave propagation over a resistor film surface; (4) the effects of field penetration through the resistive film into the resistor substrate and means for compensating the effect in a precision coaxial resistor.

The last paper, "Microwave Measurements at 150 Gc/s", was presented by J. B. Thaxter (Lincoln Laboratories, Lexington, Massachusetts). Mr. Thaxter discussed methods presently used at his laboratory for the measurement of frequency, power, and impedance in the two millimetre wave-length region of the spectrum. Frequency is measured by heterodyning the unknown with a signal obtained by multiplication from a highly stable low-frequency source. Power at 100–200 Gc/s in the fractional mW range is measured by a water-flow calorimeter utilizing a d.-c. comparison method. Impedance is measured by the usual bridge technique utilizing a hybrid *T* along with a calibrated attenuator and sliding short. Lack of standards in this frequency-range and the component sizes dealt with severely limit the accuracy of measurements in this new field.

Numerous persons, including many of the authors already mentioned, contributed to and reviewed this summary. Their efforts are greatly appreciated.

INTERPRETATION OF MICRO-STRUCTURES IN CARBONACEOUS METEORITES

By PROF. G. MUELLER

Department of Geology, University of Concepcion, Chile, Nuffield Foundation Research Fellow at Birkbeck College, University of London

THE considerable number and variety of microscopical objects within the Orgueil and several other carbonaceous stones were interpreted by some authors[1,2] as of likely organic origin. These conclusions have been contested[3] and critically discussed[4,5].

The aim of the present article is to attempt to cast more light on this controversy through additional evidence furnished from observations under the polarizing microscope of fifteen previously recognized and five new stones with a carbonaceous phase. It was found that the majority of the structures claimed as of organic origin could be readily and quite unequivocally identified as mineral grains.

From the point of view of types and abundance of micro-structures present, the meteorites so far investigated could be divided into three broad classes as follows:

Microstructure type 1: these include the two stones so far examined from compositional group I of Wiik[6]. They are characterized by the presence of troilite plates and abundant glass globules (Table 1). This group includes the Orgueil meteorite.

Microstructure type 2: includes mostly the compositional type 2 of Wiik. In these there are no troilite plates, and the glass globules are less abundant, whereas freely grown, cored olivines are the

most common. This group contains the Mighei meteorite.

Microstructure type 3: consists mostly of the 'low carbon' group of Wiik; it contains no, or very little, glassy structures, and the cored olivines are of the coated or sintered type.

The only meteorite so far examined which does not fall into any of the foregoing groups is Erakote, which consists of radiating, acicular aggregates of a slightly translucent, dark mineral of straight extinction, which has not been identified so far.

It is interesting to note that both the diameters of the high-temperature mineral grains present, and their ratio to the ground-mass of hydrated silicates and carbonaceous phase, do increase with decreasing volatile, carbon, water and sulphur percentage of the stones.

The markedly rounded or globular habits of both the glass and the olivine, etc., microstructures seem to indicate that these solidified when freely suspended in gas. This is reminiscent of conditions prevailing in cases of terrestrial ash eruptions and nuée ardentes, where often the high-temperature pumice grains tend to intermix with low-temperature fragmented matter, as is the case in the structure of the fresh olivine, etc., grains spread throughout the hydrated silicate and carbonaceous phase containing matrix of the carbonaceous chondrites. The markedly more freely formed habits of the grains in meteorites, when compared with those of terrestrial tuffs or welded tuffs, can be explained possibly through these staying suspended for a longer period of time within the gases, due to the lower gravitational field which prevailed on the parent body. The presence of cores in most of the crystals indicates a process of unmixing of impurities during cooling. It is significant that, in the case of the olivine grains, the ratio diameter of crystal/diameter of core remains approximately constant at 5 (compare Figs. 7–12), indicating the unmixing of a reasonably constant proportion of impurities from a spray of essentially 'olivinic' composition.

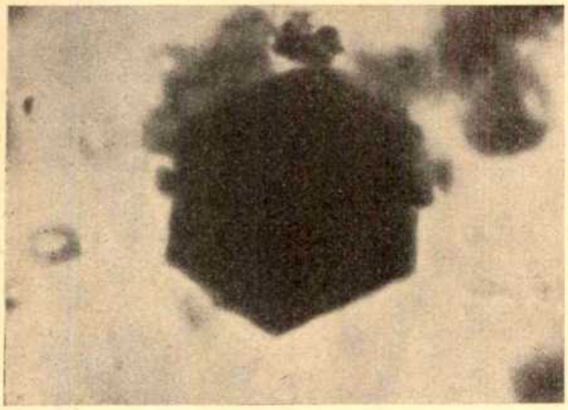

Fig. 1. Troilite plate with two magnetite knobs in diagonal position from Orgueil. (×1,000)

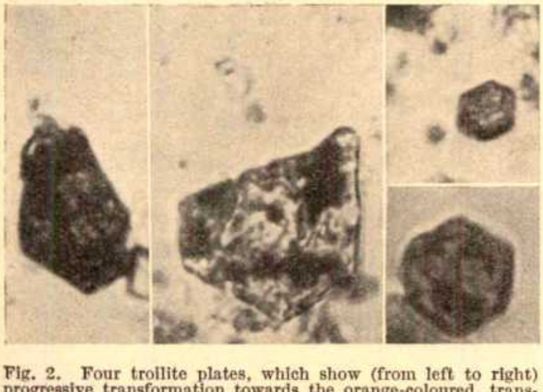

Fig. 2. Four troilite plates, which show (from left to right) progressive transformation towards the orange-coloured, translucent limonite pseudomorph; the upper right-hand pseudomorph shows no more vestiges of the opaque troilite. (×1,000)

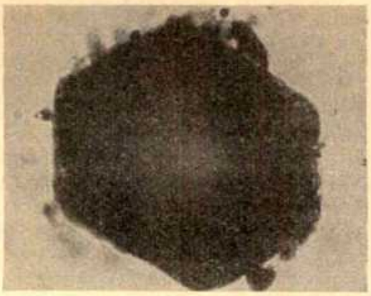

Fig. 3. Troilite plate with incipient oxidation to limonite and three magnetite concretions on alternate faces. (×1,000)

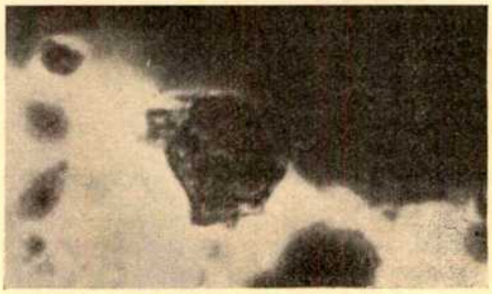

Fig. 4. Limonite pseudomorph with some traces of troilite, and three appendages of lighter and more greyish shade on alternate faces, from Orgueil. (×1,000)

The only microstructures which cannot be readily explained as of mineral origin are the jointed double walled filaments observed in Orgueil[7], which are very rare, and, judging from their fresh appearance, may be contaminations.

The grains found in the meteorites examined divide into three rather broad mineralogical-genetical groups as described briefly here.

(1) *Hexagonal plates of troilite with occasional magnetite overgrowth and their limonite pseudomorphs.* The object of without doubt the greatest theoretical interest, illustrated by Claus and Nagy[1], is the orange-brown, hexagonal, rounded plate with the three roughly cylindrical-conical protrusions of greyish-brown colour, situated at alternate sides. Its morphology is too dissimilar from that of any known terrestrial microfossil to be conceived as a possible contamination; on the other hand, a mineralogical interpretation does not seem to present itself at first sight. The previously noted[3] similarity between the foregoing structure and the hexagonal. magnetic opaque troilite plates present does not account for the colour and the rather symmetrically arranged protrusions.

It was found in the course of the present investigation that a perfectly gradual transition exists between the relatively larger, 30–50μ diameter, troilite crystals, which show invariably brown surface tarnishing, and the smaller, 10–20-μ plates, which are completely or almost completely converted to the limonite pseudomorphs (compare Figs. 1 and 2), which, in turn, is identical in all respects with the central plate of the structure of Claus and Nagy. The detection of a very rare troilite plate, with three rather cylindrical overgrowths of magnetite aggregates on alternate faces (Fig. 3), appears to give decisive evidence for the complete mineralogical derivation of the object in question. In oblique reflected light, the central plate appears concave and stained brown, whereas the three magnetite knobs are lustrous, black—which fact might account for the differences in colour between the pseudomorphosed plate and its protrusions, as shown in Fig. 4.

The control of nucleation of the magnetite is not a crystallographic one, as the troilite does not contain a trigonal element in its symmetry, but is due to the fact that a once nucleated magnetite aggregate on a given face would absorb so much substance from the setting that nucleation on the two neighbouring faces would be unlikely. As a result of this, troilite with magnetite on one face only, on the two opposite faces (Fig. 1), or on two or all the alternate faces would be theoretical possibilities, and, indeed, all these types of overgrowth have been observed.

The genesis of these freely grown troilite plates may be explained through a late-stage penetration of the loose matrix of the meteorite with hydrogen sulphide containing gases, the latter reacting with the abundant Fe^{++}, producing ferrous sulphide. This process is further indicated through the presence of numerous calcite, gypsum, sulphate of magnesium, etc., veinlets which render the aspect of the stone very similar indeed to that of a specimen of terrestrial ash traversed by a fumarola vent. As a rule the latter contains innumerable pyrites cubes, which in turn may oxidate, producing the familiar limonite pseudomorphs, and, indeed, a few of such oxidated pyrites cubes were encountered in the Orgueil meteorite (Fig. 5). The fact that both the crust and the central portions of the Orgueil meteorite proved to contain limonite pseudomorphs after troilite seems to indicate that at least part of the oxidation occurred in outer space.

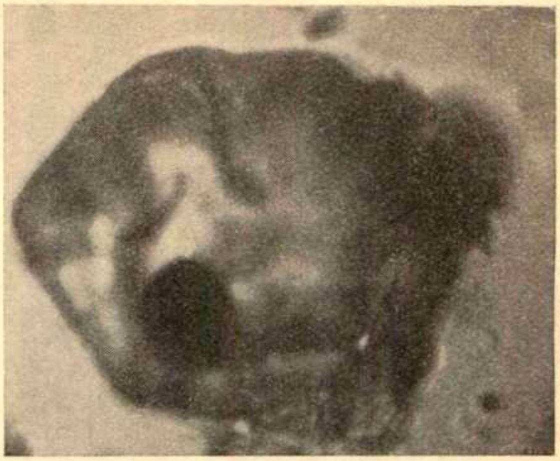

Fig. 7. Cored olivine crystal from Mighei. (× 1,000)

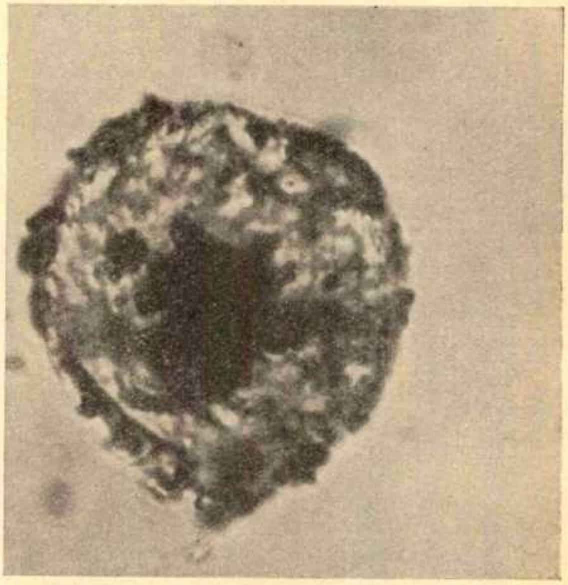

Fig. 8. Cored and sheathed globule of olivine from Alais. (× 1,000)

(2) *Globules, etc., of glass.* Most of the stones proved to contain rather crinkled globules (Fig. 6) or expanded threads—'Pele's hairs'—of glass, with N: 1·5–1·52, only occasional slight stain-birefringence and colours ranging from pale yellow to greyish-brown; all these properties are well within the range of glasses described previously from meteorites. A few of the globules were heated to about 700° C, with a filament directly under the microscope, without any change being observed. It seems that most of the globular objects illustrated by Claus and Nagy[1] may belong to this group, although, as the absence or presence of birefringence was not mentioned in the paper, some of them may belong to group 3, which follows.

(3) *Single crystals (mainly olivine) of rounded or globular habit.* Crystals or occasionally also crystalline aggregates of the opaque minerals (mostly magnetite, troilite and nickel-iron) are always of markedly globular or ellipsoidal habit. The very common olivines (identified through their optical properties,

habits, cleavage angles, etc.) show in all the meteorites an approximately constant radius of rounding of some 5μ; as a result of this the crystals of less than 18μ diameter are markedly globular.

An interesting feature of most of these olivine crystals—and occasionally also of the rarer felspar, enstatite and glass globules—is the presence of one or more globular cores (Figs. 7–12). The most common core is opaque, of low reflectance and granular appearance; it seems to consist mainly of fine-grained magnetite with other impurities. Cores of bronze colour (troilite ?) and of high metallic reflectance (nickel-iron ?) were also noted, usually within the multi-cored crystals, in which the common, black core is rarely if ever absent. Sometimes light-coloured glassy cores and gas bubbles appear as well. The study of thin sections of Murray revealed that sometimes the core of impure magnetite contains a small core of silvery lustre (nickel-iron ?), producing a globular crystal which resembles closely the models of internal structure of the Earth. This similarity is even more accentuated in the case of the 'coated globules' (Figs. 8, 9, 10), which apparently contacted the matrix of hydrated silicates and carbonaceous matter in a still tacky state, their outer sheaths being rather analogous to our sediments. Olivine globules, expanded into 'Pele's hairs' (Fig. 10), have been observed as well.

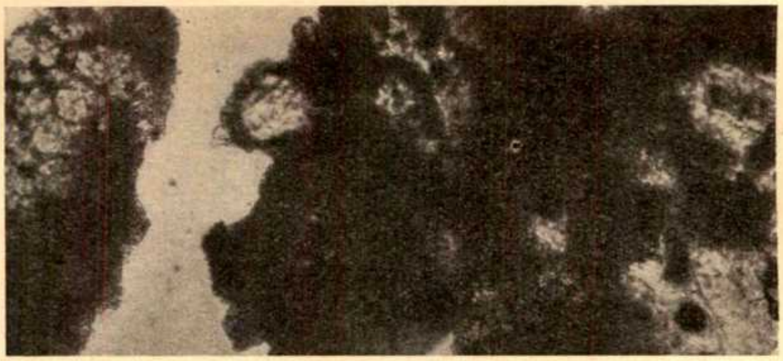

Fig. 11. Several olivine globule-chondri in Mokoia, showing partial sintering of the individual cored crystals

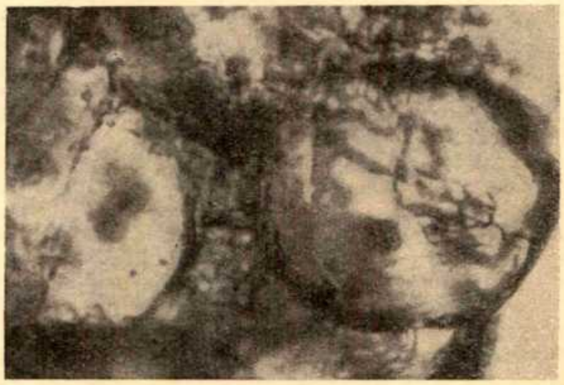

Fig. 12. Cored olivine globules in enstatite, from Indarch. (×1,000)

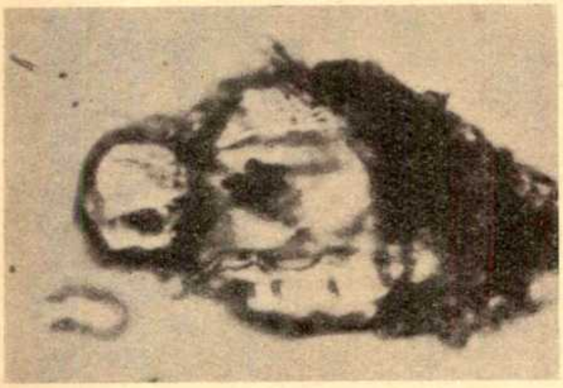

Fig. 9. Two cored and sheathed olivine globules from St. Caprais; note smaller size of core in smaller globule. (×1,000)

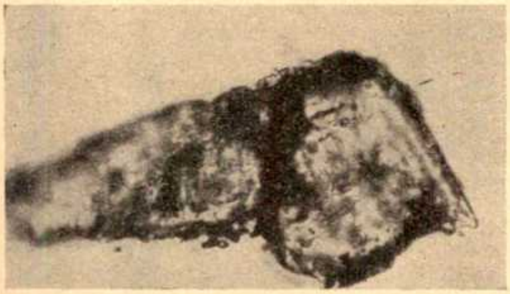

Fig. 10. Expanded olivine globules from Renazzo, with cores (out of focus) and partial sheaths. (×500)

With the increasing mechanical strength and decreasing carbon content of the meteorites, the individual cored crystals tend to sinter into larger globule-chondri. The sectioned grains of Mokoia, illustrated in Fig. 11, show several of these with diverse grades of sintering of the cored olivines and, also, occasional opaque globules, including the formation of single olivine crystals in which part of the original cores, however, apparently still remained separated. Sometimes the globules tend to decrease in size when proceeding from the centre towards the surface of the chondrule. Globular olivine crystals embedded in enstatite were also observed (Fig. 12).

The extensive range of stones examined and the consistence and graded character of the mineral grains observed in them would seem to remove the necessity to postulate an organic origin for any of them. The problem of how they actually originate and their relations to carbonaceous matter in the meteorites will evidently require more detailed and systematic study before any general theory of their genesis can be safely postulated.

The work described here was carried out with funds made available by the Nuffield Foundation. I thank Prof. J. D. Bernal for most inspiring and fruitful conversations on the subject and, also, Prof. J. Orcel, of the Natural History Museum, Paris, for his kind help in placing at my disposal samples of carbonaceous chondrites from his Museum.

SCIENTIFIC METHOD AND THE NATURE OF TECHNOLOGY

By Dr. F. LYTH HUDSON

College of Science and Technology, Manchester

TECHNOLOGY has been defined as "the scientific study of the practical or industrial arts" and science as "truth arrived at by observation, experiment, induction" (*Oxford English Dictionary*). A scientist is one who applies scientific method in the fundamental natural sciences while a technologist is one who engages in the scientific study of the industrial arts. He is a kind of practical scientist. A technologist has studied the fundamental principles of his chosen technology and should be able to use his knowledge and experience to initiate practical developments[1].

It is evident from these definitions that a technologist must be a scientist though a scientist is not necessarily a technologist. In considering the nature of technology one must therefore look into the difference between the two. What must a scientist do to become a technologist ? It is clear from the definitions that he must study the practical and industrial arts; but, although his study of these is supposed to be scientific, he must learn to understand something of the crafts and craftsmen associated with his chosen technology.

In studying crafts one must learn to appreciate rule of thumb. Sir David Pye, in his address to the Institution of Mechanical Engineers (October 1952), said: "The art of engineering includes a very great deal that lies outside formulated theory. The rule of thumb plays and will always play an important part; and rules of thumb are accumulated by experience". When scientists choose cloth from a pattern book for a new suit they are not likely to apply any scientific tests but will almost certainly feel the cloth between the fingers and thumb after inspecting its colour. What can one find in this way ? If the ordinary buyer can obtain useful information in this way, the buyer skilled in the arts can learn much more. Enormous quantities of manufactured goods and articles are bought and sold after simple subjective tests of this kind. A good technologist must, therefore, try to acquire as much rule of thumb as he can, and as quickly as he can.

He must also learn that in the real industrial world there is seldom a unique solution. Unlike the idealized systems of the pure scientist where chemicals are pure and variables limited he must cope with mixtures of impure materials and with systems containing numerous variables. There are, nevertheless, several unifying principles running through technology. Scientific method should be the same in its essentials wherever it is applied and and it is very important to understand the way in which it is applied in industry.

As used in a straightforward experiment in a school or university laboratory scientific method may be represented schematically by Fig. 1. An experiment is designed, possibly after a survey of the literature, in order to test a particular hypothesis. The experiment is executed, and any conclusions drawn from the observations made are considered along with the hypothesis. In the terminology of modern automatic control theory, the conclusions may be said to be fed back into the hypothesis. If they are considered along with existing theory this will be derived from a survey of the literature and also fed back into the hypothesis. After this a new or revised hypothesis may be drawn up and the process repeated. The process is essentially cyclical, and each part of the cycle is equally essential. Extra information on side-issues may be obtained from the observations. According to the popular Press, discoveries result from chance observations but a chance observation implies the presence of an observer. A scientific experiment carried out in the presence of a skilled observer may easily lead to useful chance observations but the observer must be there.

Many industrial experiments and indeed much industrial planning can be analysed according to the scheme shown in Fig. 2. Someone in authority, shown as M.D. (managing director), puts forward a problem or idea for investigation. This is passed to the appropriate experimental officer or technologist through the accepted channels of communication. A survey of the literature will, of course, include existing company reports. Some industrial experiments may be criticized on the grounds that too little effort is made to record data in such a way that they can be published for the general benefit. Nevertheless, an industrial experiment follows just the same cyclical course as any other scientific experiment, and the conclusions must again be fed back into the original idea. After several cycles each involving reconsideration of the problem in the light of the observations

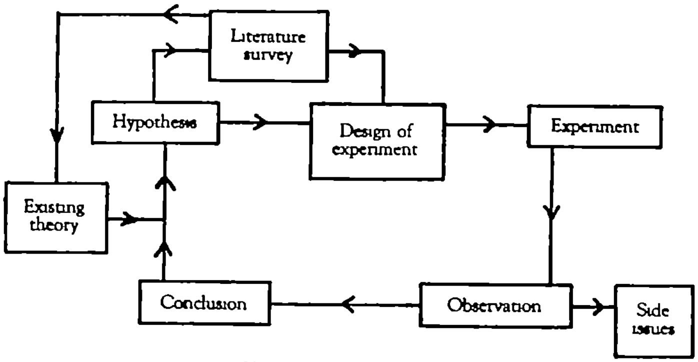

Fig. 1. Scientific method

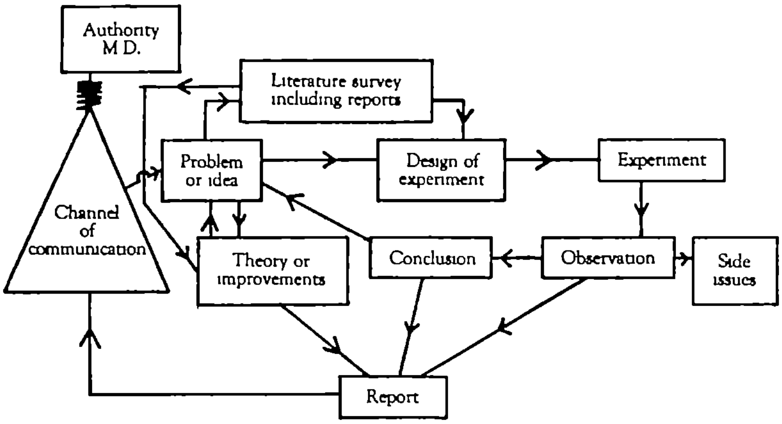

Fig. 2. Industrial research diagram

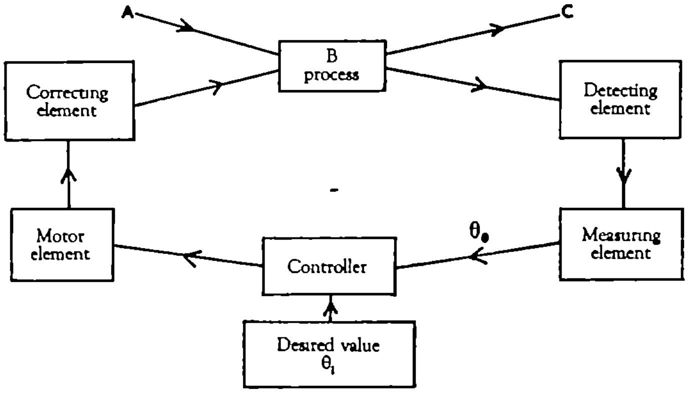

Fig. 3. Automatic control

made and the existing literature it may be possible to suggest some improvements. The industrial equivalent of the pure scientist's 'new theory' is often just 'improvements', and "improvements in and relating to . . . " has become standard jargon in the titles of patent specifications.

At this stage in the technological process a report must be written. When written the report must be fed back through the official channel of communication to the particular authority who originally called for the investigation.

If no report is written at this stage, the work is quite useless industrially. It is essential that the authority—M.D. in Fig. 2—who initiated the work should receive a report on which he can act. Only the initiating authority will have sufficient power in the manufacturing or sales organization to take any action, and unless the report reaches him, in a form which he can assimilate and use, the work might just as well not have been done.

It is at this stage that many young scientists in industry fail. They have been taught by pure scientists whose aim in research is publication. The comparison of the conclusions with the original hypothesis in order to develop new theory completes the pure science cycle of Fig. 1. After that, it is up to others to read the publication and take action if they think fit. There is no obligation on the scientist to put his conclusions in simple English to encourage them to read it—the reverse is indeed often the case.

In industry this method will just not do. The authority is often a layman and invariably busy so that the report must be well written, well summarized and emphasize the action required rather than the prolonged processes by which the conclusions have been reached. Owing to the difficulties to be overcome at this particular stage of the feed-back required in the industrial cycle, the 'channel of communication' has been shown as complicated in Fig. 2 and as containing a resistance. It is most important that the report should be so written that it overcomes this resistance and that the young scientist should understand that his responsibilities do not end until the report has either been discarded or translated into action. If it does result in action he may himself be appointed to develop the processes resulting from it.

Stimulated by authors such as Parkinson[2] there is a tendency to assume that anyone who is 'chair-borne' is not doing useful work. This attitude is particularly prevalent in the less-enlightened industrial laboratories. Actually as more apparatus is invented and particularly more recording apparatus, the time spent in experimentation is bound to decrease and the time spent on interpretation to increase.

In the simplest of industrial scientific experiments, for example, routine control by physical chemical testing, the information may be 'reported' merely by a written entry in a book or a spoken message over the telephone, but the essential principle still remains. It must be 'fed-back' as in Fig. 2 to someone with the authority to take a decision on the process being controlled.

Those responsible for directing this kind of work should always consider whether it could be done better by an automatic controller (Fig. 3). In a process controller the detecting element working in the plant (for example, a thermometer) passes information to the measuring element (for example, a pressure gauge connected directly or through relays with the thermometer). In the controller the measured value θ_0 is compared with the desired value θ_i, and the difference between the two (error) used to actuate a motor element (such as a rubber diaphragm balanced against a spring by air pressure) which will move the correcting element (a valve supplying steam to the process).

This is a very elementary example of the partial application of scientific method. The negative feed-back is there, the observation is compared with the desired (or theoretical) value and action is taken to correct the process, so as to make it produce more closely the desired result. The element of induction, argument from the particular to the general and the development thereby of new theory or knowledge, is absent and the application of scientific method is only partial.

Action by an automatic controller is rapid; routine control by laboratory analysis is slower, and for this reason more wasteful in both time and material; but both emphasize the great importance of negative feed-back. Anyone directing simple routine control should consider the theory of automatic controllers, whether he is able to use controllers or not. Speed of feed-back is so important that it may be worth sacrificing accuracy in order to attain it. Methods should always be under review to see if they can be simplified and speeded up.

Enough has been said to show that scientific method is fundamental to any technology. What, if any, are the other fundamentals ? Here it is desirable to set up the concept of the 'ideal technologist', unattainable in practice just like other ideals. The ideal technologist would be well versed in mathematics and the fundamental natural sciences, physics and chemistry. He would also be an engineer and a biologist. He will be working in industry and be familiar with administration in all its branches, particularly sales, economics, accounting, sociology, personnel management. As Revans[3] has said, in order "to make a steady hundred tons a day" of sulphuric acid "it is probably much better to know how to get one's maintenance engineers to work hard at the week-end than it is understand the surface properties of vanadium pentoxide; it is quite surprising—especially to young graduates—how much easier it is to be informed about catalysts than to understand the behaviour of riggers or pipe fitters". The ideal technologist must clearly be a craftsman too.

In practice, of course, the ideal technologist does not exist, and industry is served by experts in the various crafts, arts and sciences on which it depends. It is often said that some of these experts, particularly those engaged in research, tend to learn more and more about less and less until they know everything about nothing. Others may, having started as experts in one subject, gain information, by accretion or by deliberate learning, in some or all of the other subjects important to their particular industry. It is again said that those who get far enough up the industrial administrative ladder have to learn less and less about more and more until they know nothing about everything. This is not an unfair picture of the end-state of a successful executive. If he is a technologist as well as an executive he must have started with, or acquired a knowledge of, one of the sciences sufficient to equip him with a knowledge of scientific method.

We are now back at the original question: Which of the sciences ? Are there really any fundamentals other than scientific method itself ? Many writers on this subject have assumed that there are, but it is usually found that the chosen fundamental science is the one with which the particular writer started himself. This, too, is usually chemistry or engineering according to the nature of the industry. Either of these sciences may be learned up to an appropriate standard at a university or technical college; each of them is served by an adequate number of professional institutions. Having started in either of them a graduate is well placed to pick up the 'know-how' of the industry he serves. Over the past thirty years physicists and mathematicians have entered industry in much smaller numbers than chemists and engineers, but are now in great demand. It is not surprising, then, that one frequently hears that physics is fundamental to all technology. If, however, fundamentals vary according to the person defining them can they still remain fundamental ? One is left with the view that there is only one real fundamental in technology, and that is scientific method itself.

This is not to deny the importance of the experts in the sciences already listed; but it is most important to remember that each science as taught in a three- or four-year university course is only a tiny selection from the almost illimitable field of knowledge. It becomes conventionalized, rationalized and reduced to almost standard proportions simply because the amount a student can be expected to assimilate usefully in three or four years is more or less the same all over the world. It is three- or four-year brain capacity that produces the arbitrary limits between the fundamental sciences—not anything inherent in the sciences themselves.

If this view is once accepted, the number of subjects which can be properly taught under the heading 'technology' ceases to be limited. One must first teach the real fundamental—scientific method. One must then teach as much as one can of the conventional (not fundamental) sciences most appropriate to the industry which requires the technologist. One must put in the bare minimum of industrial 'know-how' to enable the students to take advantage of vacation periods spent in industry. In content a course of this kind may be broader than a normal science course but will otherwise not be very different. In intent it will, however, be different. It is designed primarily to train men for industry and not for academic research.

The well-trained technologist must be prepared to take methods from various branches of science, and, if, as is likely, he is not expert in them all himself, to employ, or in any event to take advice from, men who are. He should therefore strive to appreciate the methods used in more than one branch of science.

The conventional knowledge of to-day is liable to become the classical knowledge of to-morrow. It was a certain ecclesiastic (a prebendary of Durham—c. 1870—quoted by B. V. Bowden in *Proposals for the Development of Technology*, published by the College of Science and Technology, Manchester, in 1956) who said that "the advantages of a classical education are two-fold; it enables us to look with contempt on those who have not shared its advantages, and it fits us for places of emolument, both in this world and the next".

When this was written it was true that a knowledge of Latin and Greek was essential for places of emolument. Latin was fundamental to all knowledge, and educated men had to learn it to understand each other. In industry to-day, however, the classically educated literate but 'innumerate' leaders of yesterday are being replaced by the 'numerate' (and one hopes not illiterate) leaders of to-day. ('Numerate' and innumerate' are defined in the *Crowther Report*, 15. A report of the Central Advisory Council for Education (England). Ministry of Education, 1 (H.M.S.O., 1959).) Physical science, so far as we understand it, is therefore conventional. It is important and necessary in technology to-day. This, however, does not really make it fundamental, and it is safest to assume that the only fundamental is scientific method itself.

I thank Mr. W. P. Scott. who inspired this article. It is based on some lectures given, under titles chosen by him, to a group of graduate trainees in the Wiggins Teape group in 1957 and has been discussed with him several times since then.

NEWS and VIEWS

The Royal Society: Officers for 1963

At the Anniversary Meeting held on November 30, Sir Howard Florey, professor of pathology in the University of Oxford, was re-elected president.

The other officers re-elected for the ensuing year were: *Treasurer*, Lord Fleck, formerly chairman of Imperial Chemical Industries, Ltd.; *Biological Secretary*, Sir Lindor Brown, Waynflete professor of physiology in the University of Oxford; *Physical Secretary*, Sir William Hodge, Lowndean professor of astronomy and geometry in the University of Cambridge; *Foreign Secretary*, Sir Patrick Linstead, rector of the Imperial College of Science and Technology, London.

Other members of Council elected (or re-elected) were: Mr. F. C. Bawden, director of Rothamsted Experimental Station; Mr. G. B. R. Feilden, group technical director, Davy-Ashmore, Ltd.; Prof. E. F. Gale, professor of chemical microbiology in the University of Cambridge; Sir William Glanville, director of road research, Department of Scientific and Industrial Research; Prof. W. K. Hayman, professor of pure mathematics in the Imperial College of Science and Technology (University of London); Prof. E. L. Hirst, Forbes professor of organic chemistry in the University of Edinburgh; Prof. D. Lewis, Quain professor of botany in University College (University of London); Dr. P. B. Medawar, director of the National Institute for Medical Research; Prof. A. A. Miles, director of the Lister Institute and professor of experimental pathology in the University of London; Prof. W. T. J. Morgan, deputy director of the Lister Institute and professor of biochemistry in the University of London; Prof. C. F. Powell, Melville Wills professor of physics in the University of Bristol; Prof. F. W. Shotton, professor of geology in the University of Birmingham; Prof. J. E. Smith, professor of zoology at Queen Mary College (University of London); Sir Gordon Sutherland, director of the National Physical Laboratory; Sir Graham Sutton, director-general of the Meteorological Office; Dr. H. W. Thompson, university reader in infra-red spectroscopy in the University of Oxford.

(Publication of the presidential address and award of medals at the anniversary meeting of the Royal Society has been deferred until the issue of December 15.)

Chemistry, Physics and Metallurgy at the Royal Aircraft Establishment: Dr. B. P. Mullins

As from November 19, the Chemistry Department and the Metallurgy and Physics Department at the Royal Aircraft Establishment, Farnborough, became amalgamated into a Chemistry, Physics and Metallurgy Department. Dr. B. P. Mullins, at present head of the Chemistry Department, has been promoted to deputy chief scientific officer and head of the new Department. The present head of the Metallurgy and Physics Department, Mr. L. G. Carpenter, who was recently promoted on individual merit to deputy chief scientific officer, is being partially relieved of administrative responsibility, in accordance with the aims of the individual merit promotion scheme, by appointment as head of the Physics and High Temperature Materials Division in the new Department. Dr. Mullins was born in 1920 and educated at Shooters' Hill School, London, which he left when sixteen to join the Engine Branch of the Air Ministry. At nineteen, after two years' attendance at the Woolwich Polytechnic Evening Institute and a year's private study (spent as a Ministry of Aircraft Production evacuee in Harrogate) he obtained a London B.Sc. degree in physics, chemistry and mathematics. He immediately commenced research in the Engine Department of the Royal Aircraft Establishment, Farnborough, where at twenty-two he became head of the Fuels and Lubricants Laboratory. After a year's research on high-vacuum gas analysis under Prof. R. G. W. Norrish at the University of Cambridge on secondment, he returned to Farnborough, where between 1944–60 he undertook physical and physical–chemical researches in the field of combustion science at the National Gas Turbine Establishment (formerly Power Jets, Ltd.). At thirty-one, as a principal scientific officer and having just been awarded an external Ph.D. degree in fuel technology by the University of London, he began to widen his interests, and at thirty-three was appointed the first head of the Chemical Physics Department at the National Gas Turbine Establishment, where he remained until July 1960, when he was appointed head of the Chemistry Department at the Royal Aircraft Establishment. During the mid-1950's Dr. Mullins was U.K. member and chairman of the Combustion and Propulsion Panel of AGARD–NATO.

Physical Chemistry at Leeds: Prof. P. Gray

Dr. P. Gray has been appointed to a personal chair in physical chemistry in the University of Leeds. Dr. Gray was educated at Newport High School and Gonville and Caius College, Cambridge, where he obtained first-class honours in Parts I and II of the Natural Science Tripos in 1946. Following graduation, he was engaged in research in the Department of Physical Chemistry at the University of Cambridge from 1946 until 1951. He was elected to the Dunlop studentship in 1946, and awarded a Ph.D. in 1949. In the same year the Ramsay Memorial fellowship was awarded to him and he was elected a Fellow of Gonville and Caius College. In 1949 he was appointed University demonstrator in chemical engineering. Dr. Gray joined the staff of the University of Leeds in 1955 as lecturer in physical chemistry and received in the same year the Meldola Medal of the Royal Institute of Chemistry. The title of reader was conferred on him in October 1959. He was awarded a Commonwealth Bursary in 1958 and went as visiting professor to the University of British Columbia in Vancouver. The Marlow Medal of the Faraday Society was conferred on him in June 1959. Dr. Gray's research work at Leeds has been in several fields. These include the study of flames and explosions, work on thermochemistry, thermodynamics and heat transport, and the study of free radicals.

Directorship of Twyford Laboratories, Ltd.

The director of Twyford Laboratories, Ltd., Dr. H. D. Kay, has announced his retirement as from the end of the year, when he will have completed his pioneering three-year term on the board of the company. As from January 1, Dr. F. A. Robinson, chairman of Crookes Laboratories, Ltd., will be the managing director of Twyford Laboratories, Ltd., but will also continue as chairman of Crookes Laboratories. Twyford Laboratories, Ltd., a wholly owned subsidiary of Arthur Guinness Son and Co., Ltd., was established to conduct fundamental research into animal and plant biochemistry and microbiology, and was recently expanded to enable research into chemotherapy and virology to be carried out.

U.K. Nuclear Reactor Research and Development

In a written answer in the House of Commons on November 5, the Parliamentary Secretary for Science, Mr. D. Freeth, stated that the Capenhurst Plant was not being closed down. Its output would be reduced gradually by the end of 1963 to the minimum level to keep it in production and available to meet any future increase in demand. Difficulties in the operation of the Dounreay breeder reactor experiment had been overcome and the reactor resumed operation at 30 MW (Heat) on July 26 and since October 14 had been supplying 3 MW of electricity to the national grid. It was intended as the next phase to run the reactor for some months at about 30 MW (Heat) to obtain information on fuel element behaviour. The Authority now has in hand the design and development of a prototype fast power reactor drawing on the experience at Dounreay.

Expenditure on Buildings and Plant for Scientific Research

In the House of Commons on November 5 the Chancellor of the Exchequer, Mr. R. Maudling, announced in the debate on the Address to the Throne that he proposed to raise the investment allowance on new plant and machinery and other assets from 20 to 30 per cent and on industrial buildings and other assets from 10 to 15 per cent. The cost of this change was estimated at some £8 million next year and about £50 million the following year. He also proposed that for new heavy capital plant and machinery the lowest actual annual rate of depreciation should be 15 per cent corresponding to a 12 per cent basic rate. The cost of this change was estimated at £15 million in the second year, rising to as much as £35 million a year. He also proposed that capital expenditure on buildings and plant for scientific research should in future be written off 100 per cent in the first year, as well as qualifying for the increased investment allowance of 30 per cent. The cost of this change was estimated at £4 million in the first full year.

The Building Research Station and the Ministry of Public Buildings and Works

In reply to a question in the House of Lords on November 7 regarding the functions of the newly appointed Director-General of Research and Development of the Ministry of Public Buildings and Works, Sir Donald Gibson, and whether this appointment would involve the removal of the Building Research Station from the responsibility of the Minister for Science, Lord Hailsham said first that he hoped that two principles would remain inviolate. First, research under Government auspices should be undertaken under the general supervision of scientists: this was the purpose of the Department of Scientific and Industrial Research and of the Research Council system. Secondly, the organization of research should be co-ordinated centrally, usually through one of the Research Councils. In spite of the importance he attached to these two principles, Lord Hailsham said that he did not deprecate research by executive departments provided these principles were accepted. The functions of the Director-General of Research and Development would be to co-ordinate and extend the activities of the various research and development groups throughout the Government service; to assume direct responsibility for the work of the development groups in the Ministry of Public Building and Works; to encourage and develop generally the use of new and rapid methods of construction; to standardize the use and production of building components to the greatest possible extent, and to secure the widespread dissemination of the best modern practices. The appointment did not involve the removal of the Building Research Station from the responsibility of the Minister for Science or of the Department of Scientific and Industrial Research. It was a necessary step in the assumption of responsibility by the Minister of Public Building and Works for co-ordinating the extensive work already proceeding within Government departments in the development and use of new, cheaper and speedier methods of construction. Almost half the total output of the construction industries was for public authorities. Sir Donald Gibson's functions would lie far more in the operational field than in that of pure research, although undoubtedly he would be greatly interested in research and would wish to stimulate and direct research along the most fruitful lines.

The National Research Council of Canada

Founded in 1916, the National Research Council of Canada now has an operating budget of about 42 million dollars. Some 14 million dollars are required for 'foundation' work—scholarships and research grants, in science, engineering and medicine—and the remainder is used to operate the laboratories. High standards are required of the 2,600 personnel, of whom 730 are scientists and engineers. About 690 of these are engaged in research, 360 having a Ph.D. degree and 330 having a Bachelor's or Master's degree. Approximately 250 are engineers. A detailed report of all the Divisions, including the Atlantic Regional Laboratory and the Prairie Regional Laboratory, gives considerable information about the contribution the Council is making in building up knowledge and the economy of Canada (*Canada. Review of the National Research Council, 1962*. Pp. 383. Ottawa: National Research Council, 1962).

Grants to Students in the United Kingdom

The important changes in grants to students operating from September 1, 1962, are detailed in Part 1 of a pamphlet issued as a short guide for students resident in England and Wales who are taking first degree or comparable courses (*Grants to Students—First Degree and Comparable Courses*. Pp. 8. London: Ministry of Education, 1962). Part 2 explains the contribution to be paid by students and parents. An appendix, which lists full-time or sandwich courses designated by the Ministry as comparable to first degree courses, also indicates where further information can be obtained.

Carnegie Grants for Field Work in Natural History

The Carnegie Trust has approved grants to five societies for field work projects. Assistance is being given to the Suffolk Naturalists' Society for population studies on noctule bats and to the Castleford and District Naturalists' Society for a study of a large hirundine roost. The Selborne and the Hampstead Scientific Societies are receiving grants for ecological surveys, and a grant has been approved to enable the Wharfedale Naturalists' Society to have a set of aerial photographs made in connexion with their survey of Ilkley Moor (*News for Naturalists*, 4, No. 1; July, 1962.)

University News :

Birmingham

The following appointments have been announced: *Lectureships*, Dr. J. F. Barrett (mechanical engineering); Dr. A. P. Brown (biochemistry); F. W. Darwin (zoology and comparative physiology); C. S. Dunn (highway and traffic engineering in the Department of Civil Engineering); Dr. B. P. Hughes (civil engineering); Dr. H. G. Klemperer (biochemistry); Dr. A. E. Pedler (chemistry); P. J. Reilly (civil engineering); Dr. A. E. Wright (geology). *Research fellowships*, K. I. Bartlett (engineering production); S. Brojdo (Associated Television Fellow in the Department of Electrical Engineering); R. M. Burstall (Kenward Memorial Fellow in the Department of Engineering Production); E. Carel (mathematical physics); B. T. Davies (engineering production); P. W. Graves (physical metallurgy); Dr. R. Hancock (biochemistry); A. A. Knight (engineering production); Dr. S. K. Mitra (physical metallurgy); J. C. Morris (electrical engineering); M. Richer (engineering production); L. F. Turner (Associated Television Fellow in the Department of Electrical Engineering); Dr. R. L. Cochrane (anatomy); Dr. B. Tallini (staff Fellow in nuclear physics); P. J. Waterton (staff Fellow in nuclear physics); M. Cordey-Hayes (nuclear physics); D. Smith (electron physics); H. F. Ross (neurocommunications); R. M. Norris (medicine).

The title of reader in chemical engineering has been conferred on Dr. R. Long, senior lecturer in the Department of Chemical Engineering. Titles of University Research Fellow have been conferred on O. C. Schauer (geology) and A. H. Barth (electrical engineering).

Cardiff

Dr. K. S. Dodgson, senior professor in the Department of Biochemistry in the University College of South Wales and Monmouthshire, has been appointed to the chair of biochemistry at the College in succession to Prof. J. Pryde, as from October 1, 1963.

London

Dr. J. T. Eayrs, professor of neuro-endocrinology in the University of Birmingham, has been appointed to the Fitzmary chair of physiology tenable at the Institute of Psychiatry. Dr. John Gloster, formerly a member of the scientific staff of the Medical Research Council, Ophthalmological Research Unit, has been appointed to the readership in experimental ophthalmology tenable at the Institute of Ophthalmology. Dr. G. S. Nelson, parasitologist in the Kenya Medical Department, has been appointed to the readership in medical parasitology tenable at the London School of Hygiene and Tropical Medicine.

Sheffield

R. Barer, at present University demonstrator in human anatomy in the University of Oxford, has been appointed to the Arthur Jackson chair of human biology and anatomy. Dr. G. E. Bacon, deputy chief scientific officer, Atomic Energy Research Establishment, Harwell, has been appointed to the chair of physics and headship of the Department of Physics as from October 1963. (It has been decided to experiment with a system in which the headship of the Department of Physics will be held in turn for a period of three years by each of the two professors concerned.) Dr. M. G. H. Wallbridge has been appointed as a lecturer in chemistry.

Announcements

Sir Hans Krebs, Whitley professor of biochemistry in the University of Oxford, has been elected an honorary member of the Belgian Royal Academy of Medicine.

The third Joint Health Physics symposium organized on behalf of the Joint Health Physics Committee of the British Institute of Radiology will be held at St. Bartholomew's Medical College, Charterhouse Square, London, E.C.1, on January 25. The subject will be "Metabolism of Biologically Important Radionuclides". Further information can be obtained from the General Secretary, the British Institute of Radiology, 32 Welbeck Street, London, W.1.

"Viruses, Nucleic Acids and Cancer" is the title of the seventeenth annual symposium on Fundamental Cancer Research which will be held at the M. D. Anderson Hospital, University of Texas, during February 20–22. The symposium is being organized by the Hospital in conjunction with the U.S. National Cancer Institute and the Texas Division of the American Cancer Society. Further information can be obtained from the chairman of the symposium, Prof. L. Dmochowski, Department of Biology, the University of Texas M. D. Anderson Hospital and Tumor Institute, Texas Medical Center, Houston 25, Texas.

A symposium on "Recent Developments in the Chemistry of Genetic Processes" will be held at the Bradford Institute of Technology on February 9. The symposium is being organized by the Bradford Chemical Society and the Department of Chemical Technology of the Bradford Institute of Technology in conjunction with the Yorkshire Council for Further Education. The programme will include the following papers: "Recent Developments in the Chemistry of Nucleic Acids", by Dr. R. Markham (Agricultural Research Council); "Protein Synthesis in Mammalian Tissues", by Dr. H. N. Munro (University of Glasgow); "Some Aspects of the Action of Chemical Mutagens", by Dr. D. M. Brown (University of Cambridge); "Biochemical Aspects of Genetics", by Dr. J. R. S. Fincham (John Innes Institute). Further information can be obtained from Dr. R. P. Sheldon, Department of Chemical Technology, Bradford Institute of Technology, Great Horton Road, Bradford 7.

Erratum. The sentence beginning on line 19 of the second paragraph of the article entitled "Coordination Compounds as Resolving Agents", by the late F. P. Dwyer and Dr. B. Halpern, which appeared on p. 270 of the October 20 issue of *Nature*, should read: "The specific rotation $[\alpha]_D$ was $-35°$ (0·125 g in 1 N sodium hydroxide, 2 dm. tube)".

CLINICAL TESTING OF NEW DRUGS IN THE UNITED STATES

REGULATIONS strengthening control over the testing of new drugs in clinical trials have been approved by the U.S. Department of Health, Education and Welfare. The new regulations would require: that the Food and Drug Administration be given the full details about the distribution of drugs for investigation ; that clinical investigations be based on adequate pre-clinical studies to assure safety; and that the clinical investigations themselves be properly planned, executed by qualified investigators, and that the Food and Drug Administration authority be kept fully informed during the progress of the investigations.

The present regulations require that drugs used in clinical trials be labelled for "investigational use" only and that manufacturers keep records of distribution. The regulations also require that investigators have adequate facilities, and that names of investigators be made available to the Food and Drug Administration on request.

Existing regulations, however, do not require either an initial notice to the Food and Drug Administration of a clinical trial of a new drug or subsequent reports on such use. Now, once a clinical investigation has been undertaken, if a substantial doubt developed as to the safety of the drug, the Food and Drug Administration and all investigators using the drug would be notified immediately. If necessary, the trial would be halted by the Administration. Similarly, if a plan proved to be inadequate to assure safety, or if the plan as presented was not being followed, the Administration could require corrective action and would, if necessary, terminate the work.

In notifying the Food and Drug Administration of his intention to begin a clinical investigation with a new drug, a manufacturer would be required to provide information concerning all the pre-clinical investigations, including experimental trials which had been undertaken with animals, to show that it is reasonably safe to test the drug on human patients. Where the clinical investigation involves use on infants or pregnant women, special assurances of safety for such use would be required; copies of the complete information about the pre-clinical investigation and experience with the drug which will be supplied to each investigator, including all that is known about the relevant side effects and precautions suggested by the pre-clinical data; and the names and a summary of the training and experience of each person who will participate in the investigations and an outline of what is planned in the clinical trials, how long they will take, how many patients will be involved, and when progress reports will be made.

Once an investigation was undertaken, the sponsors would be required to maintain complete records covering the distribution of the drug being investigated, and monitor the progress of the investigation.

Each investigator in the clinical trial would be required to supply the sponsor with a full statement of his education and experience, a description of the hospital, institutional and laboratory facilities available to him, and an outline of the plan that he intends to follow. He must fully inform himself about all the pre-clinical investigations before giving the drug to any patient, maintain complete records of his disposition of the drug and case-histories of the patients to whom it is administered, and furnish adequate reports to the sponsor promptly after the completion of the clinical trials. These records must be open to inspection by the Food and Drug Administration on request.

The proposed regulations were published with an invitation for all interested persons to comment within 60 days. Copies of the full regulations are available from the Commissioner of Food and Drugs, U.S. Department of Health, Education and Welfare, Washington 25, D.C.

LIBRARIES AND PUBLIC SERVICES

THE annual conference of the Library Association at Llandudno, September 25–28, was the first annual conference to be held since the Association was transformed into a purely professional body, but although the president, Mr. W. B. Paton, considered the implications of this change in his presidential address, "The Profession of Librarianship", the proceedings otherwise presented fewer features of general scientific interest than usual.

Mr. Paton boldly challenged the profession to tackle its objectives with unity and courage, particularly the problems involved in relating public libraries to the library service of the country as a whole, and attributed the failure of the Roberts Committee to face that problem to the negligence of the Library Association itself. His exposition of the professional ideal contains much that is to the point for any professional man or woman, whether in a particular section of the profession of librarianship or in any other profession. So, too, Mr. A. H. Bill's discussion on September 26 of the problems of the library in the community indicates ways in which readers themselves might co-operate in the development of a service which meets far more adequately and effectively the needs of to-day. However, in the first instance, he urges librarians themselves to discard the erroneous ideas that the public library is a collection of books and provides a service for various types of readers and to seek instead to develop the layout and arrangement of our libraries in accordance with the three-fold conception of their function and purpose. First, there is the provision of a community information service; secondly, that they act as a collection of information in various forms which has to be gathered, organized and fully exploited to be made fully and speedily available to every user; and thirdly, that the service given is to individuals, not to groups or types of readers. He believes that the public library could be a most potent means of achieving Dr. J. R. Oppenheimer's idea: "to keep our minds open and to keep them deep, to keep our sense of beauty and our ability to make it".

Mr. A. Duggan's stimulating annual lecture, also on September 26, "Personal Experience and the

Interpretation of History", aptly illustrates the possibilities in this direction and also has some implications for the writing of industrial and scientific history that the scientist or technologist might ponder. Mr. D. D. Haslam, when discussing on September 27 the problems of library staffing, covered university and Government libraries as well as those of commerce and industry, the technical colleges and the public libraries, and presented a balanced picture of trends and difficulties and their implications which is of wide interest. The planning of central libraries was considered by Mr. F. M. Gardner on September 25 in a paper of interest to industry and commerce as well as to public libraries, while on September 26 Mr. P. H. Sewell examined generally present-day thought on library co-operation though without considering the technical implications of the Roberts report. Miss C. Jones, on September 27, under the title "From Book-Box to Telex: Mechanization for County Libraries", discussed some of the developments and opportunities which mechanization had brought to the county library service. Other papers presented at the conference were concerned with libraries and youth, children's reading and aspects of library service in hospitals.

FORCES IN COLLOIDAL SYSTEMS

An informal discussion of the Faraday Society on the nature of forces in colloidal systems was held in the Chemistry Department of the University of Nottingham during September 20–21, by kind permission of the Vice-Chancellor. The meeting was attended by 108 people, 69 of whom came from industrial organizations and 39 from educational institutions.

Colloidal systems are very diverse in character, and the early research on colloids was essentially based on phenomenology. It has therefore become increasingly important, in order to understand systematically the behaviour of such a wide range of systems, to obtain a deeper understanding of the fundamental forces which act between particles, or molecules, of colloidal dimensions. The forces have the same origin as those acting between simple ions and molecules but in colloidal systems the situation becomes more complicated since the 'ion' may consist of a particle with a number of charges on the surface, for example, a micro-crystal of silver iodide. or an assembly of soap ions as in a micelle. Both repulsive and attractive forces have to be averaged over a surface, and in recent years theoretical work has been devoted to obtaining equations which enable the variation of the force to be predicted over distances of the order of those separating colloid particles. The equations require experimental verification of their validity, and in recent years work on the stability of dispersions, on the structure of soap micelles, and on the stability and structure of thin soap films has yielded some measure of the relative contribution of electrical, attractive and solvation forces. This trend was clearly illustrated during the course of the discussion.

On September 20, the afternoon session was entitled "Stability of Dispersions in Aqueous and Non-aqueous Media". After an address of welcome by Prof. D. D. Eley, the chair was taken by Sir Eric Rideal, who, in his introductory remarks, stressed the importance of colloids as a field of study and the need for deeper understanding of the fundamentals of the subject. A great deal of work was still required to elucidate the part played by the solvent both in aqueous and non-aqueous media.

The first paper, by Dr. J. A. Kitchener and Mr. F. Z. Saleeb (Imperial College of Science and Technology), reported work on the adsorption of 'Aerosol *OT*' by a graphitized carbon black in aqueous media. The adsorption isotherms showed saturation adsorption corresponding to a close-packed, vertically oriented, monolayer of 'Aerosol *OT*' ions having their sulphonate head groups exposed to the liquid. Complementary measurements of zeta potential, surface conductance and the negative adsorption of co-ions were also made. Results suggested that the majority of the counter-ions were located in the Stern plane and that the plane of shear in the electrokinetic experiments was close to the plane of the head groups of the adsorbed 'Aerosol *OT*' ions.

Mr. P. Dawson and Dr. D. A. Haydon (University of Cambridge) presented work on the adsorption of a series of *n*-alkyl carboxylic acids by titanium dioxide suspensions in benzene. The dispersions used were of small particle size (radius *c.* 25 Å) and it was found that the stability of the dispersion increased as the length of the alkyl chain was increased. It was suggested, therefore, that stabilization did not occur until the chains were sufficiently long for steric hindrance to occur between the adsorbed layers. An exception was found in the case of acetic acid, which also appeared to stabilize the system; it seemed improbable, however, that in this case stabilization could arise from steric hindrance.

An account of adsorption on to 'Graphon', from binary liquid mixtures of monoalkyl benzenes and *n*-heptane, was given by Dr. G. D. Parfitt and Mr. E. Willis (University of Nottingham). The apparent isotherms changed in nature as the length of the alkyl side-chain increased, indicating an increasing preferential adsorption of the alkyl benzene. The adsorption isotherms calculated for the individual components suggested a saturation monomolecular layer of alkyl benzene with the molecules lying flat on the surface. Complementary measurements of stability were made on dilute dispersions of 'Graphon', and it was found that the stability increased, with the proportion of alkyl benzene in the mixture and the length of the alkyl chain. The van der Waals attraction constant calculated for this system, with due allowance for the thickness of the adsorbed layer. appeared to be too large to account for the stability observed experimentally.

Drs. K. G. Mathai and R. H. Ottewill (University of Cambridge) presented the results of work on the stabilization of aqueous inorganic dispersions by non-ionic detergents. The rate of flocculation of sols by bivalent and trivalent ions was measured in the presence of various concentrations of non-ionic detergents. The latter were polyoxyethylene glycol monoalkyl ethers, the alkyl chain length of which was varied from eight carbon atoms to sixteen; the length of the polyoxyethylene glycol chain was maintained constant at six units. As the concentration of non-ionic detergent was increased the concentration of inorganic salt required to produce flocculation also increased. Above the critical micelle concentration of the detergent, however, a large increase in stability of the sol occurred. Below the critical micelle concentration the increase in stability was attributed to the increase in hydration of the sol particles caused by adsorption of a thin layer of detergent molecules. The large increase in stability observed above the critical micelle concentration was considered to be due to the fact that the adsorbed molecules prevented the particles from approaching sufficiently closely to enter the primary minimum.

On September 21, the session was entitled "Micellization", and the chair was taken by Prof. D. D. Eley. The first paper in this session, by Dr. A. S. C. Lawrence and Messrs. R. Aveyard and J. T. Pearson (University of Sheffield), presented the results of studies on micellization using calorimetry. Results were presented for micellization and co-micellization (the case of a polar micelle incorporating amphiphilic molecules) and also for the effects of salt concentration on these phenomena. The heats of solution of a series of *n*-alcohols in water and in soap-water mixtures were discussed in terms of the heats of hydration of the hydrocarbon chain and the polar or ionic head group. The contribution to the energy terms due to increased unbinding of counter-ions in the co-micellization process was discussed, and the calorimetric measurements were supported by measurements of conductance, *p*H and sodium ion activity in these systems; the latter measurements involved the use of a sodium responsive glass electrode.

Mr. J. Clifford and Dr. B. A. Pethica (Unilever, Port Sunlight) reported the results of measurements on the self-diffusion of micelles of sodium dodecyl sulphate (dye labelled) and on the self-diffusion of sodium ions (radio-tracer labelled) in the presence of these micelles. The mechanism of binding counter-ions to the micelle by means of electrostatic forces was discussed. The results of some preliminary studies on micelles using nuclear magnetic resonance were also presented. A change in spin lattice relaxation time of the water protons was found in the presence of the micelles, suggesting that water had been immobilized near the micelle surface. The spin lattice relaxation time of the protons in the CH$_2$ groups in the interior of the micelles was approximately ten times shorter than the relaxation time of CH$_2$ groups in liquid hydrocarbons. This suggested that the alkyl chains in the interior of the micelle were under compression.

The structure and stability of black foam films were discussed by Dr. J. F. Goodman (Procter and Gamble, Ltd., Newcastle upon Tyne). Experiments were described in which simultaneous measurements were made of the total film thickness, using an optical method, and of the water content using infra-red spectroscopy. The detergent content of the film was determined by radio-tracer experiments. It was shown that the black film (50–100 Å thick) has a simple lamellar structure in which two monolayers of surface-active molecules are spread on a thin aqueous core. In mixed cationic–anionic surface-active systems it was found that the ratio of anionic to cationic material in the film was always 1 : 1. irrespective of the ratio in the bulk liquid. Under these conditions it appeared unlikely that the film could be stabilized by electrostatic repulsion between opposing monolayers of soap ions. The factors influencing the stability of the thin films were discussed in terms of the evaporative equilibrium of the volatile film component. It was suggested that the stability of a black film could be maintained by an excess of solute, relative to the bulk solution, in the aqueous film core.

Prof. B. Stuke (University of Munich, Germany) discussed the thermodynamics of micellar systems. In the first part of the paper a discussion was given of the respective merits of using the law of mass action to describe micellization and of considering the micelle as a separate phase. It was concluded that thermodynamically the law of mass action gives the sound approach, the phase approach being only an approximation. Starting from a model for the process of micelle formation at interfaces the second part of the paper was concerned with the influence of micelles on the stabilization of thin films.

GEOLOGY AND GEOPHYSICS IN THE U.S.S.R.

THE following are abstracts of geological topics that appeared in the Soviet journal *Priroda* during 1962; for convenience they are arranged under general headings (in italics).

Tunguska 'meteorite'. The so-called Tunguska 'meteorite', which fell in Siberia (60° 55′ N., 101° 57′ W.) on June 30, 1908, is once more in the news as the results of the 1961 expedition are made known. This expedition remapped the directions of the fallen trees over an area of 2,000 km^2, and located and investigated the nature of the so-called 'impact' craters and the composition of spherical granules extracted from the ground. According to the conclusions of V. G. Fesenkov (*Priroda*, 8, 24; 1962) and K. P. Florensky and I. T. Zotkin (*Priroda*, 8, 31; 1962), the impact was not that of a meteorite but of a comet which struck the Earth at a glancing angle and exploded. However, according to N. I. Piavchenko (*Priroda*, 8, 39; 1962) the observed cavities in the peat bog are not due to impact but to ordinary processes occurring in regions of permafrost.

Meteorite crater in Sayan Range. According to M. V. Voroshilov (*Priroda*, 3, 107; 1962) an elliptical hollow, rimmed by a 'bulge' and filled by a lake, some 150–400 m in diameter, situated on the eastern foothills of the Western Sayan Range, represents a meteorite crater. The author suggests that the meteorite responsible for this hollow fell about 150 years ago.

Biogeochemistry. Recent research in biogeochemistry carried out in the U.S.S.R., including the part played by micro-elements in animal nutrition, rational compensatory feeding and biogeochemical provinces and zones, is discussed by V. V. Kovalsky in the June issue of *Priroda* (6, 3; 1962).

Arctic regions. A brief review of recent expeditions to the Soviet Arctic has been made by B. A. Kremer (*Priroda*, 6, 61; 1962), while an up-to-date general account of the geology of the Arctic region is provided by Y. M. Pushcharovsky (*Priroda*, 4, 35; 1962). The latter article contains a reduced version of a tectonic map of this region compiled by the members of the Institute of Geology of the Arctic. In the descriptive part, the author provides a brief geological–tectonic account based on recent publications in the U.S.S.R., Finland, Norway, Greenland and Canada.

Elbrus. According to J. Y. Panteleev and Y. P. Masurenkov (*Priroda*, 5, 61; 1962), Elbrus (5,630 m) —the highest mountain in Europe—is not an extinct volcano, but only dormant. This is testified by its extensive fumarolic field giving out numerous steam and gas emanations under its ice cap. The principal gases emitted are carbon dioxide, chlorine, fluorine and boron compounds. Some emanations are 200°–300° C at their source.

Geothermy. The first All-Union Conference on the problems of geothermy was held in Moscow during March 1–6, 1956, and the transactions, edited by V. I. Vlodavets and others, were published in the form of two volumes entitled "Problems of Geothermy and Practical Utilization of the Heat of the Earth" (*Pub. Acad. Sci. U.S.S.R.*, 1; 1959; 2; 1961). The first volume contains 22 articles, including contributions by I. D. Dergunov, E. A. Lyubimova (both dealing with the thermal regime and history of the Earth), B. N. Dostovalov (the thermodynamic study of the Earth), V. I. Vlodavets (the hydrothermal regions of Italy and New Zealand) and A. M. Zhirmunsky (problems of geothermo-energetics). These volumes also contain sections dealing with problems of regional geothermy and methods of geothermal studies. The second volume contains 26 articles dealing with problems of hydrogeothermy and detailed regional investigations of hydrothermal regions of the Soviet Union. One of the articles, by S. A. Dzhamalov, deals with the thermal waters in Daghestan. In a more popular article (*Priroda*, 6, 74; 1961) the same author describes the progress made in the utilization of thermal waters in Makhach-Kala, the capital of Daghestan. This town has already six active boreholes supplying 4,000 m³ of water at 55°–68° C per 24 h. This water is used for heating and supply of hot water for domestic and industrial needs. A new borehole is projected to supply 2,000 m³ of water up to 160° C per 24 h to a geothermal power station.

Geocryology. Geocryology, or the science of permafrost, as studied in a special Institute of the Academy of Science, U.S.S.R., is of great importance due to its wide application in the Soviet Union, especially in connexion with buildings, canals and roads. A brief account of permafrost in the Union, illustrated by a new geocryological map, has been provided by I. A. Nekrasov (*Priroda*, 2, 19; 1962).

Slow movements of the Earth's crust. In 1960, at the seventh general assembly of the International Union of Geodesy and Geophysics held in Helsinki, a special commission for the study of micropulsation and slow movements of the Earth's crust was established, under the chairmanship of Y. A. Meshcheryakov. Various aspects of this work are presented by L. E. Setunskaya (*Priroda*, 3, 27; 1962) and V. F. Bonchkovsky (*Priroda*, 7, 48; 1962), while V. V. Lamakin (*Priroda*, 7, 53; 1962) discusses the slow movements of the Earth's crust in the region of Lake Baikal.

Geochronology. Much work is being carried out in the Soviet Union on geochronology. Recent research in this field is summed up by I. E. Starik and E. V. Sobotovich (*Priroda*, 5, 75; 1962), who provide a summary date of absolute age for the geological periods. They also conclude that the ancient parent matter of meteorites is 4,500 million years old, while the minimum age of the Earth is of the order of 3,500 million years. In another article, V. V. Cherdyntzev (*Priroda*, 6, 42; 1962) gives an account of the origin and development of the potassium-argon method of geochronology. This method was originally demonstrated by V. G. Khlopin and E. K. Gerling and rapidly developed by numerous research workers, among whom was prominent the group led by A. A. Polkanov in the Laboratory for the Study of the Precambrian at Leningrad. At the present time, more than twenty laboratories carrying out 'potassium-argon' measurements for dating are functioning in the U.S.S.R.

THE ATOMIC ENERGY COMMISSION OF JAPAN

THE fifth annual report of the Atomic Energy Commission of Japan, which was established in 1956, is the first to be published in English*. It describes in some detail the aims and activities of the Commission and its subsidiary organizations, the Japan Atomic Energy Research Institute (JAERI), the Atomic Fuel Corporation (AFC) and the National Institute of Radiological Sciences (NIRS). The total number of employees of these organizations now exceeds 1,900. About 60 per cent of the Governmental budget (about 8,000 million yen) for atomic energy is allocated to JAERI. The Research Institute has three reactors: *JRR*-1, which has continued normal operation during the year under review; *JRR*-2 which reached criticality during October 1960 and which is used by private companies and universities; and *JRR*-3, which was due to be completed during September 1961 and to become critical by March 1962. The Japan power demonstration reactor (*JPDR*) is being constructed by the General Electric Co., United States, and the construction of *JRR*-4 (shielding research reactor) by JAERI was to be completed by the end of the fiscal year 1961. Reactors are under construction also at Rikkyo University, the Musashi Institute of Technology and Kinki University. Among the private concerns, both Hitachi, Ltd., and Tokyo Shibaura Co., Ltd., have decided to build training reactors and to gain atomic energy experience under Government subsidy. During August 1960, the JAERI concluded a contract for the purchase of a *BWR*-type power demonstration reactor.

On February 8, 1961, the Commission announced a new long-range programme of nuclear power generation. On the assumption that nuclear power will become competitive with thermal power in cost in about 1970, it is estimated that new power-generating capacity of 36,000 MW will be required between 1961 and 1970, and 48,000 MW between 1971 and 1980, and that of this 1,000 MW and 6,000–8,000 MW will be provided by nuclear power plants during the respective decades. Private companies are expected to install the nuclear power stations, which will be of the light-water-cooled and gas-cooled types, and possibly in later years the organic cooled type.

---

* Japan, Atomic Energy Commission. Fifth Annual Report, 1960–61. Pp. iv+167. (Tokyo: Atomic Energy Bureau, Science and Technology Agency, 1962.)

A centre for nuclear research and development is being completed at Tokai-mura, and an institute for plasma physics is being set up on the Higashi-yama campus of Nagoya University. The institute will consist of seven research divisions covering theoretical studies and high-temperature generation experiments. An investigation of the required high-voltage supply and of the pinch effect was initiated in 1957 at Osaka University and since then plasma physics research has been carried out at Tohoku University, Tokyo University of Education, Tokyo University, Nagoya University and Kyoto University. At present there are approximately sixteen different forms of apparatus planned or under construction by twelve plasma physics research groups in Japan.

In the chapter of the annual report dealing with uses of radiation it is stated that most of the radioisotopes used in Japan are imported. During 1960 a total of 55,000 curies were imported, consisting mainly of cobalt-60, phosphorus-32 and iodine-131. By the end of March 1961, 867 establishments, representing medical organizations, private firms and universities and research institutes, in approximately equal numbers, were using radioisotopes. JAERI is preparing for full-scale production of radioisotopes in order to fulfil the future domestic requirements. The first six isotopes to be produced will be sodium-24, phosphorus-32, sulphur-35, potassium-42 and gold-198.

Other chapters of the report deal with nuclear equipment and materials; radioactivity surveys; treatment of radioactive waste; regulations and radiation protection; and training of scientists and engineers. It is considered that 11,000–13,000 scientists and engineers in nuclear energy will be required in the next ten years and it will be necessary to train and educate some 8,000 in those ten years. At present, the possible number to be trained each year is 150–200 at universities, about 200 at JAERI and NIRS, and 90 at institutions outside Japan.

S. Weintroub

GASEOUS OPTICAL MASERS

Bell Telephone Laboratories Inc. have issued a brochure describing recent work at Murray Hill, New Jersey, on the gaseous optical maser. The Bell Laboratories are the most active single organization in this field, and have recently extended the range of wave-lengths available from the maser. The first type of gas discharge optical maser, initially operated by Javan, Bennett and Herriott in February 1961, used a helium–neon mixture and produced an output at 1·15μ. Since then, population inversion sufficient to support maser oscillation has been obtained in gas discharges in pure inert gases (helium, neon, argon, krypton and xenon) providing a total of fourteen different wave-lengths in the range 1·618–2·189μ. Inversion has also been achieved between two levels of the oxygen atom by dissociating molecular oxygen in collisions with an inert gas atom, either argon or neon, in a metastable state, using a discharge in a mixture of oxygen and the inert gas. The maser output in this case is at 8446 Å. The shortest wave-length, and consequently the most useful for applications involving high-efficiency photoelectric detection, lies in the visible at 6328 Å, and has been obtained from a helium–neon maser with mirrors having a high reflectivity at this wave-length.

Power outputs of these new masers are in the range from a fraction of 1 mW to 10 mW. The experimental work has been done with masers using external confocal mirrors and a discharge tube having end windows at the Brewster angle to the emergent beam, thus eliminating, for the appropriate plane of polarization, reflexion and consequent energy loss at the windows.

The information in the Bell Telephone Laboratories brochure is an indication of the great effort which is being put into the development of the gaseous maser, which is already being applied to a number of research problems and may, in the future, find uses in the communications field.

J. H. Sanders

EFFECT OF MOISTURE MOVEMENT OF NATURAL AGGREGATE ON CONCRETE

Some years ago investigations of concrete failure, thought to be due to the chemical reactivity of certain rock-types involved with the cement during hydration, were carried out in the United States and later in the United Kingdom. Arising from this, certain rock-types, for example, some dolerites, especially those containing the chlorite mineral chlorophaeite, became suspect. Experimental work was based largely on chemical and petrological studies to determine potential reactivity with alkalis released during hydration of Portland cement in concrete involving aggregates dominated by supposedly unstable components. Methods of determination of such components were tentatively laid down by the American Society for Testing Materials (*Proc.*, 48, 1948; and *Standards*, 1952), and in the United Kingdom F. E. Jones has discussed the subject in some detail (*National Building Research Studies*, Nos. 14, 15, 16; 1952).

The evidence from this experimental work cannot be considered as conclusive; in fact, some of it is so conflicting as to raise grave doubts on the alleged chemical vulnerability of certain dolerite aggregates, including natural gravels containing these rock-pebbles, or others loaded with acid volcanic types, also suspect. There is at present what appears to be a more convincing explanation of this type of concrete failure. In a paper by L. C. Snowdon and A. G. Edwards, entitled "The Moisture Movement of Natural Aggregate and its Effect on Concrete" (*Concrete Research*, 14, 109; 1962), is described the work of the Scottish Laboratory of the Building Research Station on the failure of pre-cast concrete products in which certain crushed dolerite aggregates had been used. It is pointed out that in Scotland dolerite aggregate is extensively used in concrete.

The interest of the Department concerned ". . . became focused on its performance in 1952 when very severe cracking developed in concrete specimens after a single winter's exposure on the exposure site at Thorntonhall, near Glasgow. It was later found that the dolerite rock itself exhibited large dimensional changes in water content". Volume changes due to chemical reaction were investigated but not substantiated. Since dimensional changes on wetting and drying of the rock itself occurred, a study was made of the expansion and contraction caused by moisture in various Scottish dolerites and concretes made from them. The experiments were extended to other rock-types as well as natural sands and gravels used as aggregates for concrete. The arguments in this paper are convincing and establish that many natural crushed rock and gravel aggregates undergo changes of volume as they take up water, thus influencing both the shrinkage and the durability of the concrete in which they are incorporated. H. B. MILNER

DEMOGRAPHY OF MAURITIUS

THREE hundred and fifty years ago the island of Mauritius was uninhabited by man. The only creatures there were some indigenous reptiles and birds, and a few domestic animals left by passing sailors. To-day, the dodo is extinct, but within the island's narrow confines lives one of the most rapidly growing human populations in the world.

Mauritius is a hurricane-battered island in the Indian Ocean. It is about 500 miles east of the island of Madagascar, more than twice that distance from the south-eastern coast of Africa, and 200 miles north of the Tropic of Capricorn. In a land area of 720 sq. miles, there are 990 Mauritians for every square mile, an immense burden for the island's meagre natural resources and limited facilities. Until 1946, the rate of natural increase was low. Immigration accounted for almost half the total growth. In 1946 there were 428,000 people on the island. Recently, a dramatic shift in the survival pattern upset the two-centuries-old balance between births and deaths which had held the population in check. In just five years, the death-rate dropped from 36 to 14 and the birth-rate rose from 38 to 50 per thousand of the population per year.

It is estimated that, in 1961, there were 656,000 people on the island, an increase of more than 50 per cent in only 15 years. During the period, natural increase averaged 2·9 per cent a year, one of the highest rates in the world. Immigration had not been an important feature in population growth. By 1961 the Mauritian death-rate was 10, lower than that of the highly urban-industrial United Kingdom. The Mauritial birth-rate had receded to 40, a rate typical of those found in less-developed countries. Should the phenomenally rapid multiplication of people continue, Mauritius would have a population of more than two million in the year 2,000—a three-fold increase in only 39 years.

One of the most serious consequences of this over-rapid growth is a population with a bottom-heavy age structure which adds to Mauritius's economic difficulties. To-day, 44 per cent of the population is under 15 and another 3 per cent is 65 years or older. If the rate of population growth is maintained, the increase in the economically dependent age-groups could strangle the economy. In less than 25 years, the number of children under 15 alone would be larger than the entire population in 1960.

This island is one of the few less-developed countries with a tradition of reliable vital statistics, introduced by the British. Thus, Mauritius serves as an almost perfect small-scale example of how too-rapid population growth can depress living-levels when the resource base is meagre and limited.

There seems to be but one ray of hope in Mauritius. Although the birth-rate is still alarmingly high, it has declined from its record peak of 50 in 1950 to 40 in 1961. The way in which the rising population of Mauritius may be controlled has been described by Robert C. Cook, editor of *Population Bulletin**.

* Population Reference Bureau. *Population Bulletin*, 18 No 5, August 1962: *The Story of Mauritius—From the Dodo to the Stork*. Pp 93–116 (Washington, D.C: Population Reference Bureau Inc, 1962.) 50 cents.

LACK OF ACTIVATION OF PHOSPHORYLASE BY ADRENALINE DURING ITS PHYSIOLOGICAL EFFECT ON INTESTINAL SMOOTH MUSCLE

By Prof. E. BUEDING
Department of Pathobiology, Johns Hopkins University, Baltimore, Maryland

Dr. E. BÜLBRING, F.R.S., and Dr. H. KURIYAMA
Department of Pharmacology, University of Oxford

AND

Dr. G. GERCKEN
Physiologisches Institut, Universität Köln

AN activation of phosphorylase by adrenaline has been observed in liver, skeletal muscle and heart muscle *in vitro* and *in vivo*[1]. When conventional experimental procedures were used, similar results were obtained from isolated intestinal smooth muscle preparations from the taenia coli of the guinea pig[2]. An improved technique was used for the experiments to be described in this communication, and the results show that an activation of phosphorylase does not occur in the tissue while the physiological effect takes place, and that earlier results[2,3] must be ascribed to a conversion of phosphorylase *b* to phosphorylase *a* during the period which elapsed between the removal of the tissue from the adrenaline-containing medium and the assay of enzymatic activity. As these observations are limited to a single type of smooth muscle, they do not rule out the possibility that activation of phosphorylase has a relationship to the physiological actions of adrenaline in other tissues. However, recent observations of Mayer, Cotten and Moran[4] have also indicated a lack of correlation between phosphorylase activation and the positive inotropic effect of adrenaline on the myocardium.

Phosphorylase activity was measured by the determination of glucose-1-phosphate produced from glycogen in the presence of inorganic phosphate. Conversions of phosphorylase *a* to *b* and of *b* to *a* were inhibited by the addition of sodium fluoride and of ethylenediamine tetraacetic acid, respectively. The possibility of these interconversions was minimized further by carrying out the assays at a 1,200-fold dilution of the tissue constituents, a procedure which reduced the final concentration of endogenous AMP to less than 2×10^{-7} molar. Activation of taenia coli phosphorylase *b* under these conditions was not observable below an AMP concentration of 1×10^{-5} M.

The tissue was homogenized at 0° with 100 vol. of a solution containing 0·02 M citrate buffer (*p*H 6·7) 0·001 M EDTA, 0·01 M sodium fluoride and 0·3 per cent serum albumin. Immediately thereafter 0·05 ml. of the homogenate were incubated in a centrifuge tube for 30 min at 37° C in a total volume of 0·6 ml. of a solution which had the following constitution: 0·5 per cent glycogen, 0·05 molar potassium phosphate buffer (*p*H 7·5), 0·01 M sodium fluoride, 0·001 M EDTA and 0·3 per cent serum albumin. Another 0·05 ml. of the homogenate was incubated in the same reaction mixture containing, in addition, 5-adenylic acid (AMP) in a final concentration of 1×10^{-3} M. At the end of the incubation period, 0·09 ml. of N hydrochloric acid were added. The tube was placed in an ice bath and 0·09 ml. of N potassium hydroxide and 0·23 ml. of a solution containing 0·2 M imidazole buffer (*p*H 7·5) (ref. 5) and 0·005 M magnesium chloride were added. The mixture was centrifuged at 8,000*g* and 0° C for 30 min. Glucose-1-phosphate was determined spectrophotometrically in an aliquot of the supernatant solution by the use of crystalline phosphoglucomutase[6] as described elsewhere[7]. The amount of glucose-1-phosphate formed in the absence of AMP was a measure of phosphorylase *a* activity, while total phosphorylase (*a* + *b*) activity was equivalent to the formation of glucose-1-phosphate in the presence of AMP.

Weighed pieces of taenia coli were suspended either isometrically (ratio $\frac{\text{wet weight (mg)}}{\text{length (mm)}}$: 0·65–0·8) or isotonically (initial tension, 1–3 gm) in 120 ml. of a modified Krebs solution[8] at 37° ± 0·5° C and gassed with oxygen containing 3 per cent carbon dioxide. After a period of 1–2 h, control samples were removed for assay, and adrenaline was added to the bath medium to yield a final concentration of 5×10^{-7} M. Tension recordings with the aid of spring balances[8] revealed that, without exception, addition of the hormone produced a decrease in tension within 5–10 sec. The tissue samples were removed for assay 5 sec–2 min after addition of the hormone. The results are shown in Table 1.

Table 1. PHOSPHORYLASE *a* ACTIVITY (IN PER CENT OF TOTAL PHOSPHORYLASE ACTIVITY) OF TAENIA COLI BEFORE AND AFTER EXPOSURE TO ADRENALINE (5×10^{-7} MOLAR)

Group	(*a*) Assayed at once			(*b*) Assayed after drawing or rubbing tissue on dry glass surface		
	No. of samples	Limits	Average	No. of samples	Limits	Average
Control	21	0–3·8	1·6	17	1·4–4·6	3·1
Adrenaline	46	0–4·1	1·6	21	5·1–11·4	8·3

In series (*a*), 27 out of the 46 samples were taken 5–15 sec after addition of adrenaline, that is, as soon as maximal relaxation of the muscle had occurred. In the control samples, phosphorylase *a* activity of taenia coli was minimal and was not increased by adrenaline (Table 1, series *a*). These results were obtained consistently if the tissue was placed immediately in the homogenizing medium and homogenized at once after removal from the adrenaline-containing bath medium.

In series (*b*), on the other hand, the phosphorylase *a* activity of the controls was higher and it was significantly increased by adrenaline. In this series the muscle samples were first dried by drawing them repeatedly over a glass plate for 5–8 sec, or they were placed on the upper dry part of the inner wall of the homogenizer and then pushed down along the wall into the homogenizing fluid. In a previous study[3], when the tissues were dried in this manner for the purpose of weighing, an increase in phosphorylase *a* occurred with adrenaline 5×10^{-7} M, but not at a 20-times lower concentration. When the tissue was cut in an ice bath prior to the assay, phosphorylase activation was observed also with 2×10^{-8} M adrenaline[2]. When the muscle was handled in this way, the increase in phosphorylase *a* activity by adrenaline was the more pronounced the higher the concentration of adrenaline.

It is possible that manipulation of the muscle after removal from the bath results in phosphorylase activation by cyclic 3′,5′-AMP. Since adrenaline stimulates the production of 3′,5′-AMP (ref. 9) more 3′,5′-AMP may have been available after treatment with adrenaline. Thus the formation of 3′,5′-AMP would take place in the intact tissue, while the activation of phosphorylase would take place after the removal of the tissue from the bath. In our work, during relatively short periods of manipulation, only some (less than 10 per cent) activation of phosphorylase was observed in control samples. But it has been reported[10] that, after prolonged grinding with sand, more than 60 per cent of the total phosphorylase activity in tracheal and arterial smooth muscle may be present as phosphorylase *a*. It would appear that phosphorylase *a* activity, determined after this treatment and delay, bears no relationship to the enzyme activity in the intact tissue, and the very high initial value may explain the failure to observe in these conditions a further increase after exposure to adrenaline.

Total phosphorylase activity of taenia coli varied between 2·06 and 3·88 μM of glucose-1-phosphate formed per min and per g of tissue in the absence of sodium fluoride. Fluoride in a concentration of 0·01 M inhibited total phosphorylase activity to approximately 20 per cent. Nevertheless, this concentration of sodium fluoride was used in the series of experiments summarized in Table 1 in order to ensure inhibition of the ('*PR*') enzyme converting phosphorylase *a* to phosphorylase *b*. Another series of experiments carried out in the absence of sodium fluoride, but otherwise under identical conditions, yielded the same results, that is, phosphorylase *a* activity was only increased following exposure to 5×10^{-7} M adrenaline, if homogenization was carried out after some manipulation.

It is concluded that adrenaline causes no activation of phosphorylase in the intact tissue at the time when it produces relaxation of intestinal smooth muscle by causing cessation of spike activity and hyperpolarization. Phosphorylase *a* activity may be increased afterwards by subjecting the tissue to certain manipulations, and this activation is greater after previous treatment with adrenaline. No activation is demonstrable with an improved technique. Since the changes in the electrophysiological and mechanical state of taenia coli produced by adrenaline require metabolic energy[12], it appears that biochemical mechanisms other than activation of phosphorylase or of phosphofructokinase[3] must be associated with these effects.

OVARIAN TUMOURS INDUCED BY A STERILIZING STEROID

By PROF. A. LIPSCHUTZ, DR. R. IGLESIAS and S. SALINAS

Instituto de Medicina Experimental, Servicio Nacional de Salud, Santiago, Chile

PROTRACTED sterility was induced in mice by subcutaneous pellets of 19-nor-progesterone; when the pellets were removed after 108 or 176 days (comparable with 5 or 10 years in the reproductive life-span in women) the animals recovered fertility[1]. Reproduction has been examined in these females for as long as 8 months after removal of the sterilizing pellets; reproductive behaviour remained quantitatively the same as in normal females, and the decline of fertility set in, as in the latter, at the age of about 13–14 months[2].

It was thought that experiments with protracted sterility may offer the opportunity to approach experimentally fundamental gerontological problems, that is, the mechanism underlying the decline and cessation of reproduction, as conceived already in the classic work of Hunter[3] and more recently studied by Jones and Krohn[4]. We shall not enter here into major details referring to these gerontological problems or to the results obtained in new experiments of ours in which the steroid-induced sterility was maintained in mice (*BALB*) with subcutaneous pellets of 19-nor-progesterone for as long as 13 months or more[5]. We shall deal here with only one observation.

Quite unexpectedly ovarian tumours were discovered in these animals. A detailed microscopical study of the ovaries of 33 experimental animals was made; the results were compared with those in 14 normal animals. The latter were of the same strain and of the same age (Table 1), mostly even of the same litters as the experimental animals; each normal and corresponding experimental animal was maintained during the whole life-span together in the same cage, with the male also.

Table 1

Group	Age range (average) days	Duration of treatment* days	No. of animals Total	With gran.-cell tumour	With abundant lut.-cells 'luteoma' (?)
Normal	451–705 (597)	0	14	0	0
With 19-nor-progesterone	478–718 (600)	395†–559	33	8	17‡

* Implantation of pellet every 6–7 months.
† 2 animals 375 days only.
‡ Omitting animals with granulosa-cell tumour in the contralateral ovary.

There were granulosa-cell tumours in no less than 8 animals treated for 13 months or more; the granulosa-cell tumour was unilateral in 7 cases and

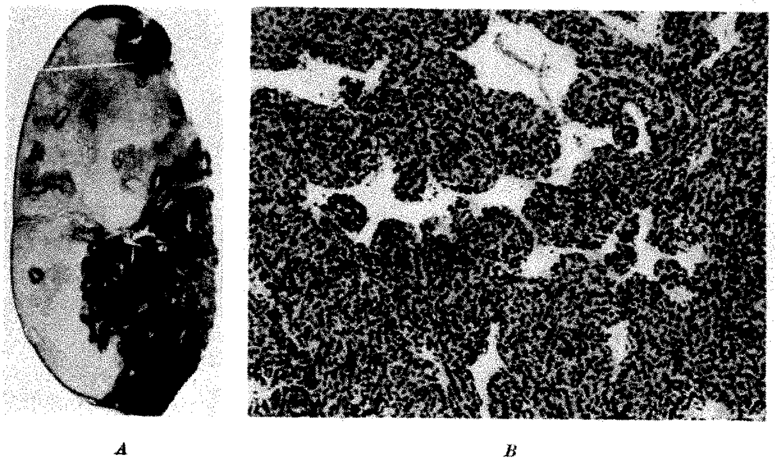

Fig. 1. 402 days with subcutaneous pellet of 19-nor-progesterone (40 per cent). Killed at an age of 693 days. Weight of right ovary, 1,250 mg. *A*, right ovary (× 5). Granulosa-cell tumour with extended degeneration of the tumour (evolutional phase 17, according to our scheme[7,8]). *B*, Same ovary (× 100). Typical granulosa-cell tumour. (Weight of the left ovary: 3 mg; great abundance of 'lutein' cells; follicles were present but no corpora lutea: non-exclusive luteoma)

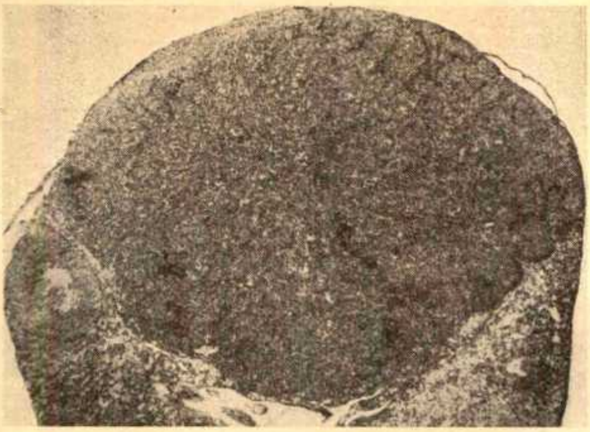

Fig. 2. 510 days with subcutaneous pellet of 19-nor-progesterone (40 per cent). Killed at an age of 591 days. Weight of the ovaries: 4 and 4 mg (× 35). Granulosa-cell tumour immediately beneath the ovarian surface, occupying great part of the ovary. Graafian follicles present; no corpus luteum. (Out of the 9 ovaries with granulosa-cell tumours 5 belonged to the type of Fig. 2, but they were smaller than the latter)

bilateral in 1 case. Examples of these tumours are given in Figs. 1 and 2.

The ovaries of most of the treated animals contained a great abundance of nodules of large cells containing vacuolated protoplasm ('lutein' cell). Similar cells are present also in the ovary of mice of normal age of different strains[6] and so also in our present strain[7]. But the difference between the ovaries of treated and normal animals with regard to size of these nodules was considerable. The nodules of large cells are very similar to those of the so-called luteoma in mice with sub-total castration and intrasplenic ovarian transplantation[8]. However, there was no 'exclusive' luteoma as in the last-mentioned experiments. Follicles, including large Graafian follicles, were absent in only 3 or 4 of the ovaries with granulosa-cell tumours; but they were present in all ovaries with the whole stroma transformed into nodules of 'lutein' cells.

It is not for us to discuss here whether our findings are of importance concerning the control of reproduction in women by the use of 19-nor-steroids. We may only mention that a steroid-induced sterility of 13 months in mice would correspond to one of 25 or more years in women; and that the use of anti-ovulatory steroids in women is never a continuous one as in our experiments in mice, but always a discontinuous one, thus allowing for regularly intercalated 'menstruations'[9]. Indeed, one may wonder whether a steroid-induced sterility of shorter duration than in our present work, or even a steroid-induced discontinuous anti-ovulatory condition as in women, may in the long run also be harmful for the ovary similarly to what happened in our experiments with protracted sterility of 13 months.

On the other hand, our results are of considerable interest from the point of view both of ovarian physiology and pathology. By the removal of CH_3 in C–19 as effected in the laboratory, transforming progesterone into 19-nor-progesterone, the progestational action of progesterone is increased about tenfold. One may then ask why the normal body is working with progesterone and not with 19-nor-progesterone; the question is quite justified in view of the fact that the body is able to remove CH_3 in C–19 as in œstrogens. Is it "The Wisdom of the Body" (these are Cannon's words) to prefer progesterone to 19-nor-progesterone, the latter being toxic since it is too active, and thus rendering rather difficult the adjustment of the progesterone homeostasis in the body? Indeed, like progesterone, 19-nor-progesterone is inactivated in the liver[10]; its metabolic fate in the body[11] also is seemingly coincident with that of progesterone. The problem of the comparative toxicity of the two compounds can be dealt with in experiments with protracted steroid-induced sterility; such work is in progress in this laboratory.

Of a more definite kind are our new findings for the understanding of ovarian pathology. From former work with sub-total castration in mice[7] and with intrasplenic ovarian grafts[12] it was concluded that there is, in these experimental conditions, an ovarian-hypophyseal imbalance primarily due to a non-adjusted steroid homeostasis. Adjustment of the steroid homeostasis was thought to be one of the bodily mechanisms of 'antitumoural autodefence'[13]. The implication of steroid homeostasis in ovarian tumourigenesis was made especially evident in experiments with combined intrasplenic and intrarenal ovarian grafts[14]. The present work with the production of ovarian tumours by the protracted administration of a steroid gives definite experimental evidence that a failure in the adjustment of the homeostasis of progestational steroids may be at the root of ovarian tumourigenesis. [*Note added in proof*. Recently granulosa-cell tumours have been elicited in female dogs by the administration of diethylstilbœstrol[22].]

Are the dynamics of ovarian tumourigenesis, as due to the administration of steroids, coincident with those in experiments with sub-total castration and intrasplenic grafts? Are the tumours induced by the administration of steroids also due to a pituitary imbalance? The same question arises in experiments in which ovarian tumours were elicited with carcinogens[15,16]; certain findings speak decidedly in favour of a pituitary imbalance being implicated in these latter experiments[15]. Since progestational steroids act on the ovary most probably via the hypophysis[17] it would seem reasonable to suppose that the same dynamics are involved also in the tumourigenic action of 19-nor-progesterone on the ovary. The very pronounced antiluteinizing action of 19-nor-progesterone has been evidenced already in former work[18]. How can then the exorbitant development of 'lutein' cells in the ovarian stroma in the present work be explained? There are two possibilities: first, that the 'lutein' cells as present in these ovaries are not to be identified with corpora lutea cells; or secondly, that the gonadotrophic functional pattern of the hypophysis which emerges from the protracted action of the progestational steroid is fundamentally different from any one hitherto known.

When contemplating tumourigenic results as obtained with partial castration or intrasplenic ovarian grafts, and now with the administration of an artificial steroid as 19-nor-progesterone, one may argue that all this is no more than experimental ovarian pathology far removed from reality. However, what comes out of this experimental pathology is but a replica of those spontaneous ovarian tumours which have been described in 11 different strains of mice[19] and in rats[20].

At the time of finishing this preliminary review of our experimental results we were impressed by reading an article just published in the *Lancet*[21] which ends as follows: "The possibility that orally active gestagens exert an unfavourable influence on the hormonal environment controlling fertilization and nidation [in women] needs to be investigated" (from Sir Solly Zuckerman's Department, University of Birmingham).

We thank Prof. Warren O. Nelson, medical director of the Population Council, New York, for financial help; Dr. Zaffaroni, for supplying 19-nor-progesterone; and Prof. Roberto Barahona, pathologist of Universidad Católica de Chile, for advice concerning examination of microscope slides.

FLUORESCENT COMPOUNDS AND NON-ENZYMATIC BROWNING

By Dr. H. S. BURTON, Dr. D. J. McWEENY, P. N. PANDHI and D. O. BILTCLIFFE

Ministry of Agriculture, Fisheries and Food, Food Science
and Plant Health Division, London, S.W.1

THE Maillard reaction, in which sugars and amino-compounds react to form brown insoluble melanoidins, has been examined by many workers[1-4]. On a number of occasions fluorescent substances have been reported both in model browning systems and in foodstuffs, but they have apparently proved intractable and their role has not been disclosed. There have been speculations that they may be by-products, and some fluorescent compounds are known to be formed from amino-acid reactions in the absence of sugar. Simonson and Tarassuk[5] observed that in milk products the development of fluorescence, browning and evolution of carbon dioxide all appeared to progress together, and speculated whether the level of fluorescence could be used as a guide to the browning potentialities of foodstuffs.

In a separate publication[6] we have mentioned the isolation of yellow fluorescent substances from scald liquor and that these substances gave brown polymers when incubated by themselves, and with glycine[7,8]. A number of crude fractions from our model browning systems have also shown a more rapid development of browning in the presence of a nitrogen function that in the presence of aldoses[9,10].

Initial investigations on sugar/amino systems (with P. J. Moody) revealed that fluorescent substances appeared in all sugar/amino-acid incubates, and that the degree of fluorescence and number of fluorescent substances increased as the incubation proceeded; the R_F values of the fluorescent zones varied with the amino-acid used.

Further investigation showed that the sugars, incubated with an amino-function, developed fluorescence much more rapidly and to a greater extent than in its absence. This occurs even at alkaline pH's which would not favour the production of furfurals. We have found that the rate of development of fluorescence of various sugars with amino-compounds in solution follows the same order as does the early browning, the less-stable sugars[11] giving a more rapid development of fluorescence, for example, aldopentoses > aldohexoses, galactose > glucose. We have already reported[12,13] an examination of sulphited glucose/glycine systems which showed that after the initial period (during which α-amino-NH_2 dropped and colourless intermediates were formed) an increase took place in the conjugated unsaturated carbonyl content of the system concomitant with an increase in the quantity of yellow fluorescent substances; colour development rapidly followed the carbonyl/fluorescence production until the later stages of the browning, when the colour deepened, presumably due to co-polymerization, while the concentrations of the conjugated unsaturated carbonyl compounds and fluorescence intensity diminished. Pre-incubated glucose solutions develop coloration more rapidly with glycine than do the fresh unheated glucose solutions, and fluorescence development was found to occur more rapidly in this case.

There seemed a strong possibility that the fluorescent compounds might be cyclic unsaturated carbonyl compounds, formed by cyclization of the unsaturated compound formed following the initial sugar carbonyl–amino group link up. It was also felt that some of the fluorescent compounds might contain nitrogen. In a semi-quantitative analysis of their impure blue/purple fluorescent fractions from the reaction between 2-*N*-acetyl-L-lysine and glucose, Hannan and Lea[14] found a nitrogen content of 5–10 per cent and a reducing action in ammoniacal silver nitrate. Their products were not furfural derivatives; one of them browned on heating. Cyclization to give a pyridine ring in a simple reaction between ammonia buffers and an unsaturated aldehyde[15,16] is already known to take place. This reaction seems explicable by the same type of mechanism which we believe occurs to give some fluorophores.

We have now examined the development of fluorescence in both sugar/amino-acid and in sugar/amino aqueous systems and have followed its development on heating dry synthetic glycosylamines. The yellow fluorescent compounds can be produced very rapidly by incubating the aqueous solutions at 50° C, and they can be selectively extracted using a range of solvents, for example, ethyl acetate, *cyclo*hexanone, *n*-butanol. From our results it would seem that the first fluorescent compounds formed from ethanolamine are hydroxylic, since they extract into butanol but not into cyclohexanone or ethyl acetate. On further incubation, we obtained yellow fluorescent fractions in each solvent, presumably due to dehydration or combination. The generation process is continuous in the early stages, since on re-incubation over four cycles the extracted aqueous residues produced a similar range of selectively extractable yellow fluorescent compounds. Haas[17] had previously extracted browning mixtures with ethyl acetate and found a multiplicity of carbonyl compounds absorbing in the conjugated unsaturated carbonyl region about 285 mμ. This continuous extraction process retarded the browning of his mixture, but even so it appears from our results that using this solvent he may not have isolated some of the first types of compound formed. Wolfrom and his co-workers had shown that the addition of dimedone removed carbonyl-compounds from glucose- and xylose-/glycine systems and thereby retarded the chromophore development of the residue.

The initial compounds isolated in our investigations on the xylose/ethanolamine system were extracted into butanol, precipitated with hexane, and the product leached with acetone and chloroform. The viscous solid remaining after this treatment was dissolved in methanol and chromatographed on 'Celite' using chloroform/methanol as solvent. The product gave two impure yellow fluorescent compounds (found, N – 15·2 per cent, 9·6 per cent) which on treatment with 2 : 4 dinitrophenylhydrazine gave 2 : 4 dinitrophenylhydrazine derivatives. On attempted acetylation of milligram quantities of the fluorophoric material with warm acetic anhydride and anhydrous sodium acetate the solution immediately darkened and the product, unlike the reactant, was soluble in acetone. However, it still gave carbonyl reactions and a precipitate with 2 : 4 dinitrophenylhydrazine. When acetylation was carried out in the cold no discoloration occurred and the product was soluble in acetone and still carbonylic in nature. The explanation may be that under warm acid conditions dehydration rapidly occurs with the production of vinyl groups, which polymerize rapidly to give a carbonyl polymer whereas in the cold, acetylation of the hydroxyl groups occurs. When the yellow fluorescent substances isolated from aqueous sugar/amino systems or from heated dry glycosylamines (which all gave 2 : 4 dinitrophenylhydrazones the spectral data of which were indicative of αβ unsaturation) were incubated alone in solution, they developed a different fluorescence. When incubated with glucose at 50° C little or no different fluorescence or colour appeared, but when incubated with glycine the fluorescence altered and the solution darkened, brown polymeric material eventually forming on the sides of the vessel. This appears to be the first proof that these fluorescent compounds are directly involved in forming melanoidins.

Shore and Purdee[18] showed that amino-acids can be detected fluorimetrically after resolution by paper chromatography, by spraying with xylose and then heating. The spray contained 1 per cent sodium sulphite to prevent loss of fluorescence and prevent the production of a brown stain. We have found that the presence of sodium metabisulphite slowed down the production of the fluorophores, which might have been expected from our previous work, but the introduction of sulphites also retarded the development of brown soluble compounds and subsequent insoluble polymers from incubates of the fluorophores. This, then, is another point at which sulphites, if present, can retard non-enzymatic browning. In the solid state we found that sodium sulphite, co-precipitated with glycosylamines by drying from an aqueous dispersion *in vacuo* over phosphorus pentoxide, also retarded development of fluorescence and brown polymer formation on heating, and a similar effect was noted when comparing the fluorescence development and browning-rates of glucose anilide and glucose-*p*-toluidide with the corresponding C_1–K sulphonated analogues by heating them in dry state at temperatures from 50° to 100° C.

The proportion of the reactive fluorescent compounds present in the heated sugar-amine compounds at any one time was expected to be low, and brown products were present, so that infra-red readings taken during the heat treatment were not unequivocal. Such indications as were obtained were not inconsistent with the development of unsaturation and cyclic nitrogen compounds.

In foodstuffs the nitrogen functions are often fixed in solid polymers. In order to simulate such a nitrogen functional surface, we incubated 50 ml. glucose/glycine mixture 2·5 M with respect to glucose and 1·0 M with respect to glycine in the presence of 0·5 g of washed, defatted wool. Within 3 days the wool, separated, washed, and dried over phosphorus pentoxide, showed a yellow fluorescence under ultraviolet light. Further 0·5 g portions of wool were admitted to and removed from the solution periodically, giving a range of darkening fluorescence on wool of increasing colour, in order light yellow → golden → cinnamon → brown. There was insufficient wool at each stage to react with all the precursors of fluorescent compounds formed, so that the various stages of the melanoidin reaction were proceeding giving deeper colours on the wool with the passage of time. (Wolfrom's work, as well as our own, showed that even at a late stage the soluble sugar/amino-acid polymers still contained carbonyl functions.)

The control solutions darkened much more rapidly than those from which intermediates had been removed by the wool at each stage, even though there was some extra oxygenation of the latter during opening and filtration.

The solutions were examined visually and measured by means of an EEL photoelectric colorimeter at 460 mμ. Results are given in Table 1.

Table 1. COLOUR DEVELOPED IN A SOLUTION 2·5 M WITH RESPECT TO GLUCOSE AND 1·0 M WITH RESPECT TO GLYCINE, INCUBATED AT 50° C IN THE PRESENCE AND ABSENCE OF DEFATTED WOOL

Incubation period (days)	Colorimeter readings	
	Control solution	Wool-treated solution
3	3·6	2·2
6	19·5	9·1
10	53	33·5
13	86	52

A similar experiment was carried out using successive additions of 2 g portions of amino-cellulose (about 1 per cent nitrogen) in place of wool. The initial solutions (60 ml.) were 1·25 M with respect to glucose and 0·5 M with respect to glycine. Similar results were obtained, though in this experiment there were sufficient amino groups to combine with the early fluorescence precursors and no colour appeared in the treated solutions until a late stage.

After 13 days' incubation the colour readings measured as here were 9·0 for the control and 0·9 for the solution treated with amino-cellulose. Analysis of the washed amino-cellulose gave an initial nitrogen content about 0·93 per cent; 0·9 per cent for the 3-day incubate; 1·4 per cent for the 6-day incubate and 1 per cent for the 10-day incubate.

From the analytical figures it would appear that the initial fluorophores and chromophores are nitrogen-containing carbonyl compounds, and that the colour developing later in the system may be due to co-polymerization with low nitrogen-containing compounds.

When incubated with sugars in the absence of glycine, fluorescence development was slower, and was again suppressed in the early stages of reaction in the solution; then it occurred only on the amino-cellulose. The fluorescent compounds formed on the fibres were not eluted by treatment with organic solvents nor with aqueous/organic solvent mixtures.

It would appear that fluorescent compounds with various side-chains might appear in the course of incubation of a hydroxy carbonyl/amino system, depending under a given set of conditions, on the sugar and on the amino compound used. These intermediate compounds will have differing reactivities which will influence the rate of polymer development. The pentoses develop yellow fluorescence rapidly when incubated with glycine, whereas glyceraldehyde does not and the mixture browns differently. This is probably bound up with a cyclization process since in the absence of aldolization there is a need for at least four carbon atoms from the carbonyl skeleton. Fructose, which develops unsaturation very rapidly on heating and develops fluorescence very rapidly when heated with aqueous ethanolamine, rapidly gives a melanoidin, with loss of fluorescence. This is in contrast with glucose systems, in which fluorescence and early browning occur somewhat later, but the more slowly developing glucose intermediates then produce a darker solution and give a darker polymer. The pentose sugars and fructose rapidly give a precipitate with ethanolamine but not with glycine, which may be due to the greater possibility of a rapid formation of a cross-linking intermediate in the former case. It would seem, too, from our experience with fructose, that the carbonyl function need not be at C_1 in the sugar series for the development of browning. Thus production of a carbonyl function anywhere in the sugar chain following dehydration might lead to melanoidin formation, provided reactive intermediates can be formed. This would appear to us to be the explanation for the rapid development of melanoidins from 2-deoxy-galactose, following a slow utilization of the NH_2 function, reported by Lea and Rhodes[19]. From these considerations one can conclude that the yellow fluorescent substances are in fact fast reacting carbonyl intermediates, active in non-enzymatic browning, and formed as a result of carbonyl-amino reactions.

We thank Mr. J. F. Hearne for initiating this project and for his encouragement in the course of the work, which is being financed under U.S. Public Law 480.

HEAT INACTIVATION OF CRYPTIC CATALASE OF YEAST

By PROF. J. GORDIN KAPLAN
Laboratory of Cell Physiology, Dalhousie University, Halifax, Canada

ONLY a small fraction of the total catalase activity of the intact, aerobically grown yeast cell can be detected *in situ*[1]; this is the patent, or whole-cell, activity. The latent, or cryptic, activity can be revealed by treating the cell with certain chemical or physical agents[1-3]; we have called this the Euler effect. Such treatment leaves all the enzyme still within the cell, which is now incapable of dividing[3], but causes alteration of certain of the properties of the enzyme.

There are three distinct hypotheses available to account for the phenomenon of enzyme latency.

(1) The interfacial hypothesis pictures all the enzyme of the intact cell adsorbed at an intracellular interface in a condition of low structural specificity, such that its specific activity is low[3]; this hypothesis has had to be abandoned in view of more recent work on the state of catalase in anaerobically grown yeast, where the patent enzyme is essentially the same as that of the aerobic cells, but where there is no cryptic enzyme[4,5].

(2) The permeability hypothesis assumes the existence of only one form of intracellular enzyme and of a barrier to penetration of substrate, such that the enzyme cannot be saturated with substrate; thus, the enzyme activity per cell is low; but there is no real difference between patent and cryptic activities.

(3) The membrane hypothesis supposes that the patent enzyme is bound to some cell membrane at which it is accessible to substrate; the cryptic enzyme is contained within the membrane and its active centre is not accessible to substrate. This hypothesis requires that there exist differences between the location and orientation of the patent and of the cryptic enzymes; it thus suggests the possibility that other enzymatic properties might differ as well.

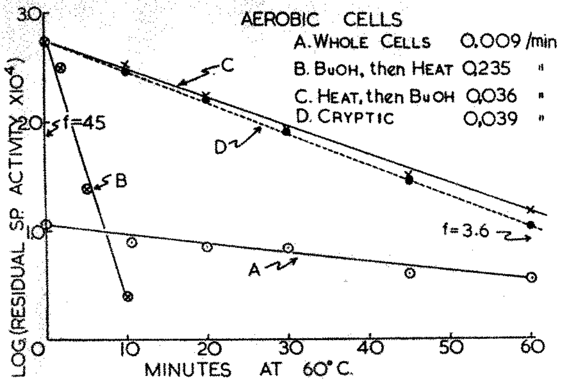

Fig. 1. Rates of heat inactivation of intracellular catalase of aerobic yeast

One property of the cryptic enzyme which can readily be examined and which can serve as a basis of comparison with the patent enzyme is the rate at which it is inactivated by heat.

Suspensions of yeast cells (*S. cerevisiae*) in M/15 phosphate buffer, pH 7·0, were placed in a water bath maintained at 60° ± 0·1° C, and aliquots were withdrawn periodically. The catalase activity of a portion of the sample was determined directly; this was the residual patent activity. The residual total activity was determined by treating the remainder of the aliquot with n-butanol (final concentration 0·8 M), as previously described[3]. The cells were then washed and resuspended in buffer for catalase determination. In some experiments, cells which had previously been treated with butanol and then washed and resuspended in buffer to the original cell density were placed in the water bath alongside the suspension of untreated cells. Enzyme assays were performed by following the decrease in absorption at 240 mμ of 0·013 M hydrogen peroxide, using a Beckman model *DU* spectrophotometer. With this method of assay, the cryptic factor (the ratio of the activity of butanol-treated cells to that of the untreated cells) was about 40–80 in aerobic yeast.

The results of a typical experiment are shown in Fig. 1. Curve *A* represents the decrease in residual patent activity of a suspension of untreated aerobic cells. Curve *C* represents the decrease in total catalase activity of the same suspension, determined after subsequent butanol treatment of the heated cells. The difference between curves *A* and *C* is obviously due to the presence of cryptic enzyme; it is apparent that the cryptic activity was much more rapidly inactivated by heat. During the heating, the cryptic factor diminished from 45 in the unheated cells to 3·6 in those heated for 60 min. Curve *B* demonstrates the high heat lability of catalase in cells treated with butanol and other agents which reveal all of the cryptic activity[2].

It is possible to determine the rate of heat inactivation of the cryptic enzyme itself by subtracting arithmetically the residual patent activities (the logarithms of which are shown in curve *A*) from the residual total activities. Correcting thus for the high heat resistance of the patent enzyme, one sees from curve *D* that the cryptic enzyme has been inactivated at a slightly higher rate than the total activity; the difference is 10 per cent or less, and we may thus take the rate of decrease of total activity (curve *C*) as measuring in effect the heat sensitivity of the cryptic catalase.

During the anaerobic growth of an initially aerobic yeast suspension, the cryptic factor of catalase diminishes with each cell division[5] and approaches unity in about 7 divisions. When the cryptic factor was unity (actually it might vary from 0·8 to 1·8, depending, among other things, on the temperature of assay), post-treatment of heated cells did not significantly change the activity of the suspension: that is, curve *C* coincided with curve *A*. It was of interest to examine the heat-sensitivity of the cryptic enzyme in a culture which had grown anaerobically for several generations, such that the quantity per cell of cryptic enzyme had been greatly reduced, but not eliminated. A series of experiments was performed in which the initial cryptic factor before heating varied from about 3 to 5.

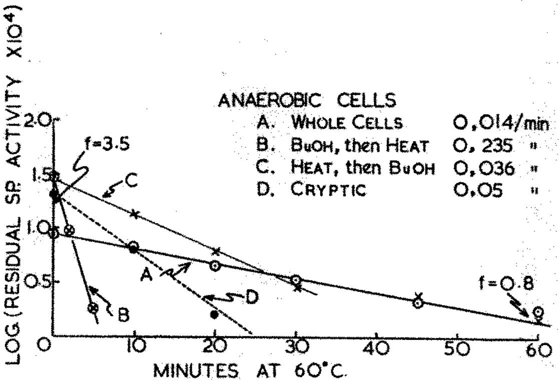

Fig. 2. Rates of heat inactivation of intracellular catalase of an originally aerobic yeast suspension, grown anaerobically for several generations

The results of such an experiment are shown in Fig. 2. The slopes of curves *A*, *B* and *C* are about the same as for the aerobic cells. However, curve *C* shows an abrupt change in slope when all the cryptic catalase has been inactivated, the curve thereafter coinciding with curve *A*. Curve *D* shows the decline in the cryptic activity. Since the difference in slope of curves *C* and *D* was relatively small (10–25 per cent), one may safely take curve *C* to measure the heat sensitivity of the cryptic catalase. The results from experiments of this type are summarized in Table 1, section II. The difference between the rates of inactivation of patent (column *D*) and cryptic (column *F*) activities is highly significant. There is no significant difference between the heat sensitivity of patent, cryptic and butanol-altered enzymes of the aerobic yeast on the one hand, and

Table 1. MEAN RATES OF INACTIVATION OF INTRACELLULAR CATALASE AT 60° C
(Standard errors of the mean are shown)

I. Aerobic cells			II. Anaerobic cells		
A. Whole cells (patent)	*B*. Butanol, then heat (altered)	*C*. Heat, then butanol (cryptic)	*D*. Whole cells (patent)	*E*. Butanol, then heat (altered)	*F*. Heat, then butanol (cryptic)
0·011 ± 0·002 $n = 11$	0·25 ± 0·04 $n = 5$	0·037 ± 0·003 $n = 10$	0·012 ± 0·002 $n = 10$	0·19 ± 0·02 $n = 6$	0·037 ± 0·003 $n = 10$

Differences between means, with standard errors of the difference: *A–C*: 0·026 ± 0·004; $P < 0·01$. *D–F*: 0·025 ± 0·004; $P < 0·01$
A–D, *B–E*, *C–F*, not significantly different.

of the same categories of enzyme in aerobic yeast on the other.

Treatment of the cells at 60° C did not affect the energy of activation of the patent enzyme-substrate system, which remained approximately 9 kcal/mole throughout the experiment.

We may conclude that in the intact aerobic yeast cell the enzyme catalase exists in two distinct forms, cryptic and patent. The cryptic enzyme is three times as rapidly inactivated by heat as the patent enzyme. In cells which have grown anaerobically for several generations, one can eliminate selectively all the cryptic catalase, because of its relatively great sensitivity to heat. Treatment of the cells with butanol reveals the latent activity without removing it from the cell, but alters both the patent and cryptic enzymes to a third form, which is extremely heat labile.

In a subsequent article, it will be shown that during anaerobic growth, where there is inhibition of catalase synthesis, the cryptic catalase is progressively converted into the patent form. In terms of the membrane hypothesis, the cryptic enzyme becomes bound to specific membrane sites during growth under conditions where synthesis of new enzyme is prevented.

ACTION OF SAPONIN ON BIOLOGICAL CELL MEMBRANES

THE tacit assumption made by Dourmashkin, Dougherty and Harris[1] to explain the hexagonal structure of some virus and mammalian cells treated with saponin was that, by removal of certain lipid components, an ordered membrane structure was revealed. Schulman and Rideal[2], however, showed that saponin from an aqueous phase could penetrate into, and complex with, a number of surface-absorbed lipids—particularly cholesterol—to form very insoluble complexes. This suggested to us that the structures revealed by Dourmashkin[1] resulted from addition to, rather than subtraction from, components of the cell membrane.

That the membrane after treatment assumed an ordered structure resembling a hexagonal lattice was, perhaps, to be expected in the light of the work of Luzzati and Husson[3], who have shown recently that binary mixtures of soap and water can exhibit a hexagonal lattice structure as one of a number of characteristic phases if conditions of concentration and temperature were right. They also showed by X-ray diffraction that multi-component mixtures of brain lipids showed a similar structure as a transitional phase between that of a crystalline solid (coagel) and typical laminar structure of a liquid crystal. Stoeckenius[4] has confirmed the existence of this phase by electron microscopy in identical material but fixed with osmium.

To test the hypothesis that the pattern obtained by Dourmashkin[1] represented a transitional phase, of a mixture of saponin–water–membrane lipids (cholesterol constituting approximately 50 per cent of the lipids), we dried down pure solutions of either lecithin, lecithin and cholesterol or cholesterol alone on to carbon-coated cellulose grids. We then placed a drop of an aqueous solution of sodium phosphotungstate 1 per cent containing white saponin 0·005 per cent on the grid and after 30 sec drained the drop away and examined the grid in an Elmiskop I (Siemens) microscope. The result of such a procedure is shown in Fig. 1. The centre-to-centre spacing of the lattice is about 140 Å and the diameter of the hole 80 Å, both values being in good agreement with those found in cell membranes. It is clear that the pattern obtained is remarkably similar to that obtained by Dourmashkin[1] and Stoeckenius[4]. A similar picture can be obtained if a monolayer of cholesterol is lifted on to a grid and afterwards

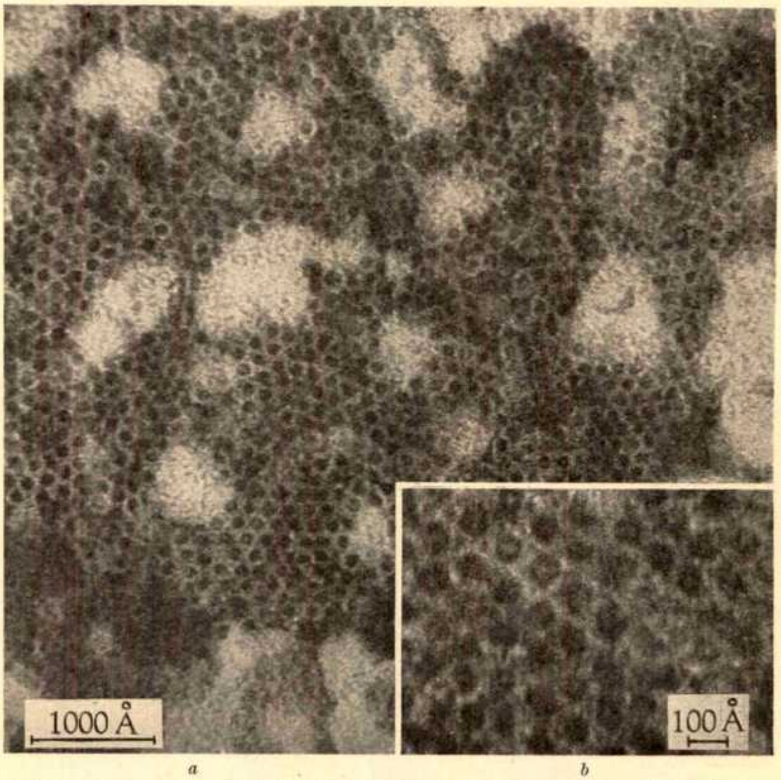

Fig. 1. Electron micrograph showing a negatively stained preparation of cholesterol after treatment with saponin. (*a*) A region at low magnification showing the network interspersed with unreacted material (× *c*.160,000); (*b*) an area at higher magnification showing the hexagonal packing of rings. (× *c*. 500,000)

allowed to react with the drop of saponin containing sodium phosphotungstate. The pattern obtained with equal molecular mixtures of lecithin and cholesterol is more heterogeneous. Many areas show a disruption of the hexagonal lattice with the appearance of free rings of lipid, some of them showing the vestigeal corners from adjacent rings. The dimensions of the free rings are also in good agreement with those observed by Dourmashkin *et al.*[1], although the piling of ring on ring has not yet been seen (Fig. 3). The hexagonal structure was rarely seen after treatment of pure lecithin and, instead, the typical laminar structure of lecithin in water was observed.

The implications of these findings are probably more germane to the functions of lipid membranes in terms of their permeability than to any interpretation as to their structure. It would seem improbable that holes of the size produced by saponin also occur in intact cells following a similar phase change. On the other hand, it is to be expected that this phenomenon will be encountered with a number of compounds known to modify membrane permeability, each producing a characteristic hole-to-surface ratio. Vitamin A alcohol, for example, appears to react with monolayers of lecithin in much the same way as saponin reacts with cholesterol[5]. It is also lytic for red cells[6], mitochondria[7,8] and lysosomes[9]. Furthermore, assuming that there is a selectivity of lipids participating in the phase change generally, or in the composition of the lipids lining the holes in particular, a mechanism for selective permeability is apparent. The role of long-chain cations in preventing extreme degrees of cell permeability may be explained in these terms[10].

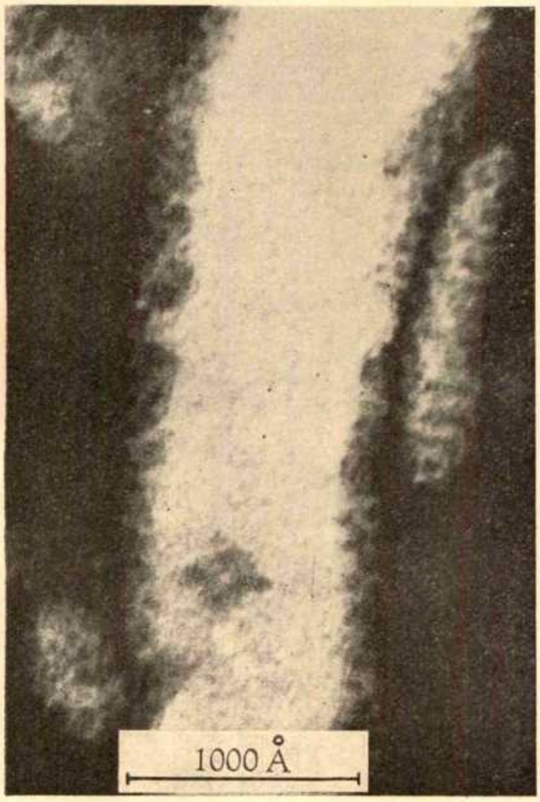

Fig. 2. Shows a relatively thick layer of cholesterol after treatment with saponin revealing the phase change occurring on the surface. (× 300,000)

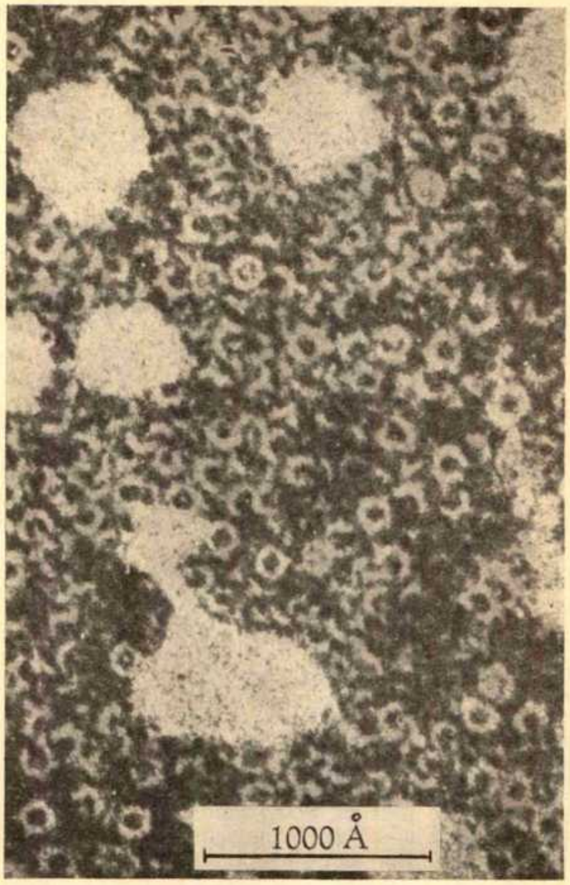

Fig. 3. A preparation of equal parts of lecithin and cholesterol treated with saponin showing separation of ring-like structures. (× 300,000)

Finally, the precise interpretation of Schulman and Rideal's original phase boundary potential and surface expansion data are now subject to some suspicion if the phase structure of a penetrated monolayer is indeed, hexagonal.

ELEGANT electron micrographs recently published by Dourmashkin, Dougherty and Harris[1] demonstrated the presence of holes or pits in the surface membranes of Rous sarcoma viruses, erythrocytes and tissue cells after treatment with saponin. When a sufficiently high concentration of saponin was used, many holes were produced which were arranged in a hexagonal array. The holes or pits varied in size from 70 to 95 Å in diameter according to the membrane studied, and each was surrounded by a ring some 30–50 Å wide. It was suggested by Dourmashkin *et al.* that "the almost identical appearance of the saponin-treated cell membranes from such disparate species as chicken, guinea pig and man lends credence to a general theory for the structure of the cell membrane". Furthermore, these workers suggested that their observations were in fair agreement with the mosaic structure of lipid and non-lipid areas proposed by Parpart and Ballentine[2] for cell membranes in which cylinders of phospholipid and cholesterol, having a diameter of about 90 Å and a centre-to-centre spacing of approximately 150 Å, were surrounded by a meshwork of protein.

Saponin has the ability to form a complex with cholesterol. The production of pits or holes in a membrane containing cholesterol by treatment with saponin might therefore be thought to result from removal of cholesterol from the membrane by the saponin solution. However, when saponin molecules are injected beneath a monolayer of cholesterol, combination does occur, but in this instance the saponin molecules are incorporated into the structurally orientated monolayer of cholesterol. This is shown by the rapid increase in the surface pressure of the cholesterol film as the saponin molecules penetrate the monolayer[3].

Since treatment of cell membranes with saponin resembles treatment of a cholesterol monolayer with saponin, it seemed possible that the hexagonal pattern seen in saponin-treated membranes represented the molecular orientation of the lipids of the cell membrane after penetration by saponin molecules.

It was therefore of interest to see if the dimensions of saponin molecules bore any relationship to the hexagonal pattern of the treated membranes. Measurements of a model of a saponin-type glycoside showed that the lipid-soluble steroid ring system, or triterpene system, which comprises the 'head-group' of such a glycoside is of the order of 10 Å by 16 Å. The water-soluble chain, assuming it to be composed of five sugar molecules as occurs in many saponins, is approximately 25 Å long. If saponin molecules were arranged in a two-dimensional micellar-type structure in a lipid monolayer with the lipophilic head groups on the outside where they would be associated with the original lipid of the film, the hydrophilic sugar chains of the saponin molecules would be in a central aqueous phase that might appear as a dark hole on negative staining with phosphotungstate.

Close inspection of electron micrographs of saponin-treated Rous sarcoma cell and erythrocyte membranes published by Dourmashkin *et al.*[1] indicated the presence of approximately twenty sub-units in the 30–50 Å wide rings which surround each central dark hole. Arrangement of twenty saponin molecules in a circular structure with a distinguishable space between each lipophilic head-group would produce a ring having a central hydrophilic hole, approximately 80 Å in diameter, that would contain the sugar moieties of the saponin molecules. Interaction of cholesterol molecules and the lipophilic heads of the saponin in a 1 : 1 molar ratio on the outside of the circular structure would then give a ring of approximately 30 Å in width composed of discrete sub-units (Fig. 1). Since the dimensions of this hypothetical structure are similar to those of the holes and rings in saponin-treated membranes, it was decided to treat a simple monolayer of cholesterol with saponin in the absence of protein to see if a similar hexagonal pattern could be produced. We made the test experiment on October 26, 1962; we were unaware of the experiments being made simultaneously by A. D. Bangham and R. W. Horne at Babraham (previous communication).

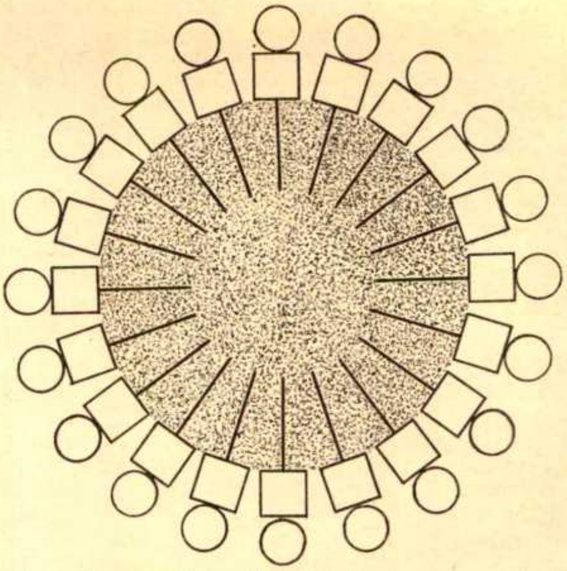

Fig. 1. Diagram of the hypothetical micellar-type arrangement of saponin (□) and cholesterol (○). The central speckled area represents the water phase

A drop of a dilute solution of cholesterol (2 mM) in petroleum ether (b.p. 40°–60°) was placed on the surface of distilled water (60 ml.) contained in a Petri dish. All water used in the experiment had been passed through a sterilizing filter. After the petroleum ether had evaporated from the surface, a 1 per cent aqueous solution of saponin (3 ml.) was injected through the film into the water below the

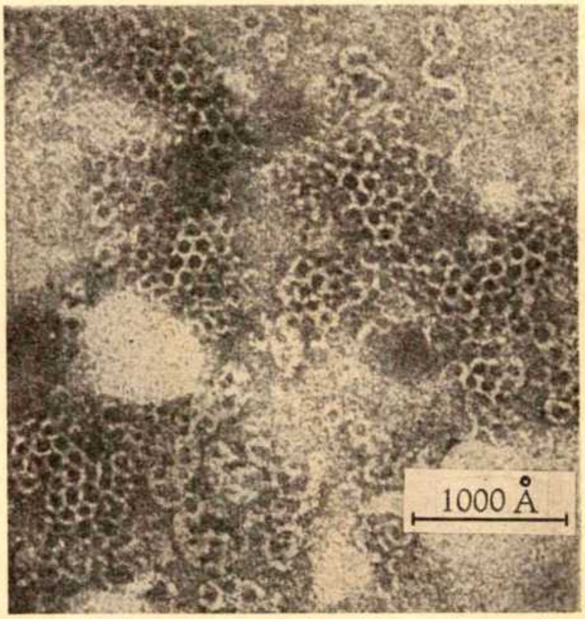

Fig. 2. Electron micrograph of a film of cholesterol treated with saponin and then negatively stained with potassium phosphotungstate. (× 200,000)

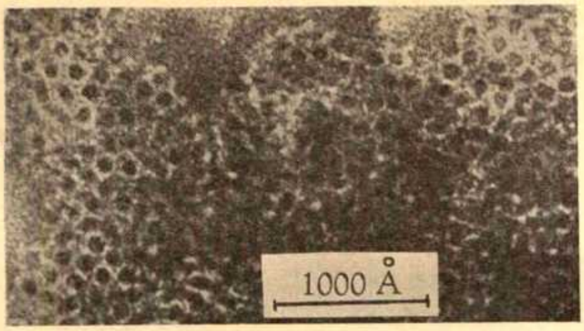

Fig. 3. Electron micrograph of a fragment of a rabbit erythrocyte haemolysed with saponin and then negatively stained with potassium phosphotungstate. (× 200,000)

cholesterol and the mixture stirred by pipetting the bulk phase up and down several times. A portion of the surface film was collected on an electron microscope grid coated with collodion and carbon, by dipping the grid through the film. A drop of a solution of potassium phosphotungstate (0·5 per cent; pH 7) was then placed on the surface of the grid and afterwards withdrawn with filter paper. Micrographs were taken with a Siemens Elmiskop I.

Fig. 2 shows an electron micrograph of a negatively stained preparation of cholesterol after treatment with saponin in the manner described. A hexagonal arrangement of holes can be seen in certain areas; individual holes have a diameter of approximately 80 Å. Rabbit erythrocyte ghosts which had been treated with saponin in this laboratory by the technique of Dourmashkin *et al.*[1] are shown in Fig. 3. A comparison of the two patterns shows that they are very similar. It is suggested therefore that the hexagonal structure that is produced by adding saponin to preparations of cell membranes represents primarily the molecular arrangement of a complex of saponin with cholesterol, and does not represent any pre-existing arrangement of lipid and protein in the cell membrane as inferred by Dourmashkin *et al.*[1].

The findings of Dourmashkin, Dougherty and Harris remain of great interest, however, when interpreted as demonstrating the addition of saponin to the cell membrane rather than a loss of cholesterol from the membrane. Their observations appear to show that extensive re-arrangement of membrane lipids can occur in the presence of suitable agents. The incorporation of saponin into the cell membrane probably forms a structure that is more permeable than the original membrane, since the structure containing saponin has areas 80 Å across that seem to contain water. The production of these holes through the lipid component of the cell membrane probably constitutes the hæmolytic mechanism of saponin. Other compounds of biological significance such as vitamin A which, like saponin, is hæmolytic[4,5], and can penetrate lipid monolayers[6], may produce similar changes *in vivo*, and furthermore, such changes may be reversible. It is possible that reversible alterations in lipid structure of this kind produced in the cell membrane by compounds such as vitamin A may be concerned in controlling the permeability of cells under normal physiological conditions.

ROLE OF ISOCITRATE LYASE IN SYNTHESIS OF OXALIC ACID IN PLANTS

By DR. ADELE MILLERD, PROF. R. K. MORTON and J. R. E. WELLS

Department of Agricultural Chemistry, Waite Agricultural Research Institute, University of Adelaide

BOTH the non-photosynthetic and the green tissues of *Oxalis pes-caprae*, a weed of economic significance in South Australia, contain up to 16 per cent of the dry weight as oxalic acid; the pH of the expressed sap is about 2. With compounds labelled with carbon-14, we[1] have shown that glyoxylic and glycollic acids are immediate precursors of the oxalic acid formed in the white emergent shoots from the starchy bulbs of this plant. These investigations[1] excluded the fixation of carbon dioxide (which occurs in many photosynthetic tissues) and de-amination of glycine (or of serine) as major physiological pathways for formation of glyoxylic and glycollic acids, which appeared to arise directly from the sugar or tricarboxylic acid pools. From the results of Carpenter and Beevers[2], it has hitherto been considered that isocitrate lyase (L_s-isocitrate glyoxalate-lyase, formerly known as isocitritase[3]) occurs only in those plants which actively convert fat to carbohydrate, a condition which does not apply to *Oxalis*. Moreover, since Clagett *et al.*[4] had found glycollate oxidase in green tissues but absent from embryos and etiolated plants, it appeared likely that this enzyme was restricted to photosynthetic tissue.

It has now been shown that the following enzymatic reactions occur in extracts from the white shoots of *Oxalis pes-caprae*:

$$\text{isocitric acid} \rightarrow \text{glyoxylic acid} + \text{succinic acid} \qquad (1)$$

$$\text{glycollic acid} + A \rightarrow \text{glyoxylic acid} + AH_2 \qquad (2)$$

$$\text{glyoxylic acid} + A \rightarrow \text{oxalic acid} + AH_2 \qquad (3)$$

$$\text{glyoxylic acid} + \text{NADP.H}_2 \rightarrow \text{glycollic acid} + \text{NADP} \qquad (4)$$

$$\text{oxalic acid} + \text{NADP.H}_2 \xrightarrow{\text{CoA}} \text{glyoxylic acid} + \text{NADP} \qquad (5)$$

here A is 2 : 6-dichlorophenol indophenol, or oxygen, and NADP and NADP.H_2 are the oxidized and reduced forms of coenzyme II respectively, and CoA is coenzyme A. Reaction (1) is catalysed by isocitrate lyase and reactions (2) and (3) by flavin-linked oxidase (or oxidases). Reaction (4) is catalysed by a glyoxylate reductase, and reaction (5) probably involves the intermediate formation of oxalyl–CoA.

Isocitrate lyase. The enzyme was demonstrated with an extract of an acetone powder of a particulate fraction from an homogenate of white *Oxalis* shoots. Several different methods gave confirmatory results.

(*a*) With reduced glutathione, Mg^{2+} ions, and the enzyme preparation, DL-isocitric acid was converted to a keto-acid as shown spectrophotometrically at 252 mμ by formation of the semi-carbazone. Under the conditions used, keto-acid formation was 0·084 O.D. units per mg of protein per min at *p*H 6·0 and at 25° C. After treatment of the enzyme extract with acid-washed charcoal ('Norite' *SX*-2) to remove nicotinamide nucleotide co-enzymes and so to prevent the possible formation of α-oxoglutaric acid by the action of isocitrate dehydrogenase, the rate of keto-acid formation was 0·055 O.D. units per mg of protein per min.

(*b*) The enzyme preparation was incubated at *p*H 7·5 with DL-isocitric acid, Mg^{2+} ions and cysteine; samples were removed at various intervals after commencement of the reaction and autoclaved at 15 lb. for 15 min with 2 : 4-dinitrophenyl hydrazine to decompose the glyoxylate–cysteine complex[5]. There was a linear increase in extinction at 435 mμ with time. Total keto-acids were assayed according to Friedman[6], and characterized by the absorption spectra of the 2 : 4-dinitrophenyl hydrazones. This method enabled correction for α-oxoglutaric acid initially present in the crude enzyme preparation, and clearly showed that glyoxylic acid was formed enzymically from DL-isocitric acid.

(*c*) The enzyme preparation was incubated at *p*H 6·0 with reduced glutathione, DL-isocitric acid and Mg^{2+} ions; glyoxylic acid formation was measured by the semicarbazide method, and succinic acid formation by specific enzymatic reduction of ferricytochrome *c* catalysed by succinate dehydrogenase[7]. Under the conditions used, 0·13 μmoles of glyoxylic acid and 0·12 μmoles of succinic acid were formed in 53 min, in good agreement with the stoichiometry of the reaction catalysed by isocitrate lyase.

The *in vivo* activity of the enzyme was shown by injecting ^{14}C-labelled isocitric acid into *Oxalis* shoots. Extracts were prepared from the shoots and the compounds containing isotope were separated by paper chromatography and detected by autoradiography[1]. Because of its instability, glyoxylic acid was difficult to detect but succinic and oxalic acids both contained considerable amounts of isotope; citric and α-oxoglutaric acids also contained appreciable amounts of isotope but glycollic and malic acids contained significantly less.

Oxidation of glyoxylic and glycollic acids. When injected into *Oxalis* shoots, isotope from ^{14}C-labelled glycollic acid appeared in about equal amounts in glyoxylic and oxalic acids, and isotope from ^{14}C-labelled glyoxylic acid was equally distributed between glycollic and oxalic acids[1].

At *p*H 7·8, in the presence of added riboflavin phosphate, glycollic and glyoxylic acids were oxidized by an enzymatic extract of *Oxalis* shoots, as demonstrated manometrically by oxygen uptake and spectrophotometrically by reduction of 2 : 6-dichlorophenol indophenol at 600 mμ (reactions (2) and (3)). The initial rate of oxidation of glyoxylic acid, measured spectrophotometrically, was approximately 60 per cent of the rate of oxidation of glycollic acid. These oxidations are probably catalysed by a flavoprotein similar to glycollate oxidase of other plants[8].

Reduction of oxalic and glyoxylic acids. It was apparent from studies with *Oxalis* shoots that isotope from ^{14}C-labelled glyoxylic acid appeared in glycollic acid, and that isotope from ^{14}C-labelled oxalic acid appeared in small amounts in glycollic and glyoxylic acids[1].

Reaction (4) was demonstrated spectrophotometrically at 340 mμ by a glyoxylic acid-dependent oxidation of either NAD.H_2 or of NADP.H_2 at *p*H 7·4 in the presence of an extract of *Oxalis* shoots. The initial rate with NADP.H_2 was about twenty times greater than that with NAD.H_2. The coupled reactions (3) and (4) would account for the dismutation of glyoxylic acid to glycollic and oxalic acids[1].

With a similar extract, at *p*H 8·3, NADP.H_2 was also oxidized in the presence of cysteine, adenosine triphosphate (ATP), Mg^{2+}, succinic acid and oxalic acid. There was no oxidation in the absence of oxalic acid or of any of the co-factors. It is therefore probable that reaction (5) proceeds via oxalyl–CoA. This intermediate has been shown to be formed from oxalic acid, succinic acid, ATP and CoA with an enzyme system of *Pseudomonas oxaliticus*[9].

Metabolism of Oxalis. The metabolic reactions of *Oxalis* related to the synthesis of oxalic acid are shown in Fig. 1.

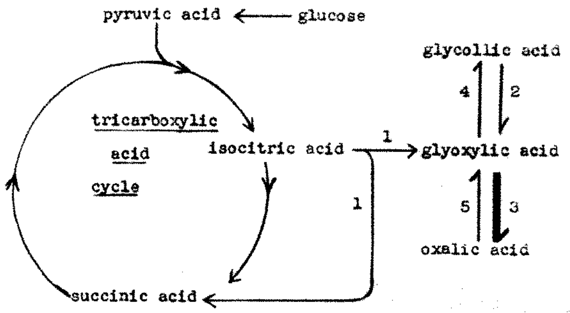

Fig. 1. Pathway of synthesis of oxalic acid in *Oxalis*. The numbers refer to the following enzymes: 1, isocitrate lyase; 2 and 3, flavin-linked oxidase (or oxidases); 4, NADP-linked glyoxylate reductase; 5, an enzymatic system involving formation of oxalyl-CoA

Since formation of oxalic acid appears to be an essential feature of the metabolism of *Oxalis* and is dependent on isocitrate lyase, an enzyme of restricted occurrence in plants[2], specific inhibition of isocitrate lyase offers a possible means of selective control of this and related weeds; work on potential inhibitors is therefore in progress.

CONTRACTION OF KERATIN FIBRES IN AQUEOUS LITHIUM BROMIDE

By M. FEUGHELMAN, A. R. HALY and P. MASON

C.S.I.R.O. Wool Research Laboratories, Division of Textile Physics, Ryde, Sydney

WHEN an α-keratin fibre is immersed in aqueous lithium bromide solution its length may stay unchanged, may decrease reversibly or may decrease irreversibly to a greater degree, the actual behaviour depending on the type of fibre, the concentration of the solution and the temperature[1,2]. These 'super-contraction' phenomena have recently been re-examined by Mandelkern, Halpin, Diorio and Posner[3] in relation to studies of phase transitions in partly crystalline polymers. After confirming the correlation between super-contraction and disappearance of crystallinity (as indicated by X-ray diffraction technique) Mandelkern *et al.* drew an analogy between this situation and melting in crystalline and cross-linked rubber or polyethylene. Thus they represent the fibre in its initial state as a cross-linked two-phase system of crystallites and matrix, in which reversible super-contraction corresponds to the melting of the crystallites, either thermally or by chemical action, and irreversible super-contraction occurs when the cross-links are broken. They further suggest that the introduction of more complex models is unwarranted.

It seems necessary to point out that although the foregoing model is adequate to account for super-contraction in keratin fibres, and was in fact originally used by us in this way[4], it has to be rejected as incorrect when the following properties are considered[5]: (*a*) the longitudinal mechanical behaviour (load-extension, stress-relaxation, creep) of single keratin fibres in water in the hookean, yield and post-yield regions, together with the associated X-ray patterns; (*b*) the relationship between force per unit extension of single keratin fibres in concentrated aqueous lithium bromide at the end of both first and second stages of contraction, and the amount of the respective contractions.

All these properties can be consistently explained by assuming the existence in the keratin structure of long crystalline microfibrils aligned parallel to the fibre axis and embedded in a non-crystalline matrix[6]; along these microfibrils alternate regions (*X*- and *Y*-zones) are postulated, the two types of zones having different mechanical properties[5]. Extension in the yield region and first-stage super-contraction take place in the *X*-zones, while extension in the post-yield region and second stage super-contraction take place in the *Y*-zones.

A detailed discussion of this model and its relationship to electron microscope, infra-red and X-ray results was reported at a recent conference on wool structure[7]. Three points may be emphasized with regard to the structure of wool and hair keratin.

(1) It is now well established from evidence based on a wide variety of experimental techniques[6,7] that α-keratin fibres consist of long. aligned microfibrils of 70–80 Å diameter separated by a matrix. These microfibrils are aligned in the direction of the fibre axis and are identified with the crystalline phase of the wool fibre; the matrix is not crystalline. Electron microscope[8,9] evidence suggests that the microfibrils are long and possibly run the full length of a cortical cell (*c.* 100μ). It follows that the extension of the fibre as a whole corresponds closely to the extension of the microfibrils.

(2) As a wool fibre in water at room temperature is extended from the yield region (about 2–30 per cent extension) into the post-yield region (beyond about 30 per cent extension) there is a rapid stiffening of the fibre, the incremental modulus being an order of magnitude greater than in the yield region (Fig. 1). The high-angle X-ray diffraction[10] pattern shows a continuous decrease of crystalline α-keratin with increase of extension (Fig. 1). The major part of the α-type crystallinity is still present at the turn-over from the yield to post-yield regions and a significant proportion is still present at extensions well into the post-yield region.

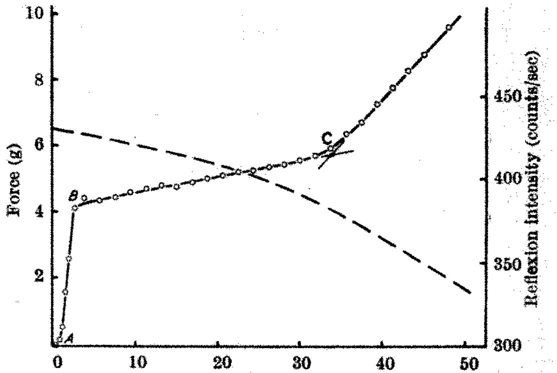

Fig. 1. –○–, The load-extension curve of a Corriedale wool fibre in water at 20° C was obtained by extending in steps indicated by the experimental points, the values of force being measured after the fibre had been held 24 h at each extension. The section *AB* of the curve is the hookean region, *BC* is the yield region, and extensions higher than *C* correspond to the post-yield region; – – –, values of the intensity of the 5·1 Å meridional reflexion of α-keratin fibres at varying extensions, as measured by Bendit (ref. 9)

At the turn-over extension between the yield and post-yield regions, the bonds opposing extension into the post-yield region must be either in the α-keratin crystallites still present or in the matrix immediately surrounding these crystallites. As pointed out elsewhere[7] the latter proposition is favoured. However, in either case these crystallites and their neighbouring matrix form the *Y*-zones that open out in the post-yield region, the *X*-zones having been opened out in the yield regions. Although the introduction of *X* and *Y* zones is in the first instance purely formal, it is quite plausible that real differences in physico-chemical structure should exist; for example, in cystine content or in degree of cross-linking. The essential feature is that each *Y*-zone should be large enough to contain a sufficient number of unit cells of the α-helix structure to preserve the 5·1 Å reflexion after the *X*-zones have extended. Since the bonds controlling the rate of contraction in the second stage for wool fibres in concentrated lithium bromide have been correlated with the bonds controlling the stiffness of the fibres in the post-yield region[7], it follows that contraction must also be considered in terms of the series zone model.

(3) The sharpness of the change of slope of the load-extension curve between the yield and post-yield regions also suggests the existence of two distinct zones rather than a distribution of cross-links and entanglements. In the latter case one would expect a more gradual increase in stiffness from the yield to post-yield regions as the progressive opening-up of the keratin structure is opposed by more and more of the randomly distributed bonds.

Finally, we suggest that the observation by Mandelkern *et al.*[3] that fibres in 12 M aqueous lithium bromide do not contract at 24° C may be an artefact. Keratin fibres placed in concentrated lithium bromide solution dehydrate rapidly to the state corresponding to the relative humidity above the solution. The lithium bromide penetrates as a front into the fibre, the rate of penetration being very dependent on the moisture content of the fibre. For Corriedale wool fibres (diameter *c.* 50μ) the times of penetration[1] at room temperature are 30–45 min in 6·3 M lithium bromide, 5–7 h in 8·3 M lithium bromide, and 7–8 days in 10·4 M lithium bromide. Moreover, no contraction occurs until the fibre is nearly completely penetrated. In 12 M lithium bromide solution moisture equilibrium[11] is reached with a relative humidity of 3–4 per cent and penetration of the lithium bromide into wool would be extremely slow, requiring, at 20° C, weeks and possibly months. For horse-hairs these times would be even longer.

DERMOCYSTIDIUM GASTEROSTEI n. sp., A PARASITE OF *GASTEROSTEUS ACULEATUS* L. AND *GASTEROSTEUS PUNGITIUS* L.

By DR. E. ELKAN

Group IX Laboratories, Shrodells Hospital, Watford, Herts.

THE genus *Dermocystidium* is much ignored, even by parasitologists. Grassé (1953), in his text-book on protozoology, mentions only one species while neither Kudo (1960) nor Hyman (1940) mentions the genus at all. Doflein and Reichenow[1], however, remind us that at that time six different species of *Dermocystidium* had been described. Even their list was, however, incomplete because it ignored *D. percae*, described by Reichenbach-Klinke in 1950[2].

The genus was established by Pérez in 1907[3] from observations on the contents of dermal cysts in newts infected with *Dermocystidium pusula* P. In 1921 Guyénot and Naville[4] described *D. ranae* from *Rana temporaria* and *Rana esculenta* as well as from *Alytes obstetricans*. Léger[5] found *D. branchialis* on the gills of *Trutta fario*; Jirovec[6] described *D. vejdovskyi* from the pike (*Esox lucius* L.).

Authors usually list *Dermocystidium* with the Sporozoa and regard it as a member of the Haplosporidia. This classification of the genus is based on the presence of a lid in the spores. It may not be final because in some species the lid cannot with certainty be demonstrated.

The investigation reported here was undertaken with the object of elucidating the nature of a disease observed among sticklebacks (*Gasterosteus aculeatus* L. and *G. pungitius* L.) in waters around Newdigate, Surrey. After the fairly severe winter of 1961–62 numerous specimens of both species were caught in May presenting the picture as shown in Fig. 1. Spring and early summer remained cold, and specimens similarly afflicted were caught up to the middle of June. With the appearance of warmer weather towards the end of June the gross manifestations of the disease disappeared, but fish with minute white cysts on their dorsal and tail fins could still be found.

Attempts to take swabs from these cysts while the fish were alive failed. Nor was it possible to remove any cysts *in toto* from live specimens. This failure is easily explained by a glance at a section (Fig. 3), which shows that the cysts do not lie on the surface but in the dermis and that many of them—not all—have a thick and resistant cyst wall. The impression that the cysts lie on the surface is derived from the extreme transparency of the epidermis covering them. Smears from cysts contents could only be made by opening them with a fine scalpel and squeezing the contents out on glass slides. Smears and sections were fixed with methyl alcohol, formaldehyde, weak Flemming's solution or Carnoy's solution and stained after Giemsa by McNamara's method as modified by Shortt and Cooper[7], hæmatoxylin–eosin or by the periodic acid–Schiff reaction.

At the height of the epizootic the fish were covered with structures looking at first sight like 'white worms'. Closer examination showed these structures to be cysts, 2–3 mm long and 0·2–0·3 mm wide, either straight or bent, of even thickness or club-shaped. On the tail fin their arrangement was

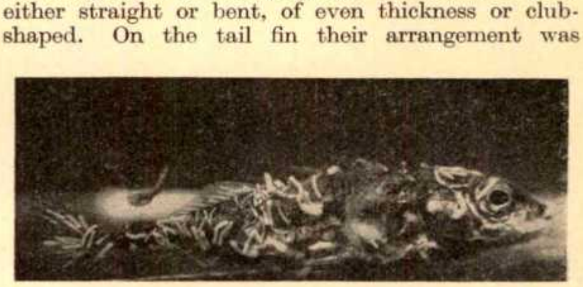

Fig. 1. Male stickleback infected with *Dermocystidium gasterostei* n.sp. Note radial arrangement of cysts on the tail, also one cyst crossing the rt. cornea (× *c.* 1·5)

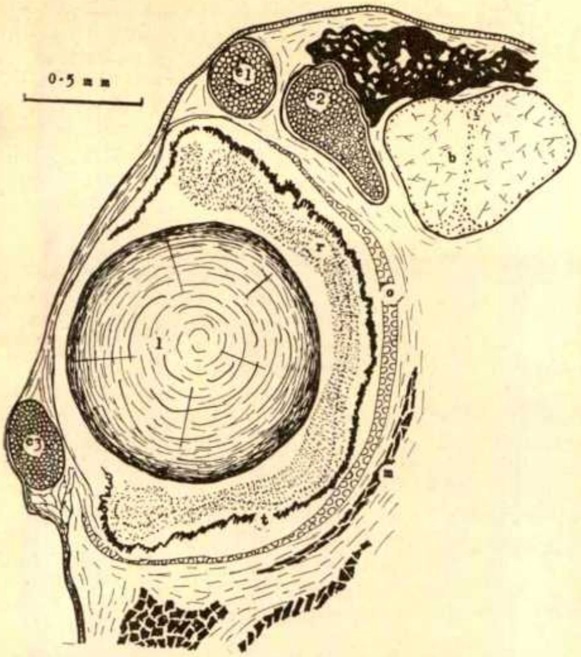

Fig. 2. *Gasterosteus aculeatus*. Transverse section through the skull showing cysts filled with spores of *Dermocystidium gasterostei* n.sp.
b, Brain; c_1, cyst in sub-cutis; c_2, cyst in the angle between frontal bone, brain and orbit; c_3, cyst in the cornea; *l*, lens; *m*, ocular muscle; *o*, orbital cartilage; *r*, retina; *t*, tapetum

fan-shaped, following the direction of the tail bones. No cysts were found on the gills or in the visceral organs. In several specimens cysts were seen in the cornea of the eye, some of them were also found deeply embedded between the skull bones, close to the brain capsule (Fig. 2). Although the cysts were numerous even on small fish, they did not seem to inconvenience the sticklebacks unduly. The fact that some of them died soon after arrival may be explained by the effect of transport; those which survived the first few days were seen to feed quite normally in the laboratory aquarium.

The following sporozoan parasites have previously been found to occur in *Gasterosteus: Glugea anomala* Moniez (= *G. microspora* Thél. in the sub-cutis, *Henneguya media* Thél., *H. brevis* Thél. and *Sphaerospora elegans* Thél. in the kidney and the ovary, and *Coccidium gasterostei* Thél.) in the liver. Of these parasites only *Glugea anomala* M. produces dermal cysts which may be deeply embedded but which are always spherical. The appearance of the diseased fish and of the parasite described here differs widely from any formerly described from *Gasterosteus*.

The contents of the cysts were not uniform. In one and the same fish cysts in various stages of development could be observed. The staining reactions of the cyst wall was always that of the surrounding connective tissue. The cyst wall must therefore be regarded as a product of the host. Yet, in one and the same fish some cysts could be seen with walls of considerable thickness while other agglomerations of spores were either surrounded by an extremely thin cyst wall or by none at all (Fig. 4). Nor can these various developments of the cyst wall be paralleled by the general development of the cyst contents. Some cysts, containing young stages of spores, had well-developed walls, while others, containing mature spores, had thin walls or none at all. The relation of cyst maturity and cyst wall is unpredictable and appears to be haphazard, nor is the development of the wall related to the site in which the cyst happens to develop. Cysts with very differently developed walls could be seen to lie side by side (Fig. 4). The earliest stages of development in this material were represented by cysts filled with an amorphous protoplasmic mass in which chromatinic granules were more or less evenly distributed (Fig. 5*a*). These chromatinic granules gradually coalesce to form nuclei, splitting up the protoplasmic mass in the process (Fig. 5*b*). Gradually the whole protoplasmic mass splits up into spherical portions of between 8–10μ diameter each of which contains several larger and many smaller chromatinic granules (Fig. 5*c*). These spherical or ovoid bodies are surrounded by an extremely thin cell wall. They

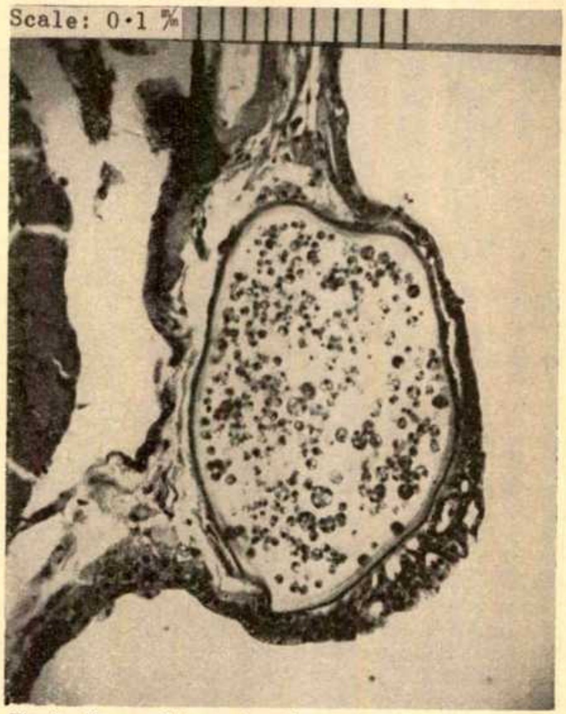

Fig. 3. *Dermocystidium gasterostei* n.sp. Typical cyst with cyst wall and well-developed spores in the sub-cutis of a stickleback. Note the unequal size of the spores

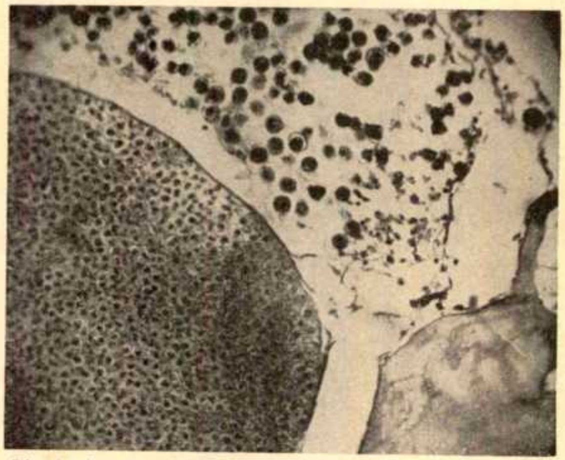

Fig. 4. *Dermocystidium gasterostei* n.sp. Two agglomerations of spores in different stages of development from the head of the stickleback (*Gasterosteus aculeatus* L.). Neither of these 'cysts' is surrounded by the typical cyst wall. (Hæmatoxylin and eosin, × *c*. 35)

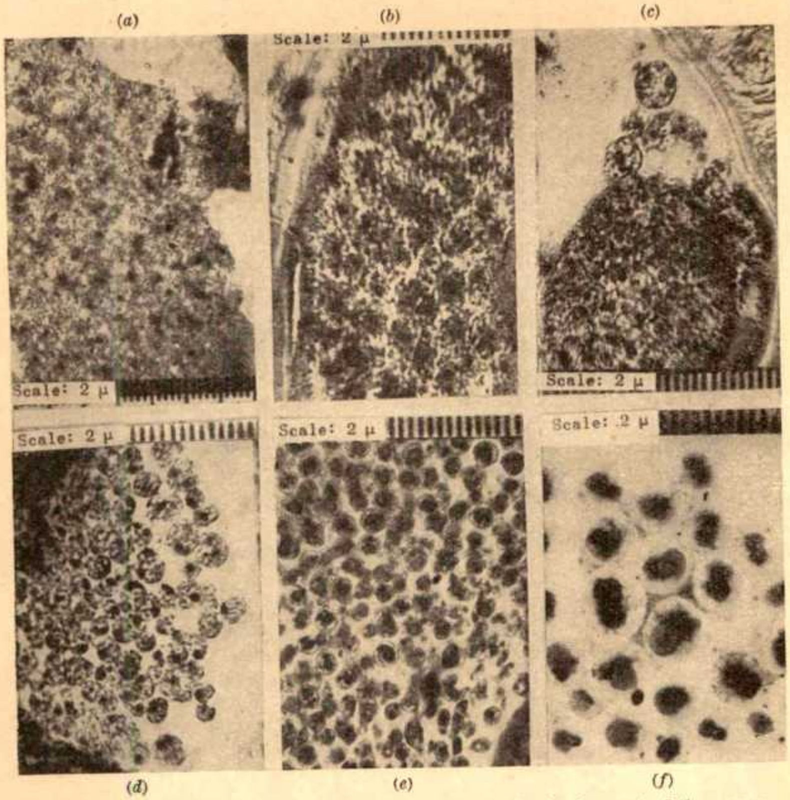

Fig. 5. *Dermocystidium gasterostei* n.sp. Six stages in the development of the spores. (*a*), Plasmodium, first concentration of chromatinic masses; (*b*) concentration of cytoplasm around developing nuclei; (*c*) separation of spherical multinuclear portions (schizonts); (*d*) further division of schizonts which become uninuclear; (*e*) appearance of spore membrane and acidophile inclusion body; (*f*) spores almost mature but adhering to one another by their sticky membrane

divide in turn, transforming themselves gradually into spores of 3–4μ diameter. They are then seen to have a definite cell wall, a nucleus, cytoplasm and an inclusion body which takes up most of the cell content.

The cell wall is, on the outer side, covered with a sticky substance in virtue of which the spores stick to one another and also adhere to the skin of the fish when the cyst is ruptured. The inclusion body is so large that it displaces the cytoplasm and the nucleus to one side towards the periphery of the cell where it can be seen in the shape of a bowl, or, in lateral view, as a crescent. When fully developed, the cell wall gives a positive periodic acid–Schiff reaction. It can be shown, with the aid of this reaction, that the individual spores within one cyst do not all develop at the same rate. Some become completely opaque because of the heavily +ve periodic acid–Schiff-capsule while others maintain graded degrees of transparency. The final size of the spores is not uniform but varies between 3 and 5μ. It has not been possible to demonstrate that these spores have a lid. The development described here follows the course of a primitive asexual reproduction. One could easily label the various stages as plasmodium, sporont, sporoblast and spore analogous to the terms used in the more highly developed sporozoa but little would be gained by applying this nomenclature to a process the different stages of which blend into one another so imperceptively that it would be impossible to say when one is abandoned and the next stage reached. The most characteristic feature of these spores is undoubtedly the very large inclusion body which, like the cell wall, always gives a positive periodic acid–Schiff reaction. It contains presumably nutritive material which can be utilized when the spore has entered a new host.

Several years of observation will be required to show whether the appearance of this parasite is always linked with the early months of the year and whether it is, in Britain, confined to *Gasterosteus*. Regarding the life-cycle of these spores it has been suggested for *Dermocystidium percae*[2] that the spores, after falling to the bottom of the pond and over-wintering there, might be taken up by Copepods and spend an intermediate stage in *Daphnia* or *Cyclops*. An unsuccessful search was made for both these crustaceans in the waters where the sticklebacks were taken. Also, the assumption of an intermediate host does not really seem necessary where sticklebacks are concerned. These are among the most pugnacious of fish, well known to bite each other viciously, particularly during the breeding season. It would be easy for the attacker to rupture a cyst and to fill its mouth with spores. It is, on the other hand, difficult to visualize *Daphnia* or *Cyclops* picking up and swallowing anything as large and sticky as these spores, which, if they fell to the bottom of a pond, would immediately be covered by the mud. It must further be considered that the cyst-covered fish appeared at a time of the year too early for the appearance of Copepods, which only hatch with the advent of warmer weather.

The parasite described here is morphologically very similar to *Dermocystidium percae* R–K, with the difference that the latter was said to have spores with a lid, whereas no lid could be seen in the spores from sticklebacks. Also, the cysts found on perch were all lying on the surface or in the subcutis whereas in *Gasterosteus* some penetrated deeply into the skull. So far the parasite has been found exclusively in two species of *Gasterosteus* and on no other fish, particularly not on perch, although these inhabited the same waters in which the sticklebacks were found.

For these reasons the parasite is regarded as a new species and is named *Dermocystidium gasterostei* n.sp. with the characters described. Host: *Gasterosteus aculeatus* L. and *G. pungitius* L.; locality: Newdigate, Surrey, England; type material in my collection and at the Department of Parasitology, Imperial College of Science and Technology, Sunninghill.

I thank Dr. J. R. Baker, London School of Hygiene and Tropical Medicine, for his advice.

USE OF 'SEASONAL' REGRESSIONS IN MEASURING FEED INTAKE OF GRAZING ANIMALS

By L. J. LAMBOURNE* and T. F. REARDON

C.S.I.R.O. Pastoral Research Laboratory, Armidale, New South Wales

RELATIONSHIPS established with pen-fed sheep or cattle between herbage digestibility or feed-to-fæces ratio and either fæcal nitrogen or fæcal 'chromogens' are being increasingly used for measuring the feed intake of grazing animals, but the regression lines vary according to the time of the year at which the herbage is cut[1,2].

A series of digestion trials was carried out here in spring 1961 to test the hypothesis that such variation might result from changes in the relative proportions of leaf and stem in the herbage eaten.

The pasture of ryegrass (*Lolium perenne*), *Phalaris tuberosa* and white clover (*Trifolium repens*) was about 6 in. high and predominantly leafy at the start and about 15–18 in. high and in early seed head at the end of the series of four trials.

Pasture was cut every second day at a height of 1–2 in. and chaffed, this material being referred to afterwards as 'whole herbage'. A portion of it was winnowed by dropping it through the air stream from an electric fan in a horizontal tunnel. Grass leaf laminæ tended to be blown out and were collected as the 'leaf' fraction. Stem and leaf-sheath tended to remain and were collected as the 'stem' fraction. Clover stem tended to remain in the 'stem' fraction and clover leaflets were evenly divided between the two fractions. The process thus gave 'stem'-rich and 'leaf'-rich fractions rather than complete separation.

Table 1. MORPHOLOGICAL COMPOSITION OF FEED OFFERED

Composition of feed offered (dry matter basis)*

		Feed type					
		Whole herbage		Leaf		Stem	
Trial	Morphological components	%	Sheep	%	Sheep	%	Sheep
1 (7.10.61–16.10.61)	Grass lamina	62	*A* and *B*	72	*C*	58	*D*
	Clover leaf	17		22		27	
	Stem and leaf sheath	19		6		16	
2 (23.10.61–1.11.61)	Grass lamina	63	*A* and *B*	78	*D*	29	*C*
	Clover leaf	15		14		17	
	Stem and leaf sheath	22		7		54	
3 (6.11.61–15.11.61)	Grass lamina	37	*B*	73	*D*	29	*C*
	Clover leaf	37		12		7	
	Stem and leaf sheath	25		14		64	
4 (8.12.61–17.12.61)	Grass lamina	43	*A* and *B*	63	*C*	10	*D*
	Clover leaf	4		4		0	
	Stem and leaf sheath	34		15		64	

* Extraneous material (weeds, seed heads, etc.) was 1–2 per cent except in trial 4, when it amounted to about 20 per cent.

Four Merino wethers in metabolism cages were used throughout the experiment except in trial 3, when sheep *A* was not used. In each digestion trial, two sheep were fed whole herbage, one was fed the 'stem' and one the 'leaf' fraction. Dried samples of each type of feed were bulked and later hand-sorted into morphological components. Table 1 gives details of the feed offered.

Table 2. FEED INTAKE AND DIGESTIBILITY AND FÆCAL NITROGEN AND 'CHROMOGEN' CONCENTRATIONS

		Trial No.			
	Feed	1	2	3	4
Dry matter eaten (g/day)	Whole herbage	281, 235	495, 476	–, 617	381, 397
	'Leaf'	378	535	862	396
	'Stem'	249	444	740	387
Organic matter digestibility (per cent)	Whole herbage	84·5, 84·3	81·0, 80·5	–, 80·1	68·9, 71·0
	'Leaf'	84·0	79·6	73·8	70·2
	'Stem'	86·9	82·8	75·4	67·6
N in fæces (g/100 g organic matter)	Whole herbage	4·32, 4·75	3·59, 3·71	–, 3·06	2·27, 2·57
	'Leaf'	4·26	3·77	3·16	2·88
	'Stem'	4·14	3·32	3·06	2·01
'Chromogen' concentration*	Whole herbage	1090, 1040	730, 710	–, 420	395, 230
	'Leaf'	1125	840	335	585
	'Stem'	890	790	345	270

* [(Optical density × volume of extract in ml.) divided by (weight organic matter extracted)] × 1/10

Table 2 shows the feed consumption, organic matter digestibility and concentrations of nitrogen (dried fæces) and of 'chromogens' (frozen fæces). Feed rejection was 11 per cent or less in all cases except for sheep *A* trial 1 (28 per cent) and sheep *B* trial 3 (30 per cent), both fed on whole herbage.

In Fig. 1 the relationships of intake factor (feed organic matter divided by fæcal organic matter) to fæcal nitrogen concentration for whole herbage, 'leaf', and 'stem' are shown. The regression lines for 'leaf' and 'stem' differ significantly in elevation. The difference (about 1·7 units of intake factor) exceeds the difference between 'summer' and 'winter' lines (0·7 units) found in this Laboratory[3], and exceeds also the difference between Minson and Kemp's[1] June and November lines (ranging from about 0·7 to 1·7 units of intake factor).

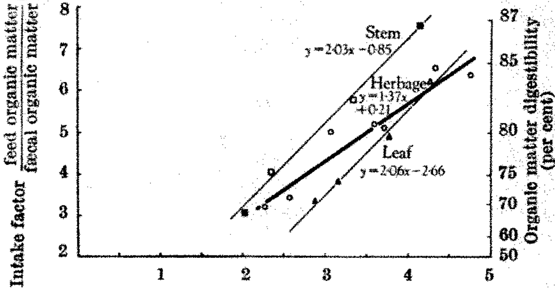

Fig. 1. Regressions of intake factor (feed organic matter + fæcal organic matter) on N per cent of fæcal organic matter for whole herbage (○, sheep *A* and *B*), 'leaf' (△, sheep *C*, ▲, sheep *D*), and 'stem' (□, sheep *C*, ■, sheep *D*). N per cent determined by Kjeldahl digestion on dried samples

Values for whole herbage fell generally between the 'leaf' and 'stem' lines.

In Fig. 2 the relationships between intake factor and fæcal 'chromogens' for whole herbage, 'leaf' and 'stem' are shown. General features similar to Fig. 1 are evident but the difference between 'leaf' and

---

* Present address: Grassland Research Institute, Hurley, near Maidenhead, Berks, England.

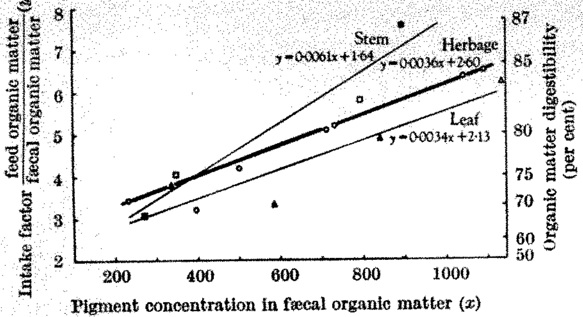

Fig. 2. Regressions of intake factor (feed organic matter + fæcal organic matter) on fæcal pigment concentration ('chromogens') for herbage (○, sheep *A* and *B*), 'leaf' (△, sheep *C*, ▲, sheep *D*), and 'stem' (□, sheep *C*, ■, sheep *D*). Pigments determined as optical density of 85 per cent acetone extract of frozen fæces

'stem' lines is not statistically significant. Whole herbage values again tended to be intermediate.

Changes in the position of regression lines of digestibility (or of feed-to-fæces ratio) on fæcal nitrogen or 'chromogens' have thus been brought about solely by feeding 'leaf'-rich and 'stem'-rich fractions.

The digestible material of 'leaf' was presumably associated with much more chloroplast pigment and protein, and that of 'stem' with relatively greater amounts of soluble and digestible carbohydrates[4] but with less chloroplast material.

In these trials the digestibility of 'stem' was initially higher than that of 'leaf' but fell more rapidly after ear emergence. This confirms and helps to explain the plateau of digestibility observed by Minson, Raymond and Harris[5] despite a big reduction in the percentage of leaf lamina.

Digestion trials with the cattle pasture[6] often yield higher values of intake factor for a given fæcal nitrogen percentage than do trials with shorter, leafy, sheep pasture[3,7,8]. This may perhaps now be ascribed to the higher proportion of 'stem' material in the taller herbage.

These trials clearly indicate that the 'leaf' and 'stem' herbages have intrinsically different digestibility patterns and fæcal index regressions, and that 'seasonal' variation in regressions may result primarily from variations in leaf/stem ratio following the cycle of vegetative and reproductive growth. If this is so, the regression appropriate to a particular grazing experiment cannot be determined by calendar date alone. The prime requirement is rather that the regression should be based on herbage morphologically similar to that eaten in the experiment even if they are not from the same sward or the same month.

There is good evidence[9] that grazing sheep tend to select leafy herbage rather than stem. The more conservative estimates of herbage intake obtained by using the 'leaf' type regressions are therefore preferable for sheep experiments.

VIRUSES ASSOCIATED WITH A DIE-BACK DISEASE OF CULTIVATED MUSHROOM

By M. HOLLINGS

Glasshouse Crops Research Institute, Littlehampton, Sussex

ALTHOUGH conclusive evidence is lacking, viruses have been suggested as the causes of certain abnormalities of fungi from which no visible pathogens could be isolated, such as the transmissible disease[1] of *Helminthosporium victoriae* Meehan and Murphy, and of several Agaricaceae[2]. Jinks[3], however, considered the 'vegetative death' in *Aspergillus glaucus* to be caused by lethal suppressive cytoplasm.

There is a group of cultivated mushroom (*Agaricus bisporus* (J. Lange) Pilát 1951) disorders that includes watery stipe, La France, brown, mummy and *X*-diseases, the cause of which is uncertain and the symptoms of which have in common the degeneration of the mycelium, various sporophore abnormalities and, often, waterlogging of the tissues, especially the stipe[4].

Although waterlogged stipes can result from cultural conditions[5], Gandy demonstrated that they are sometimes associated with a transmissible disease[6] the characteristic symptom of which is complete mycelial degeneration. This disease was transmitted to healthy mushrooms not only by adding infected mushroom compost or agar culture of diseased mycelium to trays containing healthy spawn but also *in vitro*, when disks cut from agar cultures of normal mycelium were inoculated by dipping in a suspension of macerated diseased cultures containing viable cells[7]. Moreover, when infected agar cultures in Petri dishes were grown at 33° C for two weeks, and hyphal tips then transferred to new medium at 25° C, normal growth resulted. Similar cultures maintained throughout at 25° C remained diseased[7].

In the absence of a visible pathogen, these results suggested a virus disease, and preliminary experiments[8] showed that purified preparations from diseased, but not from healthy, sporophores contained virus-like 'spherical' particles (approximately 25 mμ diameter), produced a characteristic light-scattering zone in density gradient centrifugation, and caused infection when injected by hypodermic needle into developing sporophores at the first flush stage. Infection of the mycelium in inoculated trays was later confirmed by transmission tests in Petri dish cultures, and the disease was reproduced by further inoculation of healthy mushrooms in trays. The most characteristic symptom of the disease was not the waterlogging of the stipes but the rapid mycelial degeneration, and the way cropping ceased; the name 'die-back' was therefore given to distinguish it from other conditions.

In the present work, cell-free preparations of mushroom tissues have been examined for infectivity, serological activity, formation of zones in density gradient centrifugation, and the presence of virus-like particles. Material for study was at first collected from outbreaks of disease on mushroom farms, but was later obtained by routine inoculation of trays of healthy mushroom spawn with infective compost. Infection developed much more rapidly in mushroom trays containing healthy spawn when inoculated with infective mycelium or compost than when purified virus preparations were injected into the first-formed sporophores. Thus, preparations from sporophores 13 days after inoculation of the tray with infective mycelium had a high virus content, whereas those from trays inoculated by injection of the sporophores at the 'button' stage yielded no detectable virus in a similar time. Inocula were checked for infectivity and standard reaction by the Petri dish culture test[7].

Initially, virus purification was attempted by mincing sporophores showing typical symptoms of watery stipe in 1·25 × wt./vol. of 0·05 M buffer ($Na_2HPO_4 - KH_2PO_4$, *p*H 7·6) containing 0·1 per cent thioglycollic acid. *n*-Butanol was added drop by drop to 8·5 per cent final concentration, and coagulated matter removed by slow-speed centrifugation. The supernatant fluid was filtered and centrifuged to sediment the virus (30,000 r.p.m. for 120 min in the *R*.30 rotor of a Spinco model *L* preparative centrifuge), the pellets re-suspended in one-twentieth original volume of 0·03 M phosphate buffer, and insoluble matter removed by brief centrifugation. Although such preparations were infective and contained characteristic virus-like particles, they still contained much unwanted mushroom material, which produced two non-specific zones in density gradient centrifugation: a broad upper layer, intense creamy white in colour, extending from 10 to 22 per cent, and a fainter creamy grey zone at 31–36 per cent levels, in sucrose gradient columns[9] after centrifugation for 120 min at 25,000 r.p.m. in the Spinco *R* 25 rotor. Preparations from both healthy and diseased mushrooms gave these two zones, but a specific, faint bluish-grey zone at the 28–30 per cent sucrose-level occurred only with diseased material, and the typical 'spherical' particles, 25 mμ diameter, were concentrated here.

Serum obtained after infective preparations had been injected into rabbits reacted as well with healthy as with diseased mushroom preparations; the double reaction lines in gel-diffusion slide tests[10] were derived from antigens that were confined to the top, creamy-white zone in the gradient tubes. The addition of formaldehyde to 0·2 per cent to the antigen preparations before injection made no apparent difference to the performance of the serum, although this treatment had enabled a specific serum to be prepared against a virus of celery[11].

Different kinds and concentrations of buffer solutions were then compared in efforts to improve the virus purification. No benefit was obtained by using chelating agents, such as ethylenediamine tetraacetic acid, but substitution of borate buffer ($H_3BO_3 - Na_2B_4O_7$, *p*H 7·6) containing thioglycollic acid for the phosphate buffer gave final preparations containing more virus and without the unwanted mushroom constituents. With other plant viruses, the intensity of specific zones in density gradients has given a measure of the virus concentration, and at first provided the only means of assay of mushroom preparations. Later, the serological titre was used. A concentration of 0·05 M borate buffer was better than either 0·5 M or 0·1 M, and preparations made at laboratory temperatures (about 18° C) were better than those made at about 4° C. Using 0·05 M buffer with the butanol extraction method previously described, mushroom stipes were a much better source of virus than the pileus, and the symptomless sporophores first produced after infection better than later-formed ones showing typical symptoms. Older sporophores not only contained less virus, but also more of the unwanted substances that hampered virus purification. Re-suspension of the final pellets in 0·03 M phosphate buffer was better than in equivalent borate buffer. The virus obtained from 50 g of infected sporophore stipes was normally dispersed in 1 ml. of buffer; 0·25–0·5 ml. of a good preparation gave a clearly defined zone in density gradient centrifugation, and had a titre of 1/64 in serological gel-diffusion slide tests. The yield of virus from different batches of material varied considerably.

Petri dish cultures of diseased mycelium grow extremely slowly, and the small quantity of material produced has never been adequate for virus purification. Attempts to precipitate virus from clarified mushroom juice by ammonium sulphate added to one-third saturation were also unsatisfactory, because copious amounts of mushroom constituents remained; nevertheless, virus could be detected serologically in gel-diffusion tests with such preparations.

For electron microscope examination, virus preparations were stained with potassium phosphotungstate; the measured particle sizes are therefore smaller than would be obtained with shadowed mounts. The routine supply of material contained not only a few 'spherical' particles of the type first seen (25 mμ diameter), but also more numerous, larger particles of approximately 29 mμ diameter, and many elongated particles with rounded ends (size about 19 × 50 mμ) which can be described as 'sausage shaped' or 'bacilliform' (Fig. 1). The shape of the particles is of interest: the 29 mμ ones are angular, usually hexagonal, and resemble some of the soil-borne ringspot

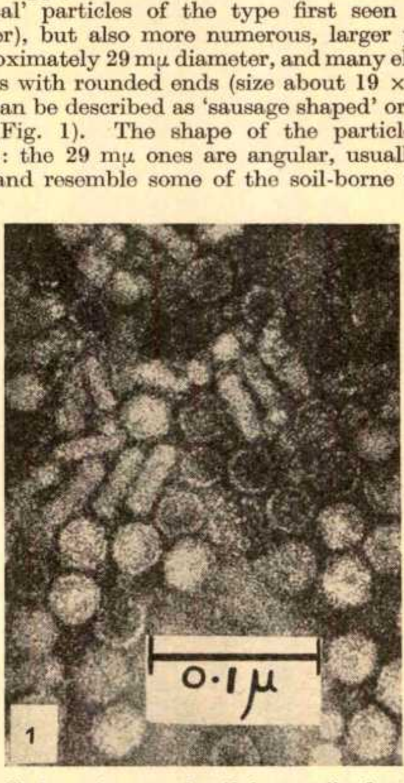

Fig. 1. Electron micrograph of purified preparation from infected mushroom

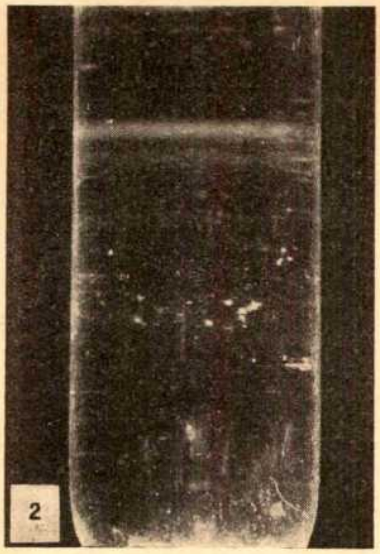

Fig. 2. Specific light scattering zones produced by mushroom virus preparations in density gradient centrifugation approaching equilibrium

viruses of similar size. The only other plant virus with a bacilliform particle known at present is lucerne mosaic[12], where particles 18 mμ diameter occurred in lengths of 36, 48 and 58 mμ.

For some weeks, virus was found only in sporophores from inoculated trays, preparations from uninoculated trays giving negative reactions in all tests. Later, however, infection spread to one of the uninoculated trays, for preparations from symptomless sporophores in this tray produced characteristic zones in density gradient centrifugation, and reacted strongly with a specific antiserum. Electron micrograms, however, showed only the 29 mμ hexagonal particles, suggesting that only one virus had been transferred. Unfortunately, the tray concerned had by this time ceased cropping and been destroyed.

When examined in the Spinco model *E* analytical centrifuge, preparations containing the three types of virus particle gave 3 peaks, whereas those containing only the 29 mμ particles had only 2 peaks—S_{20} = 130 and 74—so that the other peak ($S_{20} = 96$) probably represents the elongated particles, rather than the very few 25 mμ 'spheres'. The peak at 74 may consist of 'empty' particles of the 29 mμ virus, for such 'empty' particles were seen in electron micrograms of that preparation. I do not know whether the elongated particles were present in my early material and were lost in the purification, or what part each type of particle plays in the disease symptoms. The ultra-violet absorption spectrum of preparations containing only the 29 mμ particles showed a maximum at 260 mμ, with the ratio of 1·32 for the optical density at 260/280 mμ.

Density gradient centrifugation of virus preparations, in either sucrose/0·03 M borate or sucrose/0·03 M phosphate buffer, *p*H 7·6, gave either a single or a double zone, of the characteristic blue colour seen with many plant viruses; the unspecific cream-coloured zones produced with phosphate buffer preparations were absent from those made with the borate buffer method (Fig. 2).

After 30 min centrifugation at 25,000 r.p.m. in the *R* 25 rotor in rate-zone[13] gradients (4, 7, 7 and 7 ml. respectively of 10, 20, 30 and 40 per cent sucrose solutions in 0·03 M phosphate buffer), the characteristic zone was at the 14–15 or 15–16 per cent sucrose-level, depending on variation in shape of individual centrifuge tubes. A second, less intense zone sometimes occurred at 12–13 per cent level. There was no difference between the levels of the zones formed in sucrose/borate buffer and sucrose/phosphate buffer gradients, although the reaction between sucrose and borate buffer is stated to decrease the viscosity of the mixture. The 29 mμ and the elongated particles were both present in the specific zones in density gradient tubes; although the two zones sometimes produced were carefully withdrawn by hypodermic needle inserted through the tube wall while the tube was strongly illuminated from above, both upper and lower zones contained the two types of particle. The sedimentation coefficient of a solvated particle is a function of its size, shape and density[14], and because the calculated volumes of the 29 mμ hexagonal particle and the elongated particle are similar (12,770 and 12,435 $m\mu^3$ respectively), they might be expected to sediment at similar rates in rate-zonal centrifugation, and thus not be readily separable in this way.

The formation of double zones is of interest, but none of the explanations so far put forward is entirely satisfactory. Electron microscope examination of the zones did not support the possibility that the upper zone was composed of 'empty' particles, similar to the 'top component' of turnip yellow mosaic virus[15], for empty particles occurred in both zones. Matthews[16] reported multiple zones when apparently homogeneous preparations of turnip yellow mosaic virus were centrifuged in gradients of cæsium chloride, and suggested that these zones comprised virus particles in different stages of assembly. However, some preparations of mushroom virus have consistently given two zones; others, which gave one zone in tests made shortly after purification, produced two zones when they had been stored at 0° C for about 3 weeks. Nor is the suggestion that some particles might aggregate into dimers satisfactory; this might explain two zones in rate-zonal centrifugation, where sedimentation is influenced by the effective size of the particle, but not two zones in sedimentation approaching equilibrium. That the two zones are formed by different types of virus particle is also improbable, for electron microscopy showed that each zone contained the 29 mμ and the elongated particles. Even allowing for failure to withdraw the zones from the gradient column completely separate from each other, preparations containing more than one type of particle have given one zone on some occasions and two zones at other times. Also, the preparations from the naturally infected tray contained only 29 mμ particles, yet gave two zones.

An apparently similar problem has arisen in work with some plant viruses such as pelargonium leaf curl[17], where 2, 3 or 4 zones may occur with different preparations from the same source of virus, and in which results suggest combination of the virus particle during or after purification with some substance that increases the sedimentation-rate and effective density, and impairs the ability of the virus to multiply; for it is the lower zones with pelargonium leaf curl virus, unlike turnip yellow mosaic virus, which behave abnormally in infectivity tests, although serologically indistinguishable from the typical form of the virus.

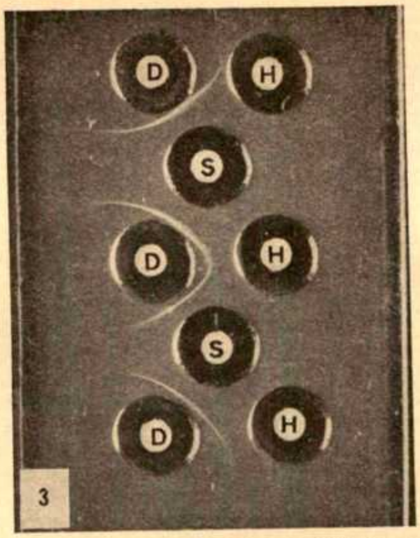

Fig. 3. Gel-diffusion slide serological test. Wells *D* contain preparation from diseased, wells *H* from healthy, mushroom. Virus antiserum in wells *S*

Preparations containing numerous virus particles, but freed from the antigenic mushroom substances, could consistently be produced by the borate buffer–butanol method, and were used to prepare antisera. 1 ml. aliquots of infective preparations were emulsified with 1 ml. of Freund's complete adjuvant (Bacto) and injected intramuscularly into rabbits. Two injections were given, three weeks apart, and serum obtained 2½ weeks after the last injection. This serum reacted specifically with preparations from diseased, but not from healthy, mushrooms (Fig. 3). The antigen preparations contained all three types of particle, but these preparations gave only a single reaction line in gel-diffusion tests. This line was identical and continuous with that formed by the preparations containing only the 29-mμ particles. There is thus no evidence that the other particles were antigenic, although the 25-mμ particles were probably too few to elicit a detectable response in rabbits or in serological tests. The possibility cannot be excluded that the 25-mμ particles are a damaged or breakdown product of the 29-mμ ones, although there is no evidence for this.

The 19 × 50-mμ particles resemble those of lucerne mosaic virus, and tests were made for other similarities between them. However, the mushroom virus preparations did not react with antiserum to lucerne mosaic virus, nor did mushroom virus antiserum react with purified preparations of lucerne mosaic virus. Also, the density gradient zones obtained with preparations of lucerne mosaic virus differ from those of mushroom viruses. Inoculation by rubbing mushroom preparations on standard test plants susceptible to many plant viruses (including lucerne mosaic and the soil-borne ringspot viruses), such as *Chenopodium amaranticolor* Coste and Reyn., *Gomphrena globosa* L., *Nicotiana clevelandii* Gray, *N. glutinosa* L., *N. tabacum* L., *Phaseolus vulgaris* L. and *Tetragonia expansa* Murr., produced no symptoms.

The results reported here show that die-back disease of mushrooms is caused by one or more viruses, and can be transmitted by injection of cell-free preparations into healthy mushroom sporophores. Efforts to separate the viruses, the identification of the disease symptoms with each virus or viruses, and studies of the means of natural spread and epidemiology of the disease continue as part of the programme of this Institute.

I thank Dr. F. T. Last and Miss D. G. Gandy for growing and inoculating the mushrooms, and Mr. H. L. Nixon, of Rothamsted Experimental Station, for the electron micrograms and the sedimentation constants.

APOCRINE SWEAT GLANDS OF THE SCROTUM OF THE RAM

By G. M. H. WAITES and J. K. VOGLMAYR

C.S.I.R.O. Division of Animal Physiology, Ian Clunies Ross Animal Research Laboratory, Prospect, New South Wales

EVAPORATION from the skin of sheep is believed to be of secondary thermo-regulatory importance when compared with evaporative cooling from the respiratory tract[1-3]. Although this may be true for the densely fleeced body, it is possible that the more lightly covered skin of the extremities plays an important part in temperature regulation, as the considerable regional differences in the number and volume of the sweat glands in Merino rams would suggest. The glands in the skin of the peripheral parts of the legs are larger and more numerous than in mid-side skin, while in the scrotum they are of considerably greater volume than anywhere else examined (Fig. 1). The sweat glands in the scrotum of rams are of comparable volume with the sweat glands of the ox[4,5] in which sweating is thought to be a major channel of heat loss.

The functional properties of these large apocrine sweat glands were examined by enclosing the scrotum of Merino and Border Leicester × Merino rams in an

insulated chamber, the wall temperature of which could be changed and through which dried air at controlled temperatures was circulated in a closed circuit. When the air and wall temperatures were raised from 20° C to 42° C, the temperature of the scrotal skin, recorded by 38 s.w.g. thermocouples, rose rapidly from 30° to 34° C into the range 35°–37° C. The first expulsion of sweat then occurred and was indicated by a sudden increase in the humidity of the air leaving the chamber and passing over a recording dew cell (Fig. 2). A wool-covered patch of scrotal skin was warmer than adjacent bare skin when the air was cool but the temperature of bare skin rose above that of wool-covered skin when the air was heated. This is presumably due to the insulating properties of wool and also to the protection it gives against radiant heat[6] emitted by the chamber wall. Quick rises of up to 1·5° C in the temperature of wool-covered skin coincided with the appearance of water vapour in the chamber air and were followed by more prolonged cooling of the skin. The warming was presumably due to an exothermic reaction of sweat with wool[7,8], for this was not observed when the skin was shaved. Instead, bare skin always quickly cooled by up to 2·6° C, the first expulsion of sweat usually producing the greatest reduction in temperature. Thus, as a result of the same sweat discharge, a patch of wool-covered skin on the scrotum could be warming while an adjacent area of shaved skin was cooling (Fig. 2). Even so, the temperature of skin under wool never rose above that of adjacent bare skin during heating. As the skin dried following each discharge, surface temperature rose again; the warming-up was delayed and slower when wool was present (Fig. 2).

All or a constant proportion of the glands appear to take part in each discharge because thermocouples applied to different areas of the scrotum record similar changes of skin temperature. Mass spontaneous discharges of the sweat glands of mid-side skin of Welsh Mountain sheep have been described when the whole animal was exposed to heat (42° C), but never more frequently than once every ¾–1 h (ref. 7). The expulsion of sweat by the glands of the scrotum occurred at 2–17-min intervals in seven rams, but in one ram the intervals were characteristically longer.

When the scrotum of fully fleeced rams is locally warmed to above 36° C, respiratory rate increases and hypothermia usually follows as a result of the increased evaporative cooling[9,10]. In the experiments reported here, temperatures in the rectum and in free-flowing blood in the carotid artery either remained unaltered or, more usually, fell by up to 1·4° C/h when the scrotum was warmed (Fig. 2). The sweat discharges continued whether body temperatures were falling or steady. The reflex polypnoea was often interrupted during a sweat gland discharge (Fig. 2) and the reduction in breathing rate was often completed before the skin started to cool. As similar changes in respiratory rate were observed in fleece-covered sheep when an exothermic rise of skin temperature occurred on sweating[7], it appears that the effect is unrelated to skin temperature and could be central in origin. All sweat gland discharges by the scrotum in response to heating were abolished by locally blocking the superior perineal nerves which carry sensory fibres from the scrotum. Thus, although central hyperthermia may facilitate sweating in sheep as in other species, cutaneous afferent stimulation alone is sufficient to bring about sweating from the scrotum.

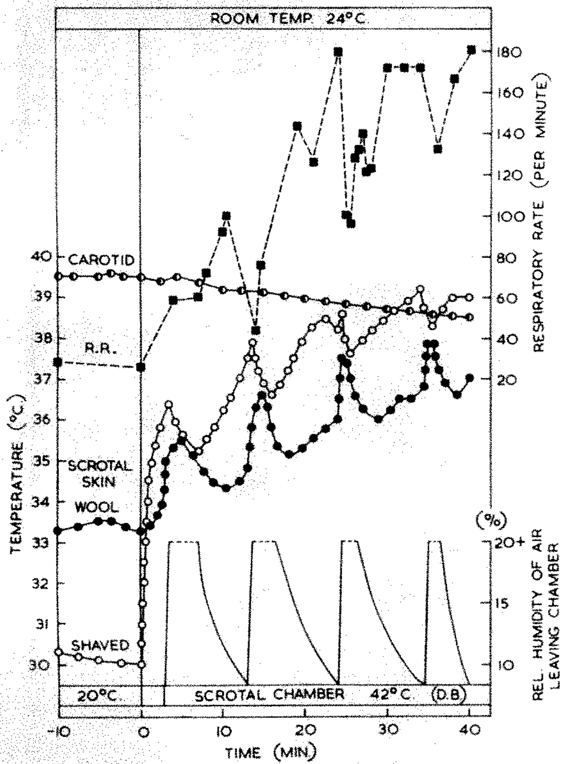

Fig. 2. Record of four spontaneous discharges of sweat from the scrotum of a ram in response to local warming and their effect on the temperature of shaved (○) and wool-covered (●) scrotal skin and on respiratory rate (■). Carotid record from a thermocouple inserted through a hypodermic needle into the artery in a fold of skin

The discharges could be provoked by single intravenous injections of adrenaline and 1-noradrenaline (1–2 μg/kg) into rams in which the scrotal skin was warmed to a temperature just below that at which spontaneous discharges occur. The glands responded to a second dose within 8 min of the first, unlike the mid-side glands, which have been shown to be refractory to adrenaline for at least ½ h (ref. 7). Bilateral adrenalectomy with supporting injections of cortisone acetate (0·5 mg/kg) and deoxycorticosterone acetate (0·05–0·10 mg/kg) did not abolish the sweat discharges in response to a heat stimulus. However, after adrenalectomy the interval between the application of heat to the scrotum and the first discharge was increased and this interval was again reduced by an intravenous infusion of 1 μg adrenaline/kg/min. It is clear that the expulsion of sweat by the glands of the scrotum in response to a local heat stimulus is under neural control although the appearance of the normal pattern of discharges appears to require normal adrenal function.

The fluid that evaporated from the scrotum during the experiments was collected by drying the circulating air in cylinders containing calcium chloride. There was always approximately a three-fold increase in fluid produced by scrotal skin when air temperature was raised from 20°–26° C to 40°–45° C. Both basal and maximal values obtained from individual rams were greater when the tests were made in the summer months (October–April) than in the winter (June–September), and must represent a seasonal variation in both insensible and sensible fluid loss from the scrotum. Maximal fluid production in the winter was 72–153 $g/m^2/h$ and increased to 134–208 $g/m^2/h$ during the summer. This agrees with histological evidence that sweat glands in body skin are larger in summer months[11].

The evidence presented supports the view that, in sheep, sweating is important to the regulation of the temperature of peripheral regions, especially the scrotum, and provides information about the mechanism of sweat released by apocrine glands, about which little is known[12].

We thank Mr. W. H. Clarke and the Histology Section of this Laboratory for assistance with the preparation and staining of the skin samples.

PROTEIN BODIES AND PROTEIN SYNTHESIS IN DEVELOPING WHEAT ENDOSPERM

By DR. JANET S. D. GRAHAM, A. C. JENNINGS, PROF. R. K. MORTON, B. A. PALK and J. K. RAISON

Department of Agricultural Chemistry, Waite Agricultural Research Institute, University of Adelaide

THE type and amount of protein have a marked influence on the baking quality of wheat flour. Hence we have examined several aspects of protein synthesis in developing grain of *Triticum vulgare* (varieties Gabo and Insignia) and of *Triticum durum* (variety Dural) grown under field conditions in Adelaide. This work has involved: (*a*) cytological studies with the electron microscope to determine the site of synthesis and the intra-cellular localization of the 'storage proteins'; (*b*) development of methods for the separation and identification of each of the major proteins of endosperm; (*c*) biochemical investigations related to the mechanism of protein synthesis.

These investigations were carried out with grain harvested at selected intervals from approximately the 5th to the 42nd day after the mean flowering date and immediately stored at − 15° C. Endosperm was obtained from the frozen grain either by hand dissection or by mechanical rolling. Mature grain was milled in a Bühler laboratory mill to 68 per cent extraction. For the cytological study, fresh grain or endosperm dissected out at room temperature was used as soon as possible after harvesting.

During development, both the fresh and dry weight per grain increase from about the 5th to the 35th day, after which the fresh weight declines, and the dry weight increases only slightly, until maturity at about the 45th day. During the period of rapid increase of protein in the endosperm there is a related increase in the amount of ribonucleic acid per grain, but there is little change in the amount of deoxyribonucleic acid per grain after about the 14th day. Thus development is mainly due to increase in dry weight of previously formed cells, and not due to cell division.

Electron microscopy of thin sections of developing wheat grain stained with either osmium tetroxide or potassium permanganate has been carried out at each of the times selected for chemical analyses, except that after about the 25th day so much starch is present that thin sections cannot be prepared. In addition to starch granules formed inside a distinctive 'plastid', the endosperm cells contain relatively large osmophilic bodies. Fig. 1 is typical, and shows that the bodies are contained within a definite lipoprotein membrane. In early stages of development there is a single body contained in the one membrane, but at later stages there are often four or more bodies. The bodies have now been isolated from wheat endosperm; due to their fragility the bodies are difficult to isolate in a relatively pure state, but good preparations contain about 85 per cent protein. Starch-gel electrophoresis patterns of these isolated bodies show that they contain predominantly slow-moving protein components; these patterns closely resemble those obtained for the acetic acid soluble proteins extracted from intact endosperm[1]. Radioisotope investigations have shown, even in short-term experiments, that accumulation of protein occurs in the bodies. As they increase in size and number during development, and as there is a rapid increase in the acetic acid soluble proteins during maturation of the endosperm[1], there is now good evidence that these bodies represent the 'storage proteins' of the wheat endosperm. Other workers[2-4] using light microscopy have described organelles in maize, sorghum and peanut, which on the basis of histochemical tests they have termed protein granules or protein bodies.

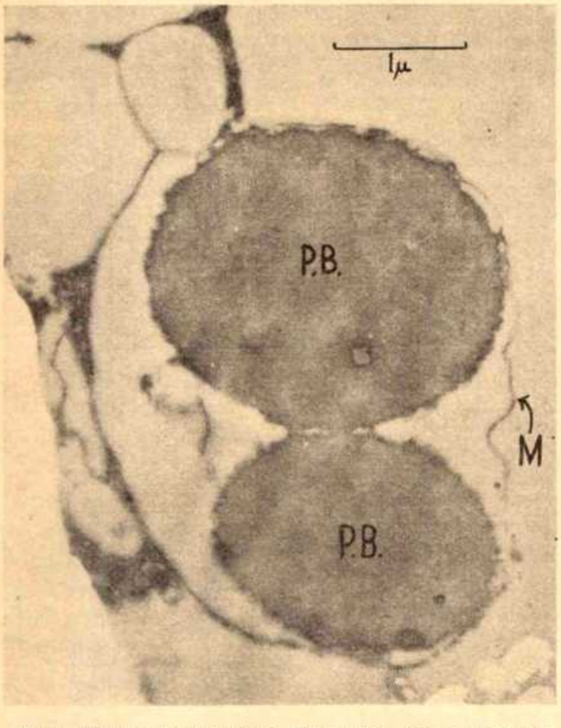

Fig. 1. Electron micrograph of a thin section of endosperm cells of grain of *Triticum durum* (variety Dural). The material was fixed and stained with osmium tetroxide for 1 h at *p*H 7·4 and embedded in methacrylate. Protein bodies (*PB*) and lipoprotein membrane of vacuolar structure enclosing bodies (*M*) are clearly shown

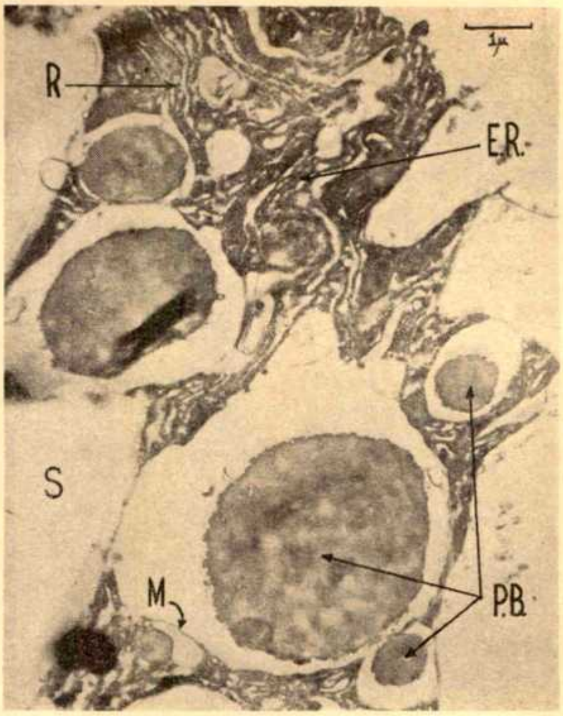

Fig. 2. Electron micrograph showing endoplasmic reticulum (*ER*), ribosomes (*R*) and starch (*S*). Otherwise the conditions are the same as in Fig. 1

In the grain endosperm, in contrast to the developing wheat root[5], the osmophilic ribosomes are arranged in an orderly fashion on parallel arrays of the lipoprotein membranes of the endoplasmic reticulum (Fig. 2). The structure of the endoplasmic reticulum is strikingly similar to that of the mammary gland which synthesizes and secretes casein particles. The 'storage proteins' are almost certainly formed on the ribosomes of the endoplasmic reticulum and afterwards they are secreted, not externally as in the mammary gland, but internally. It is thought that the formed proteins aggregate into the protein bodies within the surrounding lipoprotein membrane and are thus isolated from the remainder of the intracellular structures. It is therefore proposed that this process in plants be called 'internal secretion'. The 'protein bodies' thus appear to be localized in vacuolar structures of the endosperm cell. With increasing development these vacuolar structures containing protein bodies, and somewhat similar structures containing starch granules, occupy most of the expanding endosperm cell. The protein bodies themselves do not have a true limiting membrane but rather appear to be aggregates (as are casein particles), although, like nucleoli, protein bodies have a definite external boundary, the rupture of which may release the internal contents. However, they may be attached to the outer membrane of the vacuolar structure within which they are contained by a fine reticular network, seen in some electron micrographs. Quite frequently some of the vacuolar membrane is observed wrapped around the isolated bodies.

In addition to the biochemical studies of the isolated bodies extensive investigations have been carried out on the protein composition of the whole endosperm. This work has involved extraction of the proteins, fractionation of the extracts on modified cellulose columns[1], and characterization of the proteins by starch-gel electrophoresis. Results have also been obtained for the incorporation of radio isotopes (carbon-14 and sulphur-35) into individual protein components separated by starch-gel electrophoresis. Changes in protein composition during development of the endosperm have been shown to be quantitative rather than qualitative, while the differences in protein composition between the three wheat varieties investigated are present throughout development. Moreover, using starch-gel electrophoresis, it is possible to show a relationship between the protein components of similar genotypes in both wheat and barley. It is suggested that this may provide a sensitive analytical tool for cereal breeding work.

Separation of the protein components by starch-gel electrophoresis has shown that Osborne's procedure[6], based purely on solubility, does not give a true qualitative separation of wheat flour proteins. Since there is no qualitative distinction between proteins extracted by different solvents it is considered that in order to obtain a clear understanding of protein synthesis in wheat endosperm it is necessary to carry out biochemical studies on isolated morphological components. Ribosomes, amino-acid acceptor-RNA and the amino-acid activating enzymes have been prepared from immature endosperm, and synthesis of endosperm proteins *in vitro* may now be envisaged.

CONVERGENCE AND PROGRESSION IN *EUCALYPTUS* AND *SYMPHYOMYRTUS*

By STELLA G. M. CARR and PROF. D. J. CARR

Department of Botany, The Queen's University of Belfast

IN a previous communication[1] we showed that the eucalypts can be divided into two groups on the basis of perianth characters. The divisions thus proposed are supported by vegetative characters such as stellate hairs and by differences in characters of the inflorescence. It was suggested that the group of species in which the operculum is developed from a single perianth whorl and in which the sepals are absent or persist on the fruit as teeth constitutes a sub-genus, for which we coined the informal name '*Monocalyptus*'. We directed attention to the fact that Gauba and Pryor[2] had established that the seeds of the species of the Renantherae (the nomenclature adopted throughout is that of Blakely[3]), which constitute a large part of this sub-genus, have testas formed from both integuments. They also found that *E. jacksoni*, placed by us in *Monocalyptus*, has this type of seed-coat. Since then the same authors[4] have shown that the seeds of members of the series Eudesmieae (also in *Monocalyptus*) have double seed-coats and that the seeds of the remainder of the eucalypts studied by them have a testa formed from the outer integument only.

We have investigated the other species of *Monocalyptus*, namely, those of the series Miniatae as well as *E. pressiana*, *E. megacarpa* and *E. gamophylla*, and the group of species, *E. pachyloma*, *E. diversifolia*, *E. santalifolia*, *E. todtiana* and *E. patens*, which constitute the section Renantheroideae and find that all have seeds with double seed-coats. This character, then, is constant in *Monocalyptus*. The constancy of the characters of the seeds and the perianth can therefore now be adduced, together with the fact that, although many cases of hybridity have been recognized in the eucalypts[5], there is no authenticated record of a hybrid between those species with a seed-coat formed from both integuments and those without this character[6] as evidence for the view that the old genus *Eucalyptus* really consists of two separate but remarkably convergent genera.

We now propose to abandon the informal name *Monocalyptus*. Instead we have elsewhere[7] proposed to designate the mono-operculate species with a double seed-coat as *Eucalyptus* '*sensu stricto*', segregating them from the rest of the eucalypts, which we propose to call *Symphyomyrtus*. This nomenclature follows from the fact that the type species, *E. obliqua* L'Hérit., is mono-operculate and that *Symphyomyrtus* (*S. lehmannii* Schau. syn. *E. lehmannii* (Schau.) Benth.) is the only available synonym for any of the other species. The chief characters of these two genera, of which a full and valid description has already been provided[7], is as follows: *Eucalyptus* L'Hérit. emend Carr and Carr: sepals absent or, if present, alternating with the petals and consisting of four, rarely five, teeth, persistent on the fruit. Stamens forming a continuous ring, or grouped on staminophores opposite the petals. Inflorescence buds with an involucre rarely of more than six

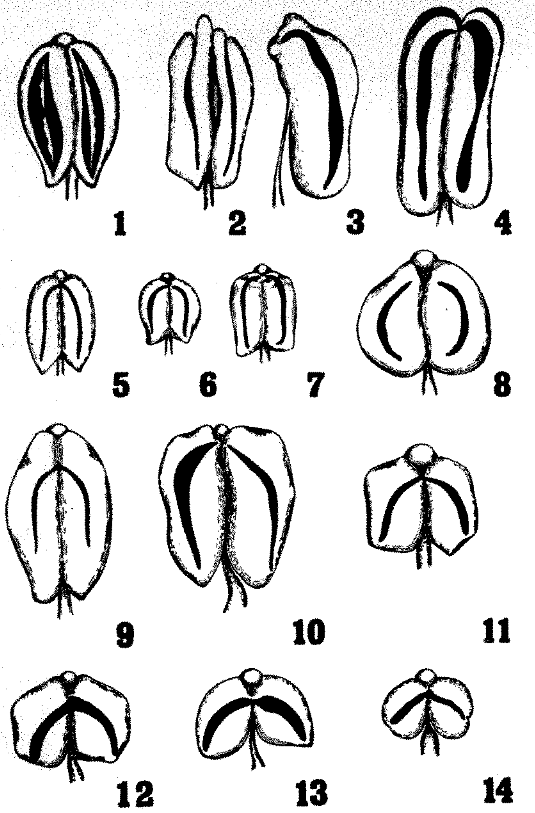

Fig. 1. Drawings of stamens of species of *Eucalyptus*

1, *E. erythrocorys*; 2 and 3, *E. phoenicea* (Miniatae) (3 is a side view); 4, *E. mitrata* ('Megacarpae'); 5, *E. curtisii*; 6, *E. gamophylla*; 7, *E. baileyana* (1, 5, 6 and 7, Eudesmieae); 8, *E. planchoniana*; 9, *E. sepulcralis* (8 and 9, Renantherae); 10, *E. pachyloma* (Renantheroideae); 11, *E. macrorrhyncha*; 12, *E. obliqua*; 13, *E. pauciflora*; 14, *E. coccifera* (11–14, Renantherae)

bracts. The testa of the seed is the product of two integuments. *Symphyomyrtus* Schau. emend Carr and Carr: sepals present, rarely completely free, usually partly or wholly united and caducous either before or at anthesis. Stamens forming a continuous ring. Inflorescence buds with an involucre of bracts always related in number to the number of flowers. Seeds with a testa formed from one integument.

According to this arrangement, the genus *Eucalyptus* would comprise the series Eudesmieae (12 species), with the exception of *E. lirata* but with the inclusion of *E. gamophylla*, the series Miniatae (2 species), *E. jacksoni*, *E. preissiana*, *E. megacarpa* and *E. mitrata* (see following), the section Renantheroideae (5 species) and the Renantherae (104 species) (except *E. guilfoylei*, *E. microcorys* and the series Myrtiformes). We shall use the name *Eucalyptus* only in this restricted sense. *Symphyomyrtus* would contain all the other eucalypts recognized by Blakely. The common name 'eucalypt' will be used for members of both genera. Since the relationships within the genus *Eucalyptus* are the more clearly defined, our attention has been directed principally to it rather than to *Symphyomyrtus*, in which relationships are more complex and of which many species are imperfectly known. The new arrangement cuts right across that based on anthers (shapes and modes of dehiscence) which has been in use since it was originated by Bentham[8]. It now seems abundantly clear that the classification based on anthers was of very limited usefulness, and, as Bentham realized, by its insistence on a single character, inevitably led to many anomalies (see also Blake[9]). The species of Eudesmieae, Renantheroideae and Renantherae can be arranged, for example, to show a continuous gradation of anther forms, ranging from those in which the anther cells are parallel and dehiscence is by parallel, longitudinal slits to those in which the anther cells are divergent and the slits are confluent across the face of the anther. Because this gradation has been overlooked in the past, certain species with intermediate anther shapes (for example, *E. stricta*, *E. alpina*, *E. baileyana*, *E. tenuipes*) have undergone several taxonomic removes[5]. Transitions are also found in the size of the sepal-teeth and the degree of fusion of involucral bracts and the association between these characters and the presence of stellate hairs and the grouping of the stamens on staminophores.

Recent work on the ovules and placentas has confirmed and extended this new view of the taxonomy of the eucalypts. The occurrence on the placentas of many members of Myrtaceae of congenitally sterile ovule-like structures is well known, but no special term has been applied to them. They have been referred to as 'sterile ovules', but this term is ambiguous. As we shall refer to these structures many times here and in the extended account which is in preparation[11] we propose the term 'ovulode' (ovulodium, pl. ovulodia). The numbers of rows of ovules and ovulodes and the disposition of these structures on the placenta, as well as certain other characters of the gynœcium, are of considerable taxonomic value.

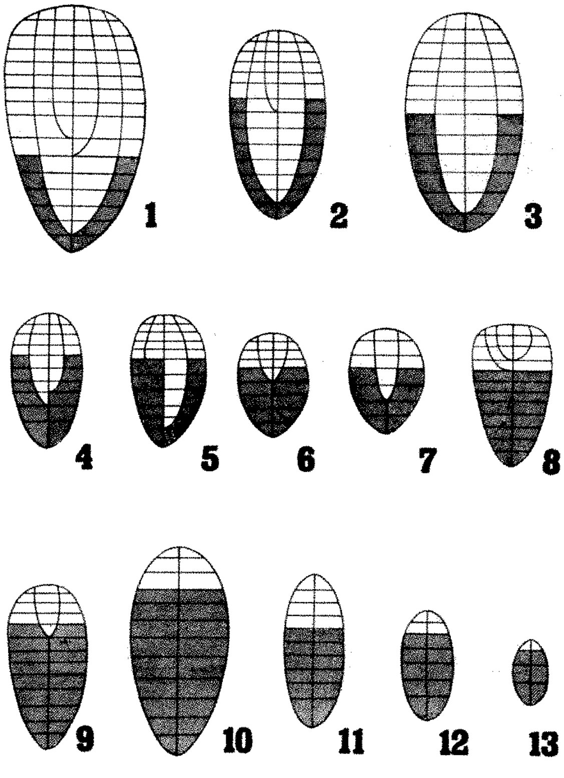

Fig. 2. Diagrams of the disposition of ovules and ovulodes on the placentas of species of *Eucalyptus*. Each 'cell' of each diagram represents an ovule (shaded) or an ovulode (unshaded)

1, *E. erythrocorys*; 2, *E. tetrodonta*; 3, *E. tetragona*; 4 and 5, *E. eudesmioides*; 6, *E. gamophylla*; 7, *E. odontocarpa* (1–7 Eudesmieae); 8 and 9, *E. patens* (Renantheroideae); 10, *E. preissiana* ('Megacarpae'); 11, *E. sepulcralis*; 12, *E. kybeanensis*; 13, *E. yangoura* (11–13, Renantherae)

This may best be shown by a consideration of the genus *Eucalyptus*. In *E. erythrocorys* (Eudesmieae) the ovules and ovulodes are arranged in approximately 20 transverse rows on each placenta and at its broadest part are in 6 longitudinal rows. The ovules occupy the margins of the lower part of the placenta and are in two rows separated by two rows of ovulodes (Fig. 2). Other members of the Eudesmieae exemplify a transition to a situation in which the lower part of the placenta is occupied exclusively by two longitudinal rows of ovules and the upper part by three longitudinal rows of ovulodes (Fig. 2). There is a corresponding reduction in the number of transverse rows as well. There is some correlation between the number of transverse rows and the length of the flower bud, but little between the number of longitudinal rows and the bud length. In the section Renantheroideae the ovules and ovulodes are, with one exception, in two longitudinal rows. In *E. patens* the ovules are in two rows, the ovulodes at the top of the placenta in three to five rows (Fig. 4, c.f. *E. gamophylla* and *E. odontocarpa*). In the Renantherae, also, the ovules and ovulodes are in two longitudinal rows (Fig. 5). This facilitates the recognition of their fruits and seeds. The scars of attachment of the ovules and ovulodes can be seen easily with a hand lens in fruits of all stages of maturity.

This should prove to be an invaluable field and herbarium character for the recognition of the members of this large group, since the two-rowed condition is not found in any other group of eucalypts. Grose and Zimmer[10] examined the shapes and other characters of the seeds and 'chaff' (ovulodes and infertile ovules) of the Victorian species and point out that the seeds and 'chaff' of renantherous species are generally D-shaped. This is in conformity with the fact that the ovules and ovulodes are in two rows and the seeds and 'chaff' have straight edges from mutual pressure along the mid-line of the placenta, while their outer surfaces are curved in conformity with the curve of the loculus they fill. These facts have enabled us to recognize *E. mitrata* as a member of *Eucalyptus*. Blakely places it with *E. preissiana* and *E. megacarpa*. Gardner (personal communication) also stresses its affinity with these species, already recognized as members of *Eucalyptus* in the strict sense. It has not proved possible to obtain sufficiently young flower buds of *E. mitrata* to ascertain whether it has only one perianth whorl. Nevertheless, the fact that its ovules and ovulodes are in two rows, taken together with the other resemblances to *E. preissiana* and *E. megacarpa*, and especially the fact that its seeds have a double seed-coat, warrants its inclusion in *Eucalyptus*.

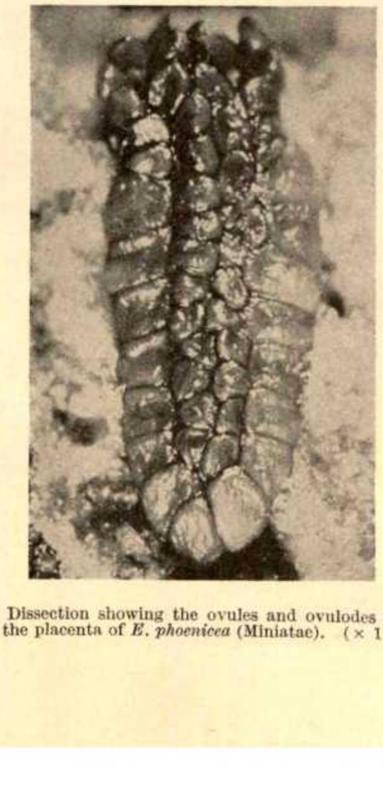

Fig. 3. Dissection showing the ovules and ovulodes *in situ* on the placenta of *E. phoenicea* (Miniatae). (× 17)

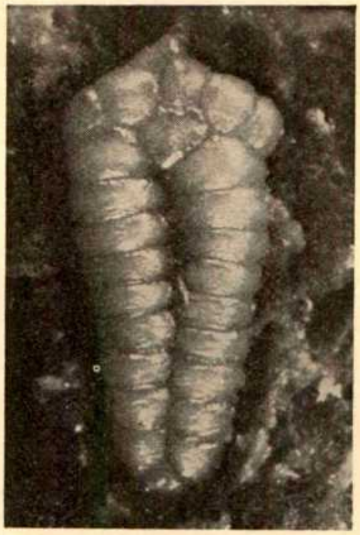

Fig. 4. Dissection of *E. patens* (Renantheroideae). (× 18)

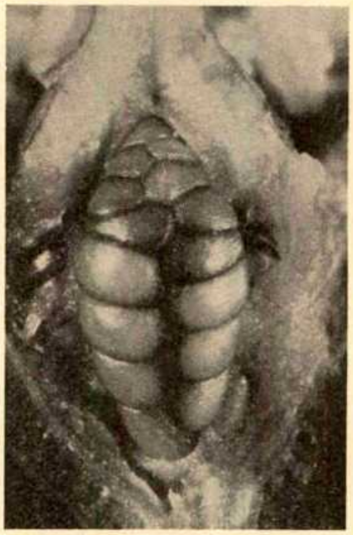

Fig. 5. Dissection of *E. marginata* (Renantherae). (× 19·5)

There is a progressive reduction in the number of longitudinal rows of ovules from six to two and a corresponding reduction in the number of transverse rows in the order Eudesmieae–Renantheroideae–Renantherae. Although each species has its characteristic pattern of arrangement of ovules and ovulodes, there is sufficient variation within certain species (for example, *E. tetrodonta*, *E. eudesmioides* and *E. patens*) to illustrate steps in this reduction at an intraspecific level (Fig. 2). The ratio of the number of ovules to ovulodes increases in the same order, from less than one in the Eudesmieae to more than one in the other sections. The shape of the anther changes in the same order from the so-called 'macrantherous' anthers of some Eudesmieae and of the Miniatae, and those of the 'Megacarpae' (*E. preissiana* and its allies) in which the large anthers have parallel cells but the dehiscence slits are convergent or confluent, to the intermediate condition of the anthers of Renantheroideae and, finally, to the fully 'renantherous' condition in the Renantherae (Fig. 1). Variations and trends in the patterns of arrangement of the ovules and ovulodes, similar to those in *Eucalyptus*, are found also in *Symphyomyrtus*, but the number of longitudinal rows in the latter is never less than four. The similarities between the two genera are as striking in this respect as in many others and testify to their unusual degree of convergence. We shall elsewhere[11] deal more fully with *Symphyomyrtus*.

An examination of ovule and ovulode development[11] has shown that in species in which there are only two longitudinal rows on the placenta, the first primordia to be initiated are those at the top, and the last those at the bottom of the placenta. In species in which there are more than two rows the first primordia are those at the centre of the uppermost transverse row. These are followed by primordia occupying the outer positions on the same transverse row and the central positions of the transverse row below. The last to be initiated are those of the lowest and outermost rows on the placenta. Reference to Fig. 2 shows that the first-formed primordia always develop as ovulodes and that the last-formed are always ovules. There is thus a close parallel with the development of the first-formed stamen primordia to staminodia (lacking anthers) and of the later stamen primordia to functional stamens[11] which is a feature of many eucalypts. Staminodia are found in a few of the Eudesmieae but are rare, if they occur at all, in the other species of *Eucalyptus*. Thus in the order Eudesmieae–Renantheroideae–Renantherae the sterility of the first-formed sporangia is increasingly suppressed.

Among the 12 species of Eudesmieae there is a much greater diversity in the characters of the perianth, anthers and arrangement of the ovules and ovulodes than in the other sections of *Eucalyptus*. *E. curtisii* and *E. tenuipes*, two somewhat anomalous members of Eudesmieae, for example, have many similarities and have long been recognized as being closely related, but they differ considerably in the arrangement of their ovules and ovulodes. In *E. curtisii* the very small ovules and ovulodes are arranged in six longitudinal rows, the ovules occupying the whole of the lower part of the placenta, the ovulodes, unusual in being scarcely distinguishable from the ovules, the upper half. In *E. tenuipes* the ovules again occupy the whole of the lower half of the placenta, but they are in four longitudinal rows and the ovulodes are in only two rows. The Miniatae, at present constituted by the two species *E. miniata* and *E. phoenicea*, may be considered as closely allied to the Eudesmieae. The number of rows of ovules and ovulodes and the pattern of their arrangement (Fig. 3) is remarkably similar in both species and resembles that in *E. erythrocorys*. It has been suggested by Blake[9] that, on the basis of other resemblances, *E. similis* might be placed with the Miniatae. It is therefore of considerable interest that the pattern of ovule and ovulode arrangement in *E. similis* is very like that of the Miniatae.

When the species of *Eucalyptus* are arranged in the order Eudesmieae–Renantheroideae–Renantherae progressions in many characters, both reproductive and vegetative, suggest themselves. For example, *E. erythrocorys*, a typical member of the Eudesmieae, has sepals, staminophores, large numbers of ovulodes and a small ratio of ovules to ovulodes, large flowers in groups of three with two free bracts. It attains a height of 9 m, has stellate hairs and a lignotuber. At the other end of the scale, *E. regnans*, a typical member of Renantherae, has no sepals or staminophores, few ovulodes, and a ratio of ovules to ovulodes greater than one, small flowers in clusters of seven to fifteen, with a mean number of eleven, with six fused bracts. It attains a height of 90 m and has neither stellate hairs nor a lignotuber. Nevertheless, the characters of these two species represent the extremes of morphological series in each of which every step can be exemplified by species of *Eucalyptus*. In all these series the progression is from the Eudesmieae to the Renantheroideae and the Renantherae. We venture to suggest that these progressions in morphological characters, discussed here and elsewhere[11], indicate that the Renantherae and Renantheroideae have evolved from a eudesmioid complex, the few present-day representatives of which betray the degree of variation one might expect in the remnants of an older group from which have sprung the new but comparatively uniform groups of species which constitute the rest of the genus *Eucalyptus*. We have suggested[7] that in the evolution of *Eucalyptus* selection has operated to increase the overall growth-rate, the life-span having been less affected. The progressive reduction in the size of the sepals which is exemplified by some of the Eudesmieae, leading finally to their complete absence in most members of *Eucalyptus*, has been attributed[7] to a shift in timing of sepal and petal growth and in the allometry of sepal and petal growth as by-products of the general trend in the genus towards higher growth rates.

The Miniatae can be considered as an offshoot linked through *E. similis* with the Eudesmieae proper, and comparable in degree of evolution of inflorescence and perianth characters, although not those of stamens or ovules, with the Renantheroideae and Renantherae. *E. curtisii* and *E. tenuipes* are perhaps the remnants of an eastern eudesmioid group, a suggestion which is strengthened by their geographical isolation (they occur close together in southern Queensland) from the rest of the Eudesmieae.

We thank Mrs. W. A. Ross, Hamel, Western Australia, for information and material; Mr. A. K. Cameron, Melbourne, for the loan of his herbarium; and Mr. E. J. Sonenberg, University of Melbourne, for technical assistance.

GEOPHYSICS

Earth's Central Density

In a paper to be published elsewhere, I have derived the formula:

$$\eta = \frac{\mathrm{d}k}{\mathrm{d}p} - g^{-1}\frac{\mathrm{d}\varphi}{\mathrm{d}z} \qquad (1)$$

where η is a measure of departure from chemical homogeneity at depth z in the Earth (here treated as spherically symmetrical); k, p and g denote the adiabatic incompressibility, pressure and intensity of gravitational attraction, and φ is a function of the P and S seismic velocities. The index η is equal to unity where the Earth is chemically homogeneous, in accordance with a simpler formula[1] developed in 1949; η exceeds unity where the chemical composition is varying with the depth z. An important property of η is that it is equal to the ratio of the actual value of $\mathrm{d}\rho/\mathrm{d}z$ (where ρ denotes density) to the value $\mathrm{d}\rho/\mathrm{d}z$ would take if the composition were unvarying.

Since η depends only on $\mathrm{d}k/\mathrm{d}p$, g and $\mathrm{d}\varphi/\mathrm{d}z$, it is possible to set bounds to η throughout most of the Earth, and so set bounds to the possible density gradients. Physical evidence indicates that $\mathrm{d}k/\mathrm{d}p$ is of the order of 3–5 units in the Earth's deep interior, g is determined in the Earth within uncertainties which reach a maximum of 30 per cent and are mostly much less, while $\mathrm{d}\varphi/\mathrm{d}z$ is directly yielded from the seismic velocity distributions. More complete numerical details on the derivation and use of equation (1) are being set down elsewhere.

Equation (1) acquires some immediate special interest through Bolt's revised P velocity distribution[2] in the Earth's core. The P velocity distribution previously obtained by Jeffreys[3] gave $\mathrm{d}\varphi/\mathrm{d}z$ negative and appreciable in magnitude in the region F. By equation (1), the Jeffreys distribution is found to entail a value of η of order 30 units in F, and thence, in agreement with my Earth model B calculations[4], a large density increase (of about 3 g/cm^3) in this region, resulting in an estimated density of order 18 g/cm^3 at the Earth's centre.

One of the features in Bolt's new distribution is the reduction of $|\mathrm{d}\varphi/\mathrm{d}z|$ to zero in F. By equation (1), this reduces η from about 30 units to the value of $\mathrm{d}k/\mathrm{d}p$, expected to be 4–5 units in this part of the Earth. Thus the value of $\mathrm{d}\rho/\mathrm{d}z$ in F is reduced to one-sixth or less of the value which corresponds to the Jeffreys distribution.

Much detailed analysis, to be presented in a later paper, is required to work out fine details of the density revision in the core required by Bolt's new seismic velocities, since g itself depends on the density distribution. There are also other aspects of the new velocity distribution to be taken into account. But equation (1) has the value of providing a useful first approximation which shows at a glance that the new velocity distribution can permit a substantially reduced estimate of the Earth's central density. The indicated reduction is of the order of 2 g/cm^3 at least.

This is a result of considerable significance to the physics of the Earth's core. Many investigators have found difficulty in accepting a central density as high as 18 g/cm^3. So long as the Jeffreys velocity distribution is used, equation (1) shows immediately that it is difficult to reduce this figure. But with Bolt's distribution, which, incidentally, is compatible with the travel-time data used by Jeffreys, and in fact includes the latter, a central density of order 16 g/cm^3 (possibly a little less) becomes not only possible but also the preferred figure. Thus the revision is in the direction of reconciling previously discordant views on the properties of the Earth's core.

Cape Town Anomaly and Auroral Emission

It has been recognized since the time of the *Argus* experiments[1,2] that the anomalously low value of the Earth's total magnetic field in the South Atlantic region must have a profound effect on the particles trapped in the radiation belts. The most convincing illustrations of this are the counting-rates of charged particles observed at relatively low altitudes with the Russian cosmic ships[3,4] and recent American satellites in the *Discoverer* series[5]. The maps prepared by both groups show two regions of high radiation intensity in the area of the South Atlantic Ocean, at heights of 250–500 km, where the counting-rates exceed those at corresponding geomagnetic latitudes elsewhere by factors of the order of 1,000 or more. One of these regions, coinciding well with the centre of the magnetic anomaly off the coast of Brazil, is attributed to the inner radiation belt. The other, referred to as the 'south radiation anomaly', lying between Cape Town and Antarctica, is thought to be due to the outer belt. These assignments are supported by the observation that the *Argus* belts of particles lay in the region between the two natural radiation belts[1], corresponding to the positions of the detonation sites between the two recently discovered anomalous radiation zones.

It is the purpose of this communication to point out that the particle flux into the south radiation anomaly is probably large enough to produce observable auroral effects.

Fig. 1 shows the south radiation anomaly as observed by the Russian second cosmic ship[3] and the traces on the Earth's surface of the mirror points of particles entering the zone, estimated with the aid of the longitudinal integral invariant curves published by Vestine and Sibley[6]. Both the northern and southern traces are shown.

O'Brien *et al.*[7,8] have recently reported data telemetered from the satellite *Injun I*, giving electron energies, fluxes and pitch angles at heights of the order of 1,000 km in the vicinity of Iowa City, which is indicated by the point C in Fig. 1. It is evident that these data may be used as a reasonable sample of the

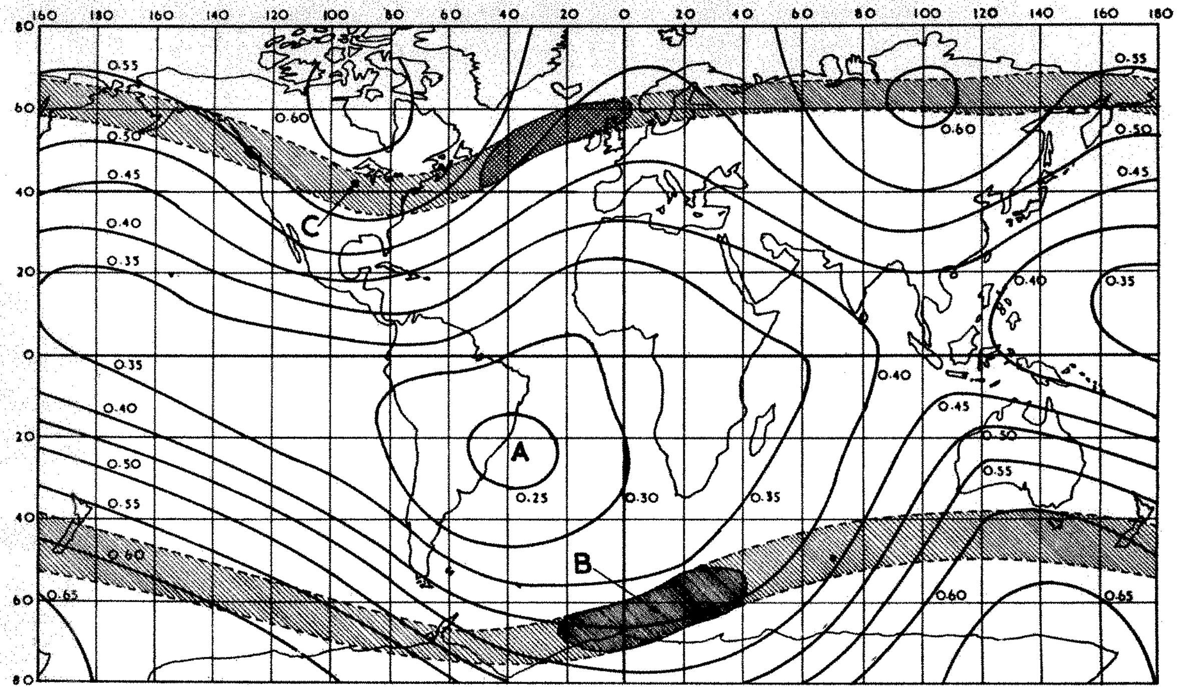

Fig. 1. The geomagnetic anomaly (*A*), the south radiation anomaly (*B*) and traces of the mirror points of electrons falling into the latter. *C* indicates the position of Iowa City

properties of electrons entering the south radiation anomaly. Taking 0·36 gauss as a representative value of the magnetic field in the region sampled[7], it is possible to compute the mirror heights of the trapped particles at other points in their orbits. Fig. 2 was prepared in this way, assuming an inverse cube field and taking the values of the magnetic field at the Earth's surface from Fig. 1. It shows very clearly the pronounced effect of the magnetic anomaly in lowering the mirror points and demonstrates that all the electrons seen by *Injun I* at 1,000 km over Iowa will penetrate to heights below 150 km in the south radiation anomaly, that is, below the F-2 region of the ionosphere. Related graphs have been prepared for other latitudes by other workers[2,9,10] and lead to similar conclusions.

We therefore base our estimates on an assumed energy flux of the order of that found by *Injun I* at 1,000 km over Iowa, namely 100 ergs (cm^2 sec)$^{-1}$, about 90 per cent of this being carried by electrons in the energy range 1–40 keV[7].

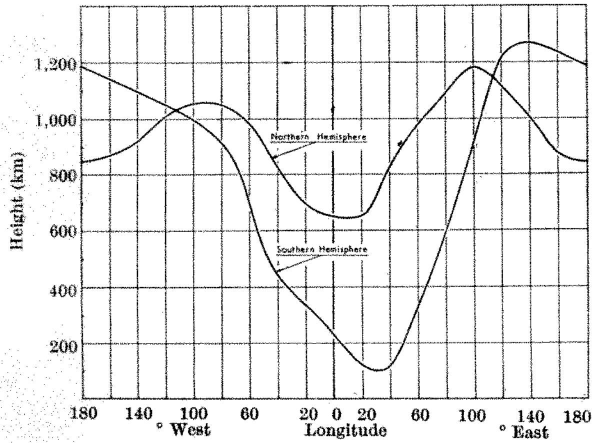

Fig. 2. Mirror point heights for electrons mirroring at 1,000 km over Iowa City

McIlwain[11] has reported measurements of the incident energy flux and electron energy spectrum responsible for two visible auroral displays, obtained by firing instrumented rockets into the upper atmosphere at Fort Churchill, Canada. For "a faint, quiescent auroral glow" he found the electrons to have energies most probably in the range 3–30 keV, with an incident energy flux of 20 ergs (cm^2 sec)$^{-1}$. In a "bright auroral arc" he found almost monoenergetic electrons at about 6 keV to be responsible, the maximum incident flux being then 2,000 ergs (cm^2 sec)$^{-1}$. The intensities of the two auroræ, measured at the ground, were about 0·08 and 0·4 erg (cm^2 sec)$^{-1}$ respectively.

The greater part of the flux which we have estimated to be incident on the south radiation anomaly consists of electrons in just this energy range, and its numerical value lies between those observed in the two auroræ. We may thus expect to find a more or less permanent aurora, possibly even of visible intensity, in this region. The intensity as measured at the ground should be at least 0·1 erg (cm^2 sec)$^{-1}$, or 30 kilorayleighs. Since the normal airglow intensity at these latitudes is a few hundred rayleighs[12] this should be readily detectable. Both McIlwain's observed flux and our assumed one refer to the incident particles, so that the foregoing estimate is presumably valid regardless of what actual fraction of the incident energy is absorbed or converted to light, since the conditions are very similar.

One may wonder why, if there is a permanent glow, faint but nevertheless of visible intensity, it has not been reported by the whalers and expeditions passing through the region. The explanation may well lie in the absence of a background for comparison, so that although the glow is sufficiently intense to be seen, it is so uniform over the visible sky that its presence goes unnoticed. Sandford[13] has discussed this phenomenon in respect of the polar glow, which, even though it may reach "such a brightness that observation of the Milky Way is difficult", may nevertheless be "so uniform over the whole sky that it is not possible, unless the sky appears coloured, for an observer to say for certain that there is an aurora".

By kind permission of the Department of Transport of the South African Government, facilities have been made available for the observation of auroral and other geophysical phenomena from the research ship *R.S.A.* when she is operating in the regions of interest.

We thank Prof. F. D. Seward for making his maps of radiation intensities observed with *Discoverer XXXI* available to us before publication.

OCEANOGRAPHY

Preliminary Heat-Flow Profile across the Atlantic

DURING the 1962 *Zephyrus* expedition of the Scripps Institution of Oceanography, University of California, fourteen heat-flow measurements were made from Martinique to the Canary Islands. The measurements are on a line except on the crest of the Mid-Atlantic Ridge, where an area was sampled. The instrumentation has been discussed previously[1,2], and our preliminary values are presented in Table 1 and in Fig. 1 with bathymetry.

The results indicate a variation by a factor of about twenty, from 0·3 to $6 \cdot 5 \times 10^{-6}$ cal/cm² sec. High values occur in a belt 200 km wide on the crest of the Mid-Atlantic Ridge and low values are found on its flanks, forming a heat-flow pattern similar to that of the East Pacific Rise[3].

Table 1. HEAT-FLOW VALUES AND LOCATIONS

Station No.	Latitude (N.)	Longitude (W.)	Depth (m)	Thermal conductivity 10^{-3} cal/° C cm sec	Heat-flow 10^{-6} cal/cm² sec

ASTRONOMY

Dimensional Correlation of Lunar Maria and Terrestrial Ocean Basins

IN a previous paper[1] I have shown that the correlation of diameter versus depth for lunar craters of different apparent ages can be understood in terms of the former presence of a lunar hydrosphere lasting some milliards of years, affecting the relative dimensions at crater formation. Furthermore, this correlation of dimensions included the lunar maria, and was extended later[2] to include the terrestrial ocean basins (corrected for isostasy from the mensuration of present basins). The purpose of this communication is to correct a difficulty in the correlation curves for craters formed explosively in water.

The correlations obtained between the diameter D and depth d for terrestrial explosion and meteoritic craters on land, and for lunar craters of Classes *IH* and *IS* (the youngest), are represented by the lowest curves (continuous) in Fig. 1, given by:

$$D = a_1 d[1 + (d/a_2)] \qquad (1)$$

with a_1 and a_2 constants. To the eye, it appears that an extension of the continuous curves for craters on land might intersect the points for the anisostatic ocean basins. This conclusion is incorrect, as shown by the analytic extrapolations (dot-dashed) from equation (1). However, a different difficulty appears, since both curves in question eventually will intersect the extrapolations (shown dot-dashed) of the curves for craters formed in water. The latter curves were presumed to correspond to craters from surface explosions in water of depth δ, where the parameter $\mu = \delta/d$ has the constant value of unity. It is obvious that two curves of D versus d for the same rock type but differing values of μ cannot intersect, since the depth of water δ must be single-valued. A sufficient condition that two curves of form (1) do not intersect is that a_1 be different but a_2 be the same. In Fig. 1, revised curves of D versus d for $\mu = 1$ are shown (continuous) for hard and soft rock, constructed by taking a_2 equal to the value for craters on land, so that no intersection of corresponding curves for $\mu = 1$ and $\mu = 0$ is possible. The values of a_1 for $\mu = 1$ were fixed from the dimensions of two craters in hard and soft rock, Glasstone (H) and Glasstone (S), respectively, corresponding to nuclear explosions in water[3]; the values are insensitive to μ so long as it lies in the range 1/2–2 (and not 1/12–2, given previously)[1,2].

One notes from Fig. 1 that the points for the larger maria show a general progression away from the revised curve for hard rock with $\mu = 1$, as d increases, in the direction of the corresponding curves for craters on land. Further, the points for the anisostatic ocean basins no longer lie on the locus for $\mu = 1$, as they did in the former case. These points tend to fall on a line segment lying closer to the curves for $\mu = 0$ than the one for which $\mu = 1$, and show a steady progression with increasing d in the direction of the former loci.

It is asserted that the progression of the points for the lunar maria and anisostatic ocean basins from the curve for $\mu = 1$ toward the curves for $\mu = 0$ represents an effect of lessening water depth relative to crater depth, corresponding to the circumstances of the meteoritic explosion. Mean depths of water determined[1,2] previously have been used to fix μ for the maria and ocean basins; some values appear in Fig. 1. On the basis of the limits $1/2 < \mu < 2$ from Glasstone's data, the points for Humboldtianum and the Arctic should lie on and near, respectively, the curve for $\mu = 1$, as is true. For the remaining maria and ocean basins, the values of μ require that the points should be displaced away from the curve for $\mu = 1$ toward the curves for $\mu = 0$, in a progression varying monotonically with μ. The observed progression is monotone, in general, up to the point for the South Pacific, which lies close to the loci for $\mu = 0$ because of the small value (1/13) of μ.

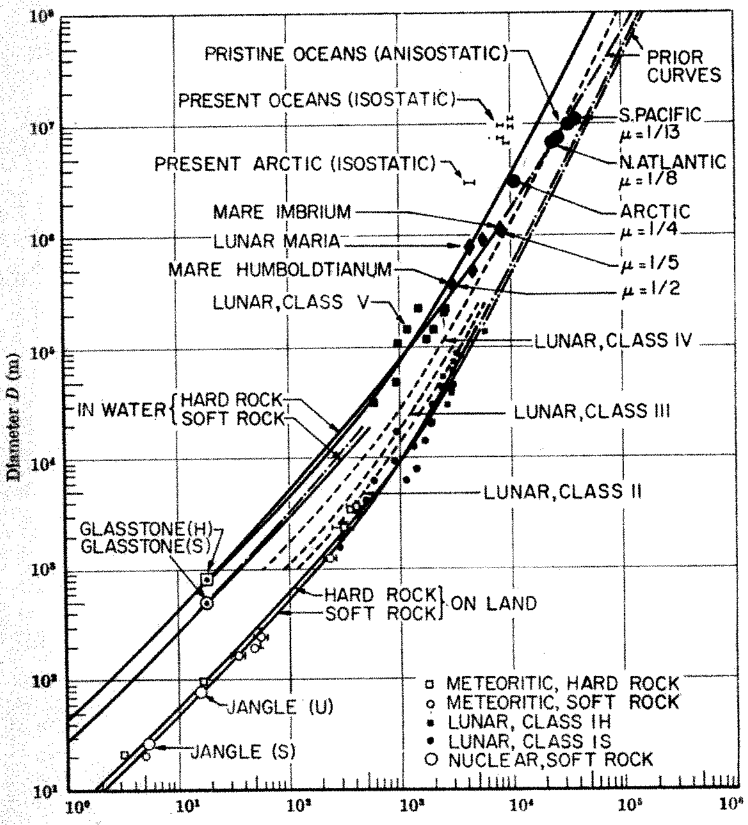

Fig. 1. Correlation curves of diameter versus depth from the present work compared with previous work, for the present and pristine oceans, the lunar maria, and various classes of craters

With this revision of the curves, the representative points for the lunar maria and terrestrial ocean basins show a progression as a function of μ, precisely analogous to that with ordinal number of the class for the points corresponding to the older lunar craters of Classes II, III, and IV, as indicated by the correlation curves shown dashed in Fig. 1.

PHYSICS

Possible Hydrodynamical Character of Moving and Stationary Striations

THE striated column of the glow discharge has long been one of the most tantalizing phenomena in Nature. Although many theories have been advanced to account for this effect, none has yet met acceptance except perhaps in limited and specialized situations. The extensive and well-known literature is too voluminous for discussion here. Only a few typical references will be cited[1-4]. It is the purpose of this communication to direct attention to a mechanism which can give a unifying framework for the basic phenomena of these striations. The salient features of this new hypothesis will be outlined here; but the details will be reserved for a future report, which is now in process of preparation.

An ordinary fluid is capable of two (irrotational) modes of action: flow motion and wave propagation. When the fluid is compressible, the wave propagation proceeds as a series of compressions and rarefactions (sound waves) if the amplitude is small; but the compressions steepen into shock waves because of the non-linearities in the laws of compressible hydrodynamics when the amplitude is even moderately large. Weak shock waves travel with nearly the same speed as sound (Mach number of order unity); but strong shocks move with supersonic speed. When flow motion and wave motion are both present, the wave moves with the combined speed of both motions. It may seem from laboratory co-ordinates to advance at high speed, to stand still or even to drift backwards depending on the relative directions and magnitudes of the flow velocity and sound velocity. When the wave in question is a shock wave, a moving or stationary discontinuity rides on the flow. In water waves (where the free surface simulates compressibility) these effects are well known and are called 'bores' or 'hydraulic jumps'.

Plasmas display hydrodynamical behaviour and can generate both acoustical waves[5] and shock waves[6]. They are the result of disturbances in which the electron pressure and the ionic mass combine to determine a wave speed $c = (\gamma k T_e/M_i)^{1/2}$ which we will call the plasma-acoustic speed. Here γ is the specific heat ratio of the ideal electron gas, that is, 5/3.

The hypothesis presented here is that striations in the majority of cases are plasma-acoustic shock waves of moderate strength moving relative to the electron current of the column. Striations are known to move both directions in the column at the same time. Those moving from cathode to anode are always fast. Those moving from anode to cathode are slow, and may stop or even drift backward.

For very weak shock waves bordering on the acoustic, the speeds are linearly additive and the forward and backward speeds with respect to the laboratory system are:

$$U_{\pm} = c \pm U_d$$

where U_d is the drift velocity of the electron current. For strong shock waves great complications arise which require the solution of the entire problem of the structure of a single striation, since flow speeds must differ on the two sides of the shock, yet the pattern must repeat from striation to striation. Nevertheless, the condition that shock speed is equal to incoming flow speed can be fulfilled through the Hugoniot relation.

It is probable that the wave-length of the striations is determined by organpipe theory, as has been suggested by Coulter *et al.*[7], and the compressive region in each wave-length should then steepen into a shock across which there will be a potential step. This step has in fact been observed by Boyd[8] in the striations, and elsewhere by Hales and Josephson[9] as a normal concomitant of plasma shock fronts. A striation is thus a unit diffusion cell bounded by two shocks and the wall. Though the electron temperature T_e in a striated column can be described by an average value it is the extra excitation by fast electrons which have moved through this step with a consequent small rise in T_e in the head of a single striation which both produces the extra luminosity which renders the slow striations visible and furnishes the ionization needed to maintain ion balance against diffusion losses despite the low average energy of the bulk of the electrons. The number of electrons accelerated depends on the rate at which the striation advances in the laboratory frame. The energy balance condition in each striation cell is probably that the admixture of these fast and slow electrons equilibrates to a temperature at which the diffusion processes can dispose of the extra electrons produced by the fast component. Observations show that whenever a fast striation collides with a slow striation, luminosity is suppressed, and both striations momentarily stall. This would be because the potential steps, being in opposite sense, cancel each other and require some time to be restored.

Donahue and Dieke have given two points for which both the positive and negative striation velocities have been measured. They find in a 15-mm diameter tube at 3·82 m.amp and 2·1 mm mercury in argon 170 m/sec and 2,300 m/sec respectively; at 20 m.amp. and 12 mm mercury they find 50 m/sec and 1,500 m/sec. From these data we conclude that flow-speed and wave-speed are very closely adjusted to one another. It is only possible to set bounds on such quantities as the electron temperature until the complete theory is furnished. The range in which shock theory says the solution must lie gives a T_e between bounds of $1{\cdot}3 \times 10^3$ and $2{\cdot}1 \times 10^4$ °K for the first case, and between 5×10^2 and 8×10^3 °K in the second. The higher values are the more reasonable ones to expect and agree with the observations of Boyd.

The foregoing hypothesis is directed to the propagation mechanism in long columns only. The excitation of striations probably depends on instabilities at the cathode, recognized by Emeleus[10], while a diffusion theory, such as that of Wojaczek[11], will be needed to describe the structure of a given striation. Instabilities at the anode may only be reflexions of fast negative striations. Whether they have an independent existence should be studied further.

Electron Drift Velocity in Liquid Argon and Argon–Nitrogen Mixtures

THE very large negative ion mobility observed by Malkin and Schultz[1] and by Williams[2] in liquid argon (about 10 cm²/V.sec) has been interpreted as indicating the existence of free electrons in this liquid. Estimates of the elastic collision cross-section by these authors on a basis of classical kinetic theory appeared to indicate that the liquid could not be considered as a compressed gas, but a comparative study of electron drift velocity data for mixtures of gaseous argon and small concentrations of molecular impurities showed that these earlier interpretations may be in error[3].

It was clear that further investigation was necessary, and this note presents some preliminary results obtained for the drift velocity of electrons in liquid argon and in liquid argon with nitrogen in solution. The experimental method was essentially the same as that of previous investigators[1,2]. Ions were produced close to the cathode surface of a parallel electrode gap by α-particles emitted from a deposit of plutonium-239. By using electrode spacings large in comparison with the length of the α-particle track any range effects could be neglected. The time-constant of the input circuit to the amplifier was made to be very long in comparison with the transit time of the electrons, and under these conditions the integrated

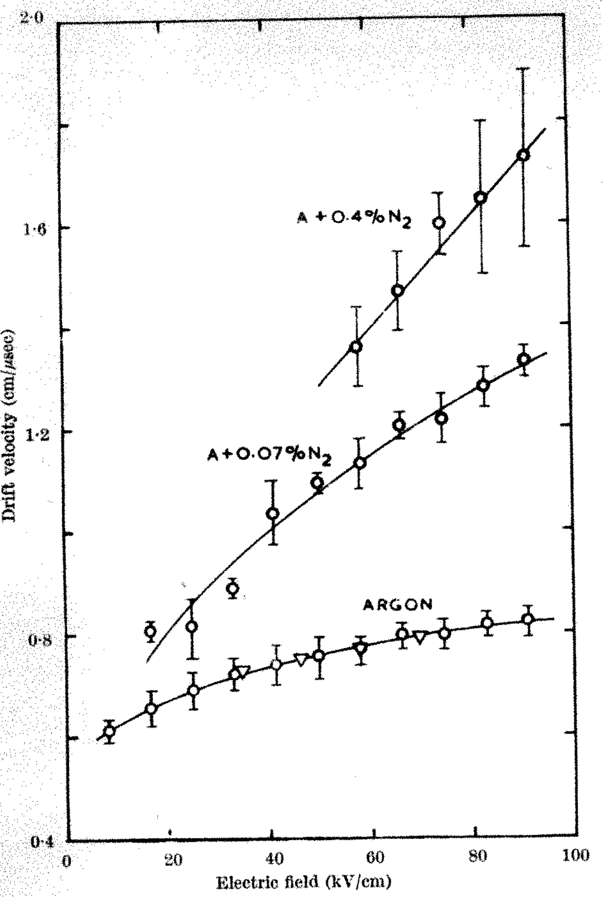

Fig. 1. Electron drift velocity in liquid argon and argon–nitrogen mixtures. Electrode spacing, ○, 1·2 mm; ▽, 1·72 mm

current pulse produced by the electrons in motion was observed using wide-band amplifiers and a high-speed oscilloscope. Individual traces were photographed and enlarged before analysis.

The argon used was of commercial grade, supplied by British Oxygen Gases and stated to be 99·995 per cent argon with nitrogen the principal impurity. When it was desired to mix nitrogen with the argon a known quantity of this impurity gas was admitted to the system first and argon was then condensed until a fixed volume of liquid was in the system. The percentage impurity was computed by assuming that all the nitrogen went into solution.

Fig. 1 shows the electron drift velocity as measured in the commercial grade argon and in argon–nitrogen mixtures for field strengths up to 100 kV/cm. It is seen that the addition of nitrogen increased the drift velocity considerably. With the larger nitrogen concentrations increased recombination in the α-particle track reduced the observed pulse height and measurements at low fields became more difficult. The drift velocity was found to be independent of electrode spacing within the experimental error.

The sensitivity of the electron mobility to small quantities of nitrogen in the argon suggests that the appreciable difference in drift velocity observed by previous investigators was probably due to variations in purity of the argon samples. The mobility-field relationship may be expressed in the form $\mu = AE^{-n}$, where μ is the mobility, E field and A a constant, and using this equation Williams's data yield a value of $n \approx 1$, while Malkin–Schultz found that $n = 0{\cdot}5$. For the three experimental curves given here, n is found to vary from 1·06 for the commercial argon to about 0·6 for the mixture with 0·4 per cent nitrogen.

There is also a very marked similarity in the behaviour of electrons in liquid and gaseous argon, as already suggested by me[3]. The momentum transfer cross-section of argon exhibits the Ramsauer minimum at about 1 eV, and because of this any reduction in mean electron energy will result in a decrease of the cross-section. While there are no inelastic collisions in argon below the first excitation potential, addition of a small quantity of nitrogen will introduce inelastic scattering at energies as low as 1 eV through the excitation of vibrational and rotational modes. The influence of the impurity, therefore, is to reduce the mean energy of the electrons, and as a consequence, to reduce the mean momentum transfer cross-section also. From kinetic theory the drift velocity at a given value of the ratio of field to density is inversely proportional to the momentum transfer cross-section and to the square root of the mean energy, and since both are reduced by the impurity the drift velocity increases. This effect has been fully studied for gaseous argon both experimentally[4] and theoretically[5].

In the liquid state the proximity of neighbouring atoms might be expected to modify the momentum transfer cross-section considerably, in which case the influence of impurities could be very different, but the results presented herein indicate that argon in the liquid and in the gaseous state behave in a similar way. These results suggest that in the liquid state the momentum transfer cross-section exhibits a Ramsauer type minimum as in the gaseous phase. However, the Ramsauer minimum arises from the form of the scattering potential assumed for the heavier of the rare gases, and the 'polarization correction' to the Hartree field which was introduced by Holtsmark in order to give good agreement between theory and experiment extends to well over 4 Å from the atom. In liquid argon the nearest neighbour to any atom can approach within 3·05 Å, while the mean separation between two atoms is 3·86 Å[6], and thus there would be considerable overlap and distortion of the scattering field. In view of this it is rather surprising that the drift velocity data presented here suggest that there is very little interaction between neighbouring atoms.

The results given for commercial grade argon do not by any means represent those for pure argon, and further experiments will be carried out using purified argon. The effect of other gases dissolved in argon will also be examined, and information gained on the electron trapping properties of the impurity molecules. Full accounts of this work will be published elsewhere.

This work was supported by a special research grant from the Department of Scientific and Industrial Research. I thank Prof. M. W. Humphrey Davies for facilities provided and Dr. T. J. Lewis for advice.

Polygonization in Silver Chloride

Jones and Mitchell[1] showed that etch pits were produced on surfaces of silver chloride crystals close to {100} by a 3 N solution of sodium thiosulphate, and demonstrated further that in many crystals (depending on the "precise crystallographic orientation of the surface and upon particular properties of individual crystals") there was a one-to-one correspondence between the etch pits and dislocation lines emerging at the surface. This technique has been used here to examine the dislocation arrangement in bent single crystals of silver chloride grown from the melt.

In the specimens used the surface normal to the axis of bending was close to {100}, deformation was by single slip and the dislocations introduced into the crystal by bending clearly lay on slip planes. Silver chloride deforms by pencil glide[2] and hence a surface showing straight slip traces presumably makes a small angle with the slip direction, and slip dislocations the lines of which are normal to it must be of predominantly edge character. Single crystal bars (about 1 × 3 × 40 mm) were polished in a solution of four parts of 3 N sodium thiosulphate and one part of ammonium hydroxide and then annealed *in vacuo* and allowed to cool slowly in the furnace, so that they appeared completely dark when viewed between crossed nicols. This indicated the absence of any long-range internal stresses. Etching in a solution of 3 N sodium thiosulphate for 1 or 2 sec at this stage showed that most of the 'grown-in' dislocations were, after annealing, arranged in low-angle boundaries. The crystals were then repolished, bent (plastically) at room temperature to a radius of 5 cm by means of a former and immediately etched.

This etching revealed the grown-in dislocations and also those introduced into the crystal by bending, and by comparison with the etch-pit pattern on the annealed crystal showed that the dislocations in the sub-boundaries play practically no part in the plastic deformation of the crystal (except possibly in the very narrow regions close to the surface where poor viewing conditions prevented observations being made). In the specimens used the dislocations produced by bending were arranged on slip planes as in Fig. 1, where the slip plane traces are parallel to the arrow. It can be seen that some of the dislocations have, without heat treatment, arranged themselves into small segments of low-angle boundaries approximately normal to the glide planes, a process termed 'glide polygonization'[3] or 'mechanical polygonization'[4].

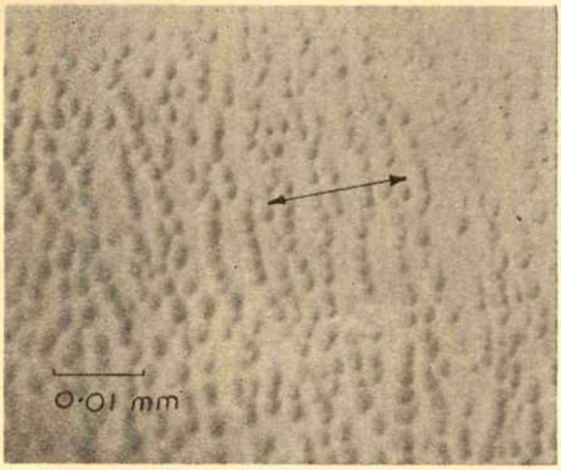

Fig. 1

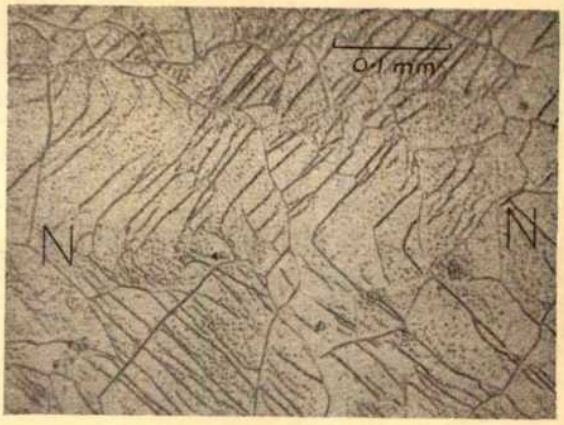

Fig. 2

The crystals were then repolished and annealed *in vacuo* and allowed to cool slowly in the furnace so that they appeared dark between crossed nicols. As a result of heating, the dislocations climbed into continuous low-angle boundaries normal to the slip planes (that is, thermal polygonization took place), to give Fig. 2, where *NN* is the neutral plane of bending. The crystal shown had deformed on different glide planes on opposite sides of the neutral plane and the dislocation climb on annealing produced the chevron pattern seen.

ENGINEERING

Electron and Ion Density Hysteresis Effects in a Low-Pressure Mercury-Vapour Plasma carrying a Current of Varying Instantaneous Value

An experimental single-anode mercury arc valve was constructed containing a low-heat-resistance pool cathode of the molybdenum-cup type[1] to anchor the cathode spot and a plasma probe inserted with its tungsten tip at the axis of the valve at a distance about one-third from anode to cathode. The valve was operated in a resistance-loaded single-phase half-wave rectifier circuit, thus carrying a half-period sinusoidal current at a frequency of 50 c/s. The cathode temperature of the valve, and hence its saturated vapour pressure, was adjusted by a control of air flow from a fan below the cathode, and the pressure was thus varied over a range of 2·5–17·5 μm mercury. The crest value of current through the valve was altered by changing the load resistance. Further on, a modified version of plasmograph[2] was constructed to obtain on a cathode-ray tube screen a trace in semi-logarithmic form of the probe characteristic at any chosen instant of the wave-shape of the current pulses passing through the valve. Probe characteristics were obtained to construct sets of characteristics of the plasma parameters as functions of the instantaneous values of current i_a for different values of load resistance at a fixed cathode temperature, and for different values of cathode temperature at a fixed value of load resistance.

Fig. 1 shows the typical shape of a dynamic characteristic of electron density, n_e, as a function of the instantaneous value of i_a, and it also indicates the general tendency for the shape of ion density, n_i. Thus $n_e = n_e' + \Delta n_e$ and $n_i = n_i' + \Delta n_i$ where $n_e' \neq n_i'$ each depending only on the instantaneous value of i_a, and where Δn_e and Δn_i are each dependent both on i_a as well as on the magnitude and sign of its rate of change di_a/dt. The condition $di_a/dt > 0$ causes Δn_e and Δn_i to have negative values, that is, in Fig. 1 $n_e < n_e'$ and $n_i < n_i'$ for rising instantaneous values of current, and the condition $di_a/dt < 0$ causes Δn_e and Δn_i to be positive, that is, in Fig. 1, $n_e > n_e'$ and $n_i > n_i'$ for falling instantaneous values of current. The absolute values in both cases are throughout $|\Delta n_i| > |\Delta n_e|$. Thus the hysteresis effect which occurs for each density is greater for the ion density than for the electron density. At this stage no mechanism is proposed to explain the cause of the two effects apart from suggesting the possibility of some influence derived from delayed ionization as a result of collisions of pairs of metastable excited atoms[3].

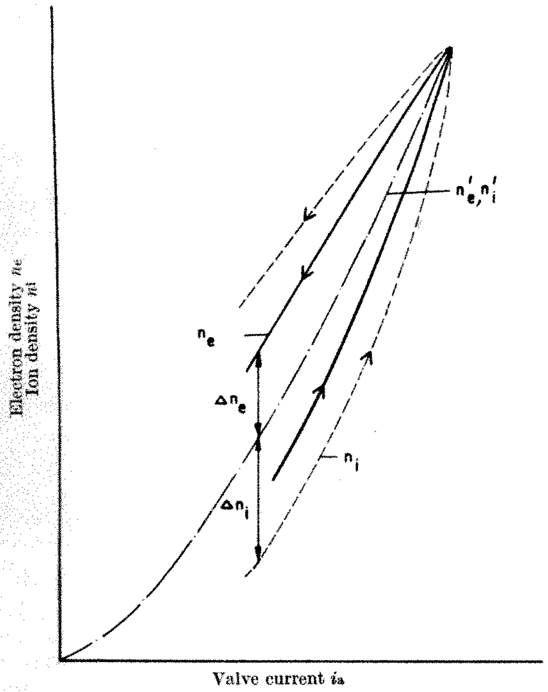

Fig. 1. Typical shapes of the dynamic characteristics for the electron and ion densities

This work was carried out in the Electrical Engineering Department of the Manchester College of Science and Technology. We thank Dr. H. Adam for providing essential parts for the construction of the experimental valve.

Dry Flotation

A factor of major importance in the concentration of fine mineral particles by the process of froth flotation is the high moisture content of the final vacuum-filtered product. This is especially the case for coal flotation concentrates which contain more than 20 per cent of moisture. Potential savings in thermal efficiency and freight initiated research in this field.

Since successful flotation of selected minerals and coal was possible following dry conditioning (private communication from the Department of Mineral Technology, Imperial College of Science and Technology, London), it appeared reasonable to consider attempting flotation without proceeding to wet the hydrophobic surface induced by conditioning. Of the methods so far investigated the most successful has been the use of hydrocarbons having a low boiling point.

Samples of coal were conditioned with pentane and after pulping fed into a flotation cell. The cell was heated, externally, causing vaporization (a form of spontaneous aeration) of the pentane. Since this vaporization occurred at the surface of the coal adhesion or contact occurred and the composite of coal and hydrocarbon vapour rose to the surface, forming an agglomeration of particles similar to the froth obtained in normal flotation operations. Particles of impurity, such as shale, were released from the bubbles of vaporized pentane which occurred at their surface and, since adhesion did not take place, the shale remained in the pulp body of the cell.

The froth concentrate was collected and filtered and as a result of the non-wetting of the particles the moisture content of the product was less than 10 per cent, an appreciable improvement over that achieved by conventional flotation–filtration procedure. Subsequent tests were made using low-octane petrol as a substitute for pentane. Comparable results were obtained.

To overcome the necessity of heating the pulp body, an alternative procedure was to induce vaporization of the hydrocarbon by pressure reduction. Following conditioning, samples were floated by inducing vaporization in a vacuum type flotation cell. Results were similar to those obtained using the pulp-heating process.

Initial experiments indicated that similarly successful flotation was obtainable for the mineral galena provided that the process consisted of collector coating followed by conditioning with hydrocarbon and vacuum or elevated temperature flotation.

Samples of coal concentrate obtained by conventional flotation were vacuum filtered and washed with pentane. The final moisture content was less than that obtained by normal processes but greater than for hydrocarbon vacuum flotation. Work on samples of galena gave similar results.

It would appear that, following activation, conditioning with hydrocarbon prevents the particle from becoming water wetted and permits bubble attachment to a relatively dry particle. The gaseous film reduces subsequent wetting during froth collection and filtration. The alternative of replacing the water film during filtration was less successful.

The process as discussed permits an increased volume of bubbles to be obtained in vacuum flotation giving better aeration of the cell volume. Recovery and re-use of the hydrocarbon used is possible by collection of the vapour from the flotation cell and filters and liquefying.

Work completed so far must be considered as an initial approach to the problem of lower moisture contents in concentrates. Since comminution and conditioning may be achieved efficiently in the dry state it seems desirable to control flotation so that the economic mineral is not water wetted, only the gangue minerals being so affected.

Further work is being planned to examine this process and to assess its potentialities.

METALLURGY

High-Frequency Chromizing

In recent years new processes involving the use of a medium containing 75 per cent chromium with 25 per cent cryolite and high-frequency heating have been developed for the chromizing of ferrous and non-ferrous metals[1–4]. Generators operating with frequencies of 3–3·5 Mc/sec have been used, and it has been claimed that coatings which would require the treatment of mild steel for at least 30 min at 1,200° C can be produced in 60–80 sec with high-frequency heating. Under these conditions the estimated temperature at the surface of the specimen during inter-diffusion was 1,250° C. Enhanced diffusion-rates under high-frequency heating conditions have been claimed and it has been suggested that there may be some 'high-frequency effect' in such processes. Specimen surface temperatures have been measured during recent investigations, and the results shed some light on this problem.

Twelve mild-steel specimens 0·125 in. in diameter and 2 in. long were placed in the chromium–cryolite medium contained in the annulus between two concentric cylinders (Fig. 1). Both ends of the annulus were sealed with refractory cement and the apparatus placed in the high-frequency coil. This apparatus allowed the preparation of sound chromized coatings and gave reproducible results. Specimen surface temperatures were measured during chromizing with the following arrangements of cylinders (Fig. 1): (*a*) both cylinders of refractory material; (*b*) outer cylinder of refractory, inner mild steel; (*c*) both cylinders of mild steel.

Fig. 1. Concentric cylindrical apparatus developed for chromizing

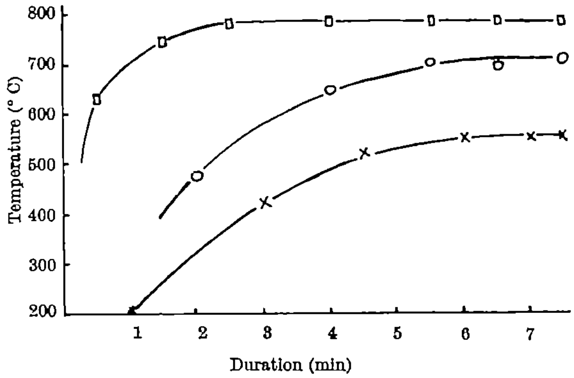

Fig. 2. Temperature distribution as a function of duration of heating (using two silica cylinders). ×, Unprotected *T/C* in the medium; □, specimen *T/C*; ○, sheathed *T/C*

Platinum–platinum rhodium thermocouples were sited in the annulus as follows: (1) unprotected in the chromizing medium approximately 0·2 in. from the nearest specimen; (2) unprotected, welded to 0·125 in.-diameter specimen; (3) protected by a thin silica sheath placed in the medium.

A typical set of heating curves for arrangement (*a*), that is, the all-refractory system, is given in Fig. 2. Here, even with twelve specimens in position the maximum surface temperature achieved was about 790° C. It is of significance, however, that this temperature was ~230° C greater than the temperature of the chromium–cryolite medium. With arrangement (*b*), the inner wall of the steel cylinder reached the greatest temperature, 1,150° C, closely followed by that of the specimen surface. The maximum temperature in the medium was approximately 1,060° C. There was no significant difference in temperature between that of the inner cylinder, the specimen surface and the medium when arrangement (*c*) was used. A temperature of 1,400° C was obtained with this arrangement.

These experiments indicate that when specimens are heated by induced eddy currents, arrangement (*a*), the true specimen surface temperature can be at least 230° C higher than that of the chromizing medium. In the case of arrangement (*c*) the specimens will be heated mainly by conduction of heat from the walls of the steel cylinders through the medium, and here the temperatures of the medium and of the specimen surfaces are the same. This corresponds more closely to the conditions encountered in conventional chromizing processes. Since chromizing temperatures in high-frequency chromizing processes have, hitherto, been measured with optical pyrometers[1,3] it seems likely that such temperatures will correspond more closely to those of the medium than those of the specimen surfaces. This is illustrated in Fig. 3, in which diffusion coefficients calculated from the data of Minkevitch and Ulybin for the chromizing of low

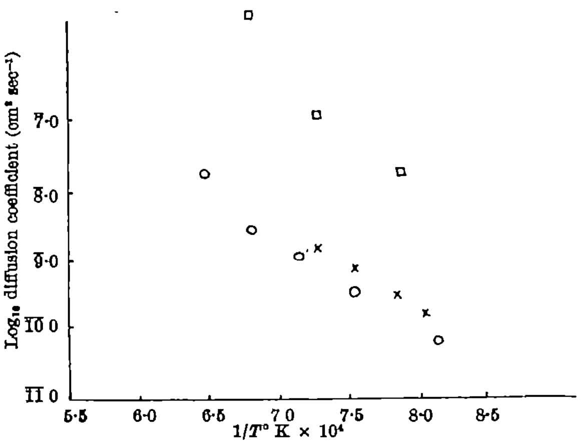

Fig. 3. Comparison of the diffusion coefficients for the chromizing of low carbon steels by conventional and high-frequency techniques
☐, High-frequency, techniques 0 2 per cent carbon steel (ref. 3);
×, conventional techniques with 0 1 per cent carbon steel (ref. 6);
○, present work using cylindrical arrangement (c) on 0·16 per cent carbon steel

carbon steels under high-frequency conditions (3·5 Mc/sec) are compared with values obtained in recent work[5] using arrangement (c) and those of other authors[6] using conventional techniques. The values of the diffusion coefficient from the results of Minkevitch and Ulybin at 1,000° C correspond to values obtained in recent work at ~1,260° C. This suggests that the temperatures at the specimen surfaces in the high-frequency process were about 260° C higher than the nominal chromizing temperature. This is much greater than the value of 100°–125° C suggested by Minkevitch and Ulybin and corresponds more closely to the value of 230° C found in the present work in which a generator of lower frequency (1 Mc/sec) was used.

This investigation strongly suggests that the apparently high inter-diffusion coefficients obtained during high-frequency chromizing arise because of unsuspectedly high temperatures at the specimen surfaces. This alone would be sufficient to create the required additional vacancies in the alloy lattice and would obviate the need to ascribe enhanced diffusion-rates to some unknown 'high-frequency effect' as has been suggested[3].

RADIATION CHEMISTRY

Annealing Behaviour of Phosphorus-32 Recoils in Potassium Chloride Crystals

THE behaviour of radioactive species, formed by neutron capture in crystals, as a function of post-irradiation annealing treatment has been extensively studied for central atoms in oxy-anions[1,2]. So far as we are aware, in only one case have annealing curves shown a lowering of the valency of the activated atom in the species resulting from dissolution of the crystal, namely in the case of the $^{75}As(n,\gamma)^{76}As$ reaction in As_2O_3 and $NaAsO_2$ (ref. 3). In most cases

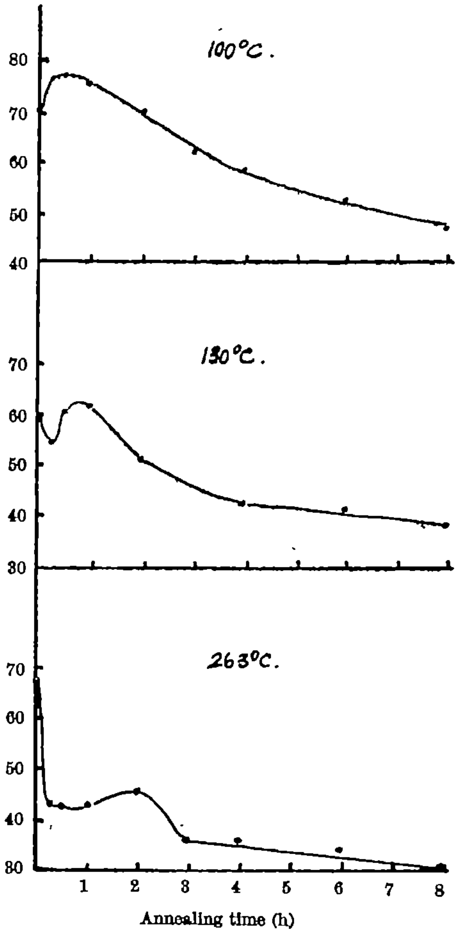

Fig. 1. Percentage of lower-valency phosphorus-32 as a function of time in pile-irradiated crystals of potassium chloride at annealing temperatures of 100° C, 130° C and 263° C

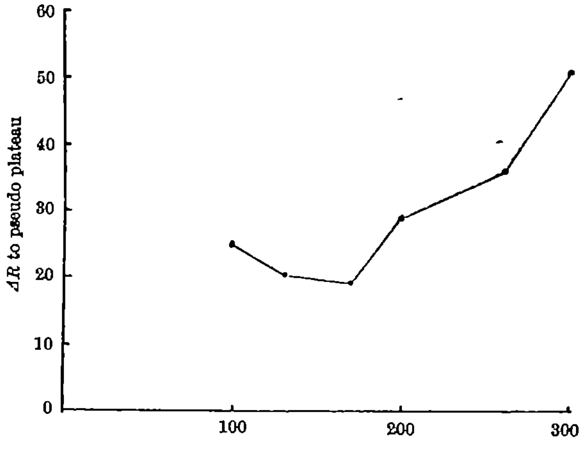

Fig. 2. Change in percentage lower-valency phosphorus-32, ΔR, from non-annealed value to pseudo-plateau value, as a function of annealing temperature

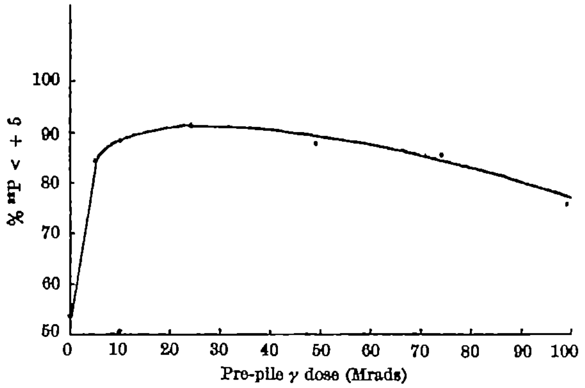

Fig. 3. The effect of γ-irradiation of potassium chloride targets, prior to pile irradiation, on percentage of lower-valency phosphorus-32

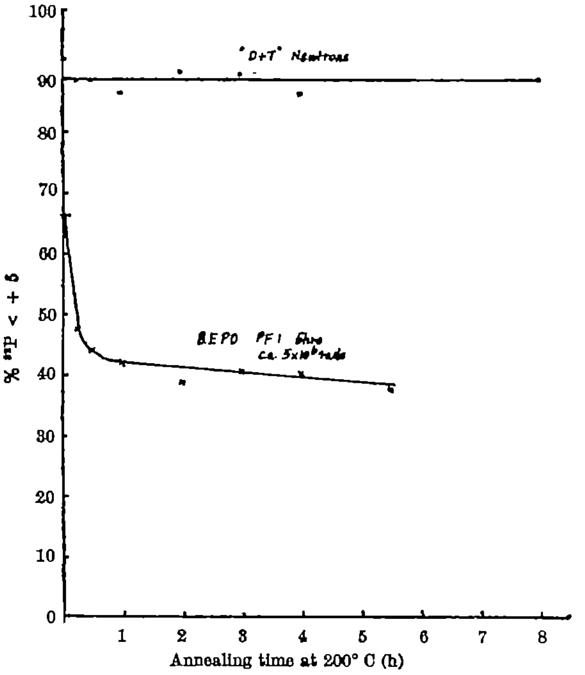

Fig. 4. Percentage lower-valency phosphorus-32 as a function of annealing time in potassium chloride crystals irradiated with pile neutrons and 14·1 MeV D + T neutrons

there is a rapid rise in oxidation state of the radioactive species followed by a further slow rise or pseudo-plateau. Süe and Caillat[4] found that heating neutron-irradiated sodium chloride for a few minutes to 350° C caused a significant increase in the proportion of lower-valency phosphorus-32. Since the colour of the irradiated crystals was simultaneously discharged they suggested that electrons from *F* centres might be effecting the reduction of phosphorus-32 + 5 species.

We have found evidence for a reductive reaction involving phosphorus-32 recoils during the thermal annealing of pile-irradiated potassium chloride crystals. In this work we have simply separated ^{32}P $\leqslant +3$ from higher valency forms by magnesium ammonium phosphate precipitation. Fig. 1 shows that superimposed on the normal fast and slow oxidative reactions there is a fairly fast reduction reaction, appearing as a hump on the curves. Fig. 2 shows a plot of the change in percentage lower-valency phosphorus-32 from the non-annealed value to the value at the pseudo-plateau plotted against the annealing temperature. A linear relationship is often obtained for this plot when $1/T$ is used, interpreted by the Maddock–de Maine annealing model[1–5]. In the present case, however, the curve is fairly flat up to 170° C after which it begins to rise, suggesting that in the region up to 170° C a reducing reaction involving the recoils is competing with the more normally observed oxidation reactions. Kobayashi[6] concludes from his work on proton-irradiated sodium chloride crystals that *F* centre discharge commences at about 100° C and is occurring extensively in the range 150°–170° C. It thus seems likely that electrons from *F* centres are reducing phosphorus-32 species in the lattice which would otherwise yield P + 5 compounds on solution of the crystal.

It has recently been reported[2] that irradiation of chromate crystals with 1·8-MeV electrons prior to pile irradiation significantly increases the proportion of chromium-51 atoms in lower valency states. Fig. 3 shows the results of irradiating potassium chloride crystals with varying doses of γ-rays from spent reactor fuel in the Harwell irradiation pond prior to a pile irradiation in *Bepo* involving a ~5 Mrads additional γ-dose. It can be seen that a pre-pile dose as small as 5 Mrads can significantly increase the proportion of lower valency phosphorus-32. This pre-pile irradiation effect appears to have very nearly reached saturation with a dose of 5 Mrad. There is some evidence from this figure that there is a slight rise to maximum lower valency phosphorus-32 at a γ-dose of ~24 Mrads, followed by a small decline. The pre-pile γ-radiation lowering of phosphorus-32 valency state is probably due to encountering of *F* centres during the recoil or to discharge of *F* centres in the 'hot zone' formed in the terminal region of the recoil track[7].

Fig. 4 shows the effects of thermal annealing of potassium chloride irradiated with neutrons from the pile and from a D + T source. In the case of the virtually γ-free D + T neutrons, there is very little annealing, while in the case of the pile irradiation a normal two-phase oxidative annealing reaction occurs. This finding lends rather striking support to the recent suggestion that lattice defects may be responsible for annealing reactions[3]. The interesting feature of the present case, however, is that the defects or radicals generated along the recoil track are not able to take part in oxidative annealing, whereas defects induced by radiation in the bulk of the crystal can allow such reactions to occur. There seems to be a difference in behaviour between recoil-induced defects and radiation-induced defects in this system.

Phosphorus-32 recoils in potassium chloride crystals would seem to provide useful material for studying oxidation-reduction reactions between polyvalent atoms and lattice defects.

CHEMISTRY

Substrate Cleavage Point with Glucamylase

THE glycosidic link can, theoretically, be hydrolysed by two alternative routes, proceeding with the fission of the bond between (*a*) the anomeric carbon atom and the glycosidic oxygen or (*b*) the aglycon group and the glycosidic oxygen. For a number of glycosides the mechanism of the acidic and/or enzymatic hydrolysis has been investigated[1-8]. Since it became possible to prepare highly purified glucamylase it was interesting to investigate the cleavage point when this enzyme acts on maltose.

An aqueous extract (8 ml.)[9] of ruptured *Aspergillus niger* '152' cells was fractionated on a column (29 × 1·5 cm) of diethyl-amino-ethyl cellulose (Whatman *DE* 50) by the method of Pazur and Ando[10], using the same citric acid phosphate buffer but a smaller *p*H gradient for elution. Elution was commenced with buffer solution (100 ml.) of *p*H 7·5 and followed successively with the same volume of buffer solutions of *p*H 7·0 and 6·5. Fractions of the eluate (5 ml.) were analysed for transglucosylase and glucamylase activity by incubating portions in digests containing (*a*) amylose and (*b*) maltose. Transglucosylase activity was found in fractions No. 13–16 and glucamylase activity in fractions No. 14–20. Fractions No. 17–20 contained glucamylase activity only. The iodine-absorption value reducing power curve[11] of the pure glucamylase fraction was found to be identical with that of glucamylase purified by acid treatment[9] and remained unaltered after such treatment.

The point of cleavage of the α-1 : 4-glucosidic link when glucamylase acts on maltose was investigated by conducting the hydrolysis in $H_2{}^{18}O$.

The enzymatically produced glucose was isolated as its phenylosazone. Thus, fission of the $C_{(1)}$-O bond, route (*a*), would lead to a glucosazone, all oxygen atoms of which would be isotopically normal, whereas fission of the $C_{(4)}$–O bond, route (*b*), would give a glucosazone, one oxygen atom of which would be isotopically half-enriched.

A digest containing maltose (112 mg) in $H_2{}^{18}O$ (1·5 ml.; oxygen-18 enrichment 4·2 per cent), M-acetate buffer (*p*H 4·0; 0·1 ml.) and glucamylase solution (0·4 ml.) was incubated at 50° C for 16 h, when all the maltose had been hydrolysed to glucose. This was isolated as its phenylosazone with m.p. 204°–205° C which was not depressed on admixture with authentic glucosazone. A control experiment was carried out in normal water. Samples of glucosazone were pyrolysed by a method similar to that described by Oita and Conway[12]. Mass-spectrometric analysis of the carbon dioxide obtained showed no enrichment in oxygen-18.

The results show that the hydrolysis of maltose by glucamylase proceeds almost entirely by the fission of the bond between the anomeric carbon atom and the glycosidic oxygen. This is in contrast to the acidic hydrolysis of maltose where 78 per cent of the reaction apparently proceeds by this route[8]. On the other hand, with few exceptions such as the hydrolysis of α-D-glucose-1-phosphate by prostatic acid phosphatase[4], enzymatic reactions studied seem to proceed by route (*a*). Thus, the hydrolysis of maltose by glucamylase follows a general pattern for hydrolases and transglycosylases.

We thank Prof. E. J. Bourne for his interest, the Department of Scientific and Industrial Research for financial assistance, Dr. C. A. Bunton for a gift of oxygen-18-enriched water, and Dr. G. Majer for assistance with isotopic analysis.

'Filterscan'; a Novel Technique in X-ray Fluorescence Analysis

NOTABLE successes in recent years have attended the development of X-ray fluorescence in the field of spectrochemical analysis[1]. The versatile and non-destructive methods which have ensued are conventionally based on the dispersive principle in spectrometers which are equipped with crystal monochromators.

The non-dispersive modification proposed here, however, not only offers marked simplification by avoidance of the analysing crystal but also a straightforward resolution of elements of adjacent atomic number. The underlying principle[2] is based on the fact that radiation from an element of atomic number Z passes much more readily through a filter composed of element Z–1 than through a filter Z–2. For example, copper ($Z = 29$) $K\alpha$-radiation passes very strongly through nickel ($Z = 28$) foil, but weakly through cobalt ($Z = 27$) foil (Fig. 2).

The procedure is to place filters successively in the path of the specimen's excited fluorescent X-rays. Measurements of the transmitted radiation intensity result effectively in a scan of the absorption edges of the incident radiation, providing dispersion in a manner alternative to that of the crystal spectrometer or pulse-height analyser[3].

Since a sequence of interchangeable filters is a feature which, so far as I am aware, lends novelty to this method, the term 'Filterscan' is proposed for its description.

Hitherto, non-dispersive methods[4] have been capable of resolving elements of adjacent atomic number but only at the expense of elaborate and costly electronic discriminating circuitry. The 'Filterscan' method involves relatively inexpensive equipment. Moreover, the technique proposed here differs from the majority of previous absorption methods[5,6] in that the absorption process is divorced from the sample and complete control over the absorption is thereby achieved. In addition, because a radioactive source is used, there is no problem associated with source instability, the exponential decay factor being readily assessable.

The arrangement shown in Fig. 1 has been found to be practicable, in which *A* is a radioactive X-ray source chosen to give sufficient energy to excite the elements of interest in the sample at *B*. Fluorescent radiation excited in the sample is detected by the end-window Geiger–Müller counter *GM* after passing through the interchangeable filter *F*. The filters consist of elements of suitable consecutive atomic numbers and are similar in their absorption properties to conventional β-filters as used in X-ray diffraction.

By plotting the filter used against transmitted intensity a discontinuity or step is revealed as each absorption edge is passed. Fig. 2 illustrates this effect in the case of solid copper and yellow-brass samples (approximately 70 per cent copper, 30 per cent zinc) where the two steps due to the copper *Kα*-radiation are seen to be in approximately the correct ratio.

Aqueous solutions of manganese dichloride, examined over the range from 21·0 to 0·66 per cent w/v manganese, yield a satisfactory working curve (Fig. 3).

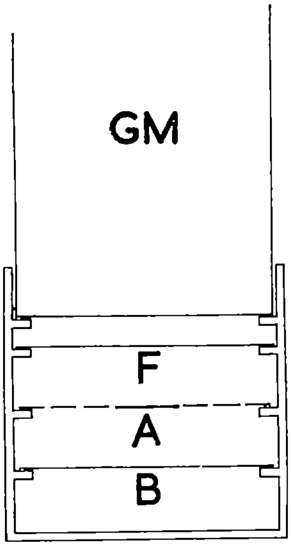

Fig. 1. 'Filterscan' housing showing radioactive source *A*; specimen *B*; interchangeable filter *F*; end-window Geiger–Muller counter *GM*

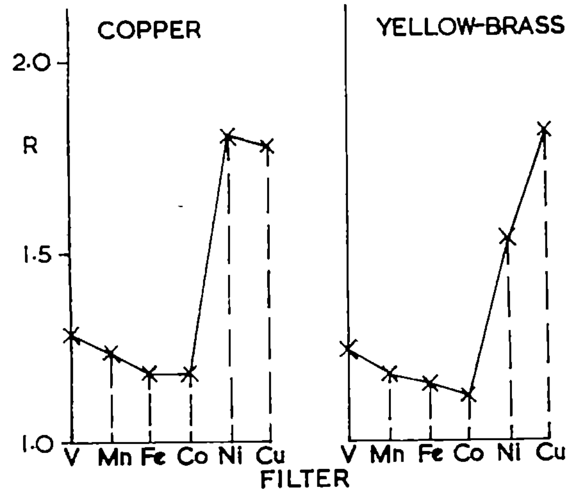

Fig. 2. Scans produced from copper and yellow-brass specimens.

$$R = \frac{\text{counts/10 sec (sample)}}{\text{counts/10 sec (Al blank)}}$$

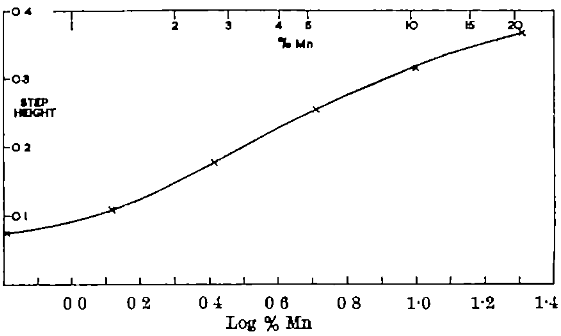

Fig. 3. Working curve for aqueous manganese dichloride solutions

Step height = *P* (Mn) – *P*(V)

$$P = \frac{\text{time for 4,000 counts (Al blank)}}{\text{time for 4,000 counts (sample)}}$$

Further refinement will be possible by using a scintillation counter in place of the end-window Geiger-Müller counter. It is anticipated that greatly improved sensitivity will be thereby achieved.

High-resolution Nuclear Magnetic Resonance Spectrum of a Methanol Lignin

A SAMPLE of methanol lignin from *Eucalyptus regnans*[1], purified by counter-current distribution and possessing the empirical formula (on the basis of a C_9 unit) of $C_9H_{8\cdot1}O_{2\cdot70}(OCH_3)_{1\cdot86}$, was examined by means of the high-resolution nuclear magnetic resonance technique. This lignin was shown to contain approximately equal numbers of guaiacyl and syringyl units and to have been methylated to the extent of 0·41 methoxyl groups per C_9 unit[1]. The spectrum (Fig. 1) of an approximately 10 per cent solution in deuterochloroform was recorded on a Varian model *A*60 spectrometer operating at 60 Mc/s and was calibrated in parts per million from tetramethyl silane as internal reference[2]. The feature centred at 6·62 p.p.m. can be attributed to protons linked directly to aromatic nuclei and that centred at 3·85 p.p.m. to protons in methoxyl groups. When recorded under the same conditions the spectrum of vanillin showed the methoxyl feature at 3·88 p.p.m. and that of syringaldehyde at 3·93 p.p.m. In the foregoing empirical formula, hydrogen present as methoxyl accounts for about 41 per cent of the total, whereas the feature at 4·98–3·45 p.p.m. equals 46 per cent of the total. The remaining features are most likely to be mainly associated with protons attached directly to oxygen (hydroxyl groups) or to carbon atoms bearing negative substituents. Protons resonating at corresponding frequencies may be found in the spectra of lignans[3,4]. There is a striking lack of features upfield from 2 p.p.m. where most aliphatic and alicyclic methyl, methylene and methine protons would be expected to occur[5]. In general, the proton

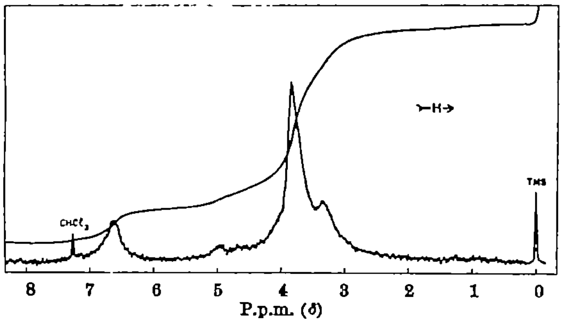

Fig. 1. Nuclear magnetic resonance spectrum of methanol lignin

magnetic resonance spectrum appears to be in agreement with the type of structure predicted by Freudenberg[6].

The relative proportions of protons in different environment were estimated by integration and the aromatic protons were found to account for 13·4 per cent of the total. With half the units of the guaiacyl and half the syringyl type in the empirical formula quoted here, the aromatic protons should have accounted for 18·3 per cent of the total if no coupling directly to the aromatic nuclei had occurred. This discrepancy can be interpreted as signifying that approximately 27 per cent of the units present are coupled in this manner. This figure then represents the total number of aromatic nuclei involved in 'condensed units', that is, aryl–aryl and aryl–alkyl linkages. As these linkages are believed to occur ortho to the phenolic group the syringyl nuclei could not take part. This result suggests that about 54 per cent of the guaiacyl nuclei are so linked. This appears to be in agreement with the type of lignin structure proposed by Adler[7] for softwood lignin. The remaining protons are distributed in the following way (region in p.p.m.): per cent of total protium—(6·0–4·98): 18, (3·45–2·12): 20, (2·12—10): 2·6. Part of the signal contributing to the pronounced feature at 3·35 p.p.m. may be due to hydroxyl protons, as it was affected by treatment with deuterium oxide[8].

BIOPHYSICS

Efflux of Chloride Ions during the Action Potential of *Nitella*

This communication is prompted by a report of Spyropoulos, Tasaki and Haywood[1] that they were unable to confirm the findings of Gaffey and Mullins[2] that in *Chara* there is an efflux of chloride ions during an action potential. It would appear, however, that the experimental conditions of Spyropoulos *et al.* were not such as to make a demonstration possible. This is shown by the following calculations. A *Nitella* cell, 0·06 cm in diameter by 4 cm in length, has a volume of 0·011 cm^3 and very nearly 0·66 cm^2 of surface area. The volume of the cell is nearly all sap and if its [Cl] is taken as 100 µmole/cm^3 then a cell contains 1·1 µmole Cl^-. With a membrane capacity of 1 µF/cm^2 and an action potential of 100 mV, 1×10^{-12} mole of Cl^- must be lost to produce the potential change, per cm^2 or 0·66 pmole for the *Nitella* cell. The cells used by Spyropoulos *et al.* had 1,000 c.p.m. chlorine-36 and 1 µmole Cl^-, so that each c.p.m. represented 10^{-9} mole Cl^- and the expected loss for an action potential is about 1/1,000th of a c.p.m. Forty stimuli were delivered—this would increase the efflux but the efflux was collected in 20 fractions so that the total efflux to be expected for the experiment would be 2/1,000ths of a c.p.m. in each fraction. In the experiments with *Chara*[2] the quantities of Cl^- lost were 500–5,000 times greater than that calculated above and were equivalent to K^+ loss, while the action potential was 200 mV, or considerably greater than that in *Nitella*. The K^+ loss demonstrated by Spyropoulos *et al.* ought to equal Cl^- loss, but in the absence of information on the specific activity of their potassium-42 in the cell no calculation is possible. The specific activities of potassium-42 and chlorine-36 as supplied by the Atomic Energy Commission, Oak Ridge, are as 2,000 : 1, and for equal loading times the intracellular potassium would be preferentially labelled. What does seem clear is that the extent to which cells were labelled with chlorine-36 was inadequate to detect an extra efflux of activity (over the resting Cl^- efflux and over background).

Two other reports[3,4] suggest that in *Chara* and *Nitella* the action potential is brought about by an inward movement of Ca^{++}. There is no evidence from isotope studies that this is so, and the authors argue from the point of view of the bioelectric effects of Ca^{++}. They are both apparently unaware of the work of Frankenhaeuser and Hodgkin[5] on the squid axon and of much other work showing that increases in $[Ca]_0$ act like increases in membrane potential in: (*a*) diminishing K^+ conductance at rest; (*b*) in making available a greater passive movement of Na^+ during a subsequent depolarization. In *Chara*, hyperpolarization clearly increases spike height, and the observation of Hope that increases in $[Ca]_0$ enhance spike height are not a convincing demonstration that calcium ions carry the depolarization current. The observations of Findlay are with *Nitella* under voltage clamp conditions. These show precisely the sort of effects one might expect if the action of Ca^{++} were to activate a greater fraction of the mechanism responsible for Cl^- movement subsequent to depolarization. Two different Cl^- concentrations were used, 0·1 and 1·0 mM, presumably as a test of the extent to which the chloride equilibrium potential would be shifted by such a concentration change. It is important to note that such evidence as there is suggests that the equilibrium potential of an ion is not a very useful concept when the concentration ratio across the membrane exceeds perhaps 50 because the contributions of current from other ions tend to act as shunts in the system. With $[Cl]_i = 100$ mM, and a clamped depolarization to zero membrane potential, the chloride current would be expected to be proportional to 100–1 and 100–0·1 for the two concentrations used. One must conclude, therefore, that the two currents responsible for depolarization and repolarization in

Nitella have not been resolved in this voltage clamp study.

Because Cl^- efflux during an action potential has not been demonstrated in an ecorticate *Nitella* cell, it seemed valuable to make such measurements. Internodal cells of *Nitella clavata* (strain *XO*-33) from cultures maintained in the laboratory under controlled conditions of light and temperature (I am indebted to Dr. Charles Barr for the cells used) were obtained and were loaded for 30 days with chlorine-36. The loading solution contained sodium chloride 15 mM, potassium chloride 0·1 mM, and calcium chloride 0·1 mM, and its specific activity was 0·3 mc./g chloride. After loading, the cell sap had a specific activity of 0·3 that of the loading solution. Such cells were transferred to 1 litre of a solution containing 1 mM sodium chloride, 0·1 mM potassium chloride and 0·1 mM calcium chloride. Cells were washed for 24 h in 2 changes of this solution and were then mounted in a glass experimental chamber containing 4 gold electrodes (2 for stimulating and 2 for recording), and 5 ml. of the 1 mM sodium chloride solution. Exhaustive tests were made for any evidence that the metal electrodes might in any way alter either the electrical properties of the cells or the resting efflux of chlorine-36. These tests showed that both threshold and spike amplitude were unchanged after cells had spent 48 h in the chamber; similarly, chlorine-36 efflux was unchanged after a similar period of time. As a final check, sub-threshold stimulation with 0·1 msec shocks at 1/min failed to alter the resting chloride efflux. On the other hand, a single conducted action potential sufficed to double the rate constant for chlorine-36 efflux during a 15-min collecting period. Resting effluxes were of the order of 2–4 c.p.m. per hour of efflux and all counts were made in an automatic sample-changing flow gas counter with an anti-coincidence guard. Background was 2 c.p.m. and at least 1,000 counts over background were obtained on each sample measured. Some results obtained are shown in Fig. 1, where the rate constant for loss of chlorine-36 is plotted against time. In all experiments there was a 1 h resting efflux collection before stimulation and in one case the cell was maintained in the chamber for 24 h after stimulation and efflux was measured again. Stimulation was effected with 0·1 msec square wave pulses, with an amplitude roughly twice threshold; usually 15–17 stimuli were given during 15–20 min. It is clear that stimulation leads to a large increase in the rate constant for loss of chlorine-36 from the cells and that this increased rate of loss subsides to resting values within 30 min after stimulation. The delay in efflux of chlorine-36 from the cell may be because the cell wall is a cation exchange system with a low anion permeability. The absolute values of efflux for the 5 cells used are shown in Table 1. Values for resting efflux are within the range of values previously given for *Chara*[2] while values for the stimulated efflux, although large, are somewhat smaller than those for *Chara*. The difference may be due to the rather different duration of the action potential (10 sec for *Chara*, 2·5 sec for the species of *Nitella* used in this investigation). What is important is the clear demonstration of an efflux of chlorine-36 about 1,000-fold greater than that necessary to bring about the bioelectric activity that is observed.

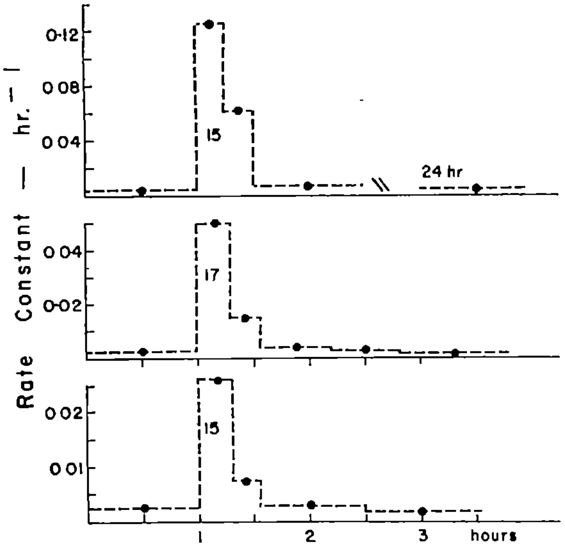

Fig. 1. The rate constant for efflux of chlorine-36 is shown as a function of time for three cells. All cells had a 1-h rest period and were then stimulated; the numbers on the graph indicate the number of such stimuli. In the chart at the top, the cell remained in the chamber for 24 h after the last sampling and the rate constant for efflux during this period is shown

Table 1. Efflux of Chlorine-36 from *Nitella* at Rest and during Stimulation

Cell No.	Resting efflux (pmole/cm² sec)	Stimulated efflux (pmole/cm² impulse)	Ratio: rate constant during stimulation/ rate constant at rest
1	1·0	8,000	41
2	1·2	1,350	31
3	1·0	1,220	25
4	1·0	540	15
5	3·1	870	20

BIOCHEMISTRY

A Rapid Enzymatic Assay for Glycerol

Enzyme methods for the assay of glycerol using glycerol dehydrogenase[1] or glycerol kinase with L-glycerol 1-phosphate dehydrogenase[2] and based on the reduction of NAD to $NADH_2$ (measured by change in extinction at 340 mμ) have the disadvantage that the reaction time is comparatively long (about 30 min). An alternative and more rapid method has been developed which is based on the following reactions:

glycerol + ATP ⇌ L-glycerol 1-phosphate + ADP (glycerol kinase)

ADP + phosphoenolpyruvate ⇌ ATP + pyruvate (pyruvate kinase)

pyruvate + $NADH_2$ ⇌ lactate + NAD (lactate dehydrogenase)

The phosphorylation of glycerol is coupled with the oxidation of $NADH_2$ which may be followed spectrophotometrically at 340 mμ. At *p*H 7·6 the forward reaction is favoured in each case and hence rapid and complete assay of glycerol may be made. Under the conditions to be described the assay reaction for glycerol (in the range 0·005–0·05 μmole) is complete in 3–5 min.

The reagents required for assay were obtained from C. F. Boehringer und Soehne through Courtin and Warner, Ltd., Lewes. It was convenient to prepare stock solutions of 75 mM ATP disodium salt; 3 mM NADH$_2$; and 0·1 M triethanolamine hydrochloride (adjusted to *p*H 7·6 with saturated NaOH) containing 6 mM magnesium sulphate, 2 mM potassium chloride, and 7 mM phosphoenolpyruvate tri*cyclo*hexylammonium salt. These solutions may be stored at − 15°. An assay mixture is prepared by adding 0·25 ml. of ATP solution, 500 μg of pyruvate kinase and 200 μg of lactate dehydrogenase to 10 ml. of triethanolamine buffer, magnesium sulphate, potassium chloride. phosphoenolpyruvate solution. In general sufficient NADH$_2$ was added to give an extinction of 0·8 at 340 mμ in a 1-cm light path when the assay mixture is read against a water blank (1 ml. of stock NADH$_2$ solution added to above assay mixture). The quantity of NADH$_2$ may need to be increased if the sample for glycerol assay contains much pyruvate or ADP. Samples of blood plasma or incubation media or tissue extracts for glycerol assay may be deproteinized with an approximately equal volume of 10 per cent trichloroacetic acid and the latter removed by extracting thrice with a five-fold excess of ether and the ether removed by suction and *in vacuo*. The ether extraction concentrates glycerol and other ether insoluble components by a factor of 1·15 due to the removal of water in the ether phase, and this can be allowed for in calculating the results. Extracts deproteinized with perchloric acid were found to be unsuitable for assay of glycerol since they inhibited pyruvate kinase.

Assays were performed in quartz cells with a 1-cm light path. To 1 ml. of assay mixture is added 1 ml. of sample for glycerol assay (containing 0·01–0·1 μmole glycerol) and the change in extinction due to reaction of pyruvate or ADP in the sample allowed to complete. The change in extinction due to glycerol is then measured following the addition of 10 μg of glycerol kinase.

Typical progress curves with standard glycerol solutions are shown in Fig. 1. The reaction is complete within 1–2 min under these conditions but with plasma extracts 3–5 min is required for completion. Over a range of glycerol concentrations in the assay cuvette of 0·01–0·05 μmole/ml., change of extinction at 340 mμ and glycerol concentration are linearly related and the observed change in extinction is in good agreement with that calculated from the molar extinction of NADH$_2$. The glycerol concentration may be calculated, therefore, from the change in extinction, the molar extinction of NADH$_2$ and relevant dilution factors. The recovery of glycerol added to human blood plasma before deproteinization (amounts 0·025–0·125 μmole of added glycerol per ml. of plasma) gave a mean value of 0·95 ± 0·018 (mean ± *S.E.*). Recovery was thus substantially complete.

Dihydroxyacetone and L-glyceraldehyde are also assayed by this method, but under the conditions used the initial velocity with glycerol as substrate is approximately forty times greater than with similar concentrations of the other substrates.

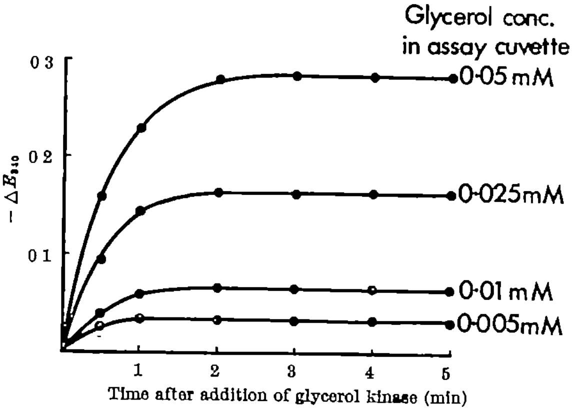

Fig. 1. Time course of reaction

The method can be readily applied to the estimation of glycerol in blood plasma or for measurement of glycerol output by isolated tissues. With this method the mean plasma glycerol concentration in five normal adult males after an overnight fast was 48 ± 4 μmoles/l. and under similar conditions a group of 43 untreated diabetics had a mean plasma glycerol concentration of 90 ± 6 μmoles/l. (mean ± *S.E.*). The outputs of glycerol by perfused heart, isolated diaphragm and isolated epididymal adipose tissue from normal rats were (μmoles/g/h mean ± *S.E.*) 2·7 ± 0·21, 0·66 ± 0·09, 0·87 ± 0·05, and from alloxan diabetic rats 4·6 ± 0·22, 1·15 ± 0·12, 1·26 ± 0·03 (6 tissues in each group).

We thank the British Diabetic Association and the British Insulin Manufacturers for grants which contributed to the cost of this investigation. We also thank Prof. F. G. Young for his encouragement.

Influence of Deoxyribonucleic Acid Content on the Proteolysis of Sputum and Pus

Deoxyribose nucleoprotein (DNP) has been identified as an important constituent of purulent exudates, constituting 30–70 per cent of the total solids[1]. The action of deoxyribonuclease (DNase) in liquefying such exudates has been largely ascribed to the depolymerization of DNA[2–6]. Sherry, Johnson and Tillett[4] observed that acid-soluble nitrogen was progressively liberated into solution following the addition of DNase to the exudate. Similarly, liberation of trichloroacetic acid (TCA) soluble tyrosine was noted during our investigation of DNase action on purulent sputum. It is possible that this liberation of TCA soluble tyrosine resulted from the digestion of protein by an intrinsic proteolytic enzyme which requires depolymerization of interfering DNA. This communication is concerned with the testing of the hypothesis: (*a*) that a nucleoprotein, resistant to proteolysis, exists in sputum and pus; (*b*) that the protein becomes susceptible to a native proteolytic enzyme after the nucleoprotein complex has been split.

Specimens of purulent sputum were obtained from 10 children with cystic fibrosis and 5 patients with bronchiectasis, and 8 samples of pus were obtained from infected wounds, empyema and abscesses. The material was homogenized in distilled water with a

Potter–Elvehjem homogenizer to form 10 per cent homogenates. Aliquots (3·0 ml.) were mixed with 2·0 ml 0·05 M phosphate buffer, *p*H 7·5, and 0·1 ml. DNase solution (5 mg DNase/ml. 0·1 N acetate buffer, *p*H 4·5), and placed in a 37° C water bath. TCA-soluble tyrosine was assayed at 15-min intervals with the Folin–Ciocolteau reagent[7].

DNase caused a progressive (first order) increase of TCA-soluble tyrosine in all the sputum and pus specimens (Fig. 1). Addition of 10 mg soybean trypsin inhibitor (SBTI) to the reactant mixtures resulted in approximately 50 per cent inhibition of proteolysis during a 1-h incubation period. These results suggested that DNase initiated a proteolytic reaction which could be partially inhibited by SBTI, and therefore probably resulted from the action of a proteolytic enzyme in the exudates.

When 0·5-ml. aliquots of the homogenates were added to 5·0 ml. of 3 per cent casein ('Pfanstiehl') in 0·05 M phosphate buffer at *p*H 7·5, a 0-order reaction curve for casein digestion resulted (Fig. 2). The addition of DNase to this mixture did not significantly affect the rate. It was thus apparent that the specimens of purulent sputum and pus contained a proteolytic enzyme capable of digesting casein, but incapable of digesting the intrinsic protein of the exudate unless preceded by DNase action. Further investigation of this protease revealed it to resemble chymotrypsin in that it had specific esterase activity for the aromatic amino-acid ethyl esters (tyrosine, phenylalanine and tryptophan). The protease was present in the sediment of the exudates and was soluble in 2 M sodium chloride.

An experiment designed to demonstrate that the native protease was necessary for the proteolysis induced by DNase was performed as follows: A portion of sputum homogenate was heated in an 80° C water bath for 1 h. This material no longer split acetyl-L-tyrosine ethyl ester substrate, unlike the unheated sputum homogenate. The sediments from this heated specimen and from an unheated specimen were removed by centrifugation at 16,000 r.p.m. at 0° C for 15 min., and resuspended to their original volumes in distilled water. DNase was added to aliquots of each specimen as described here, incubated at 37° C, and periodically assayed for TCA-soluble tyrosine. No proteolytic activity occurred in the heated specimen, whereas proteolysis occurred in the unheated specimen as in Fig. 1. On the other hand, when protease was then added to the heated specimen in the form of 0·5 ml. of unheated sputum homogenate, TCA-soluble tyrosine was released. These experiments demonstrate that the DNase alone is not responsible for proteolysis, but induces proteolysis only by making substrate available to the protease when the latter is present.

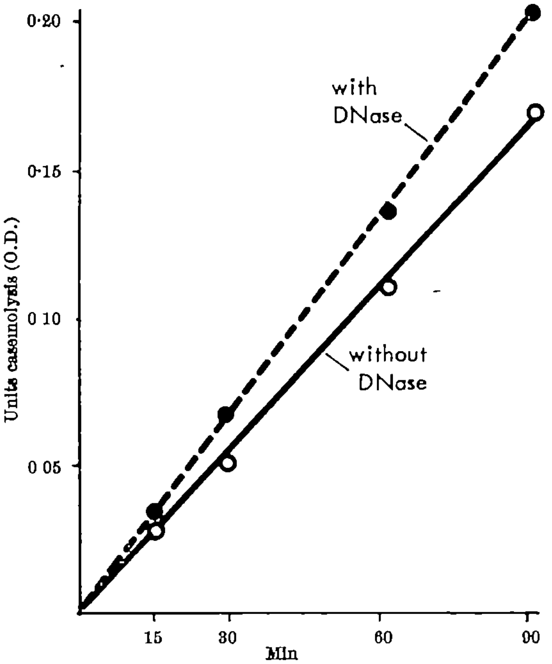

Fig. 2. Caseinolytic activity of protease from purulent sputum and pus; 3 per cent in 0·05 M phosphate buffer, *p*H 7·5

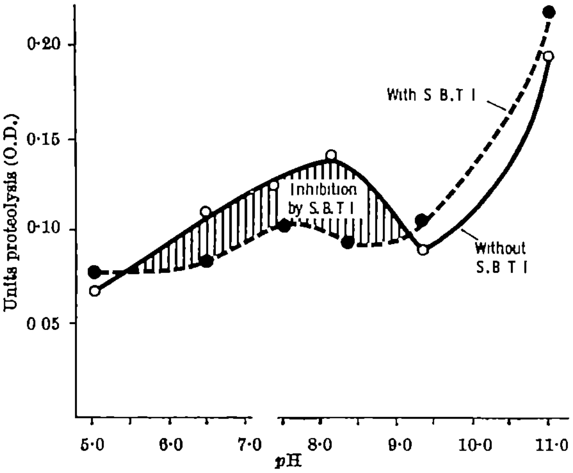

Fig. 3. Optimum *p*H curve for intrinsic proteolysis of purulent sputum resulting from 1·5 M sodium chloride. Shaded area indicates inhibition by soybean-trypsin inhibitor (SBTI)

Further evidence that DNA renders the protein in the complex unavailable to the proteolytic enzyme present in purulent sputum and pus was provided by dissociating the nucleoprotein complex with high concentrations of sodium chloride[8]. Mixing the homogenate with 2 M sodium chloride (1 part homogenate to 2 parts sodium chloride solution) resulted in the same proteolytic activity as occurred with DNase. The effect of *p*H on this phenomenon is shown in Fig. 3. Two peaks of proteolysis are seen: one at *p*H 7·5–8·0, and a second abrupt rise of apparent proteolysis at a more alkaline *p*H around 11·0. The first peak of activity is true enzymatic activity that can be partially inhibited by SBTI as shown in Fig. 3. In addition, this first peak corresponds to the optimum *p*H observed when the protease is tested on a casein substrate. The second peak, however, probably respresents a non-enzymatic hydrolysis.

DNase alone and 2 M sodium chloride alone each produces maximum proteolysis at *p*H 7·5, and there is no additive effect. This suggests that both DNase and concentrated sodium chloride act by dissociating DNA from protein, thereby making protein available for proteolysis.

The chymotrypsin-like enzyme activity of sputum appears to be a function of its purulency; this enzyme was present in all purulent sputa examined, but was absent from non-purulent specimens[9]. A possible bacterial source for the enzyme was ruled out by studying proteolytic activity of bacterial cultures from the specimens. In addition, some of the pus samples were sterile. Mounter and Atiyeh[10] studied the protease activity of buffy coat leucocytes and their description of this activity resembles our observations of the protease in exudates. Although we did not find three peaks of optimum activity at *p*H 3·0, 6·0 and 8·0 as they did, our findings coincide with their description of the enzymatic activity apparent at *p*H 8·0, in so far as its esterase activity and optimum *p*H are concerned. It appears probable that the protease activity of purulent sputum and pus is derived from the leucocytes.

This work shows that the DNA content of purulent sputum and pus acts to prevent enzymatic hydrolysis of protein within the secretions, probably by forming a complex with the potential protein substrate. All purulent specimens examined were found to contain a chymotrypsin-like enzyme that was capable of lysing the exudate protein only following cleavage of the nucleoprotein complex, as by DNase or by 2 M sodium chloride. Thus it appears that the viscosity-lowering action of DNase is at least in part due to the induced enzymatic hydrolysis of protein.

Thermodynamics of Biological Growth

In a recent communication, Stoward[1] presented data on heat production during the growth of *Aerobacter aerogenes* with the view of contributing information on Prigogine's[2] hypothesis that living organisms tend to a state of minimum entropy production. In view of the fundamental importance of this hypothesis, it seems necessary to examine in some detail the results given by Stoward[1].

These results appear to contain a systematic error, as the thermal data do not follow the form of the growth curve of the bacteria, and no inflection occurs in the heat record at the time at which the stationary phase is reached. This is the behaviour to be expected from a measuring system the time constant of which is too long to follow the rapid changes in rate characteristic of an exponential function. The problem of response time is of particular importance in kinetics; Sirs[3] has shown that, to reproduce the form of an exponential without serious distortion, the time constant of the measuring system must be very much less than the half-time of the exponential. We have found glass containers unsuitable in calorimetric kinetic apparatus[4], and Sturtevant's[5] analysis of the problem shows that even metal vessels may introduce lags in some calorimetric measurements of rate processes. The type of error introduced by thermal lag is shown in Figs. 1 and 2. These compare heat production curves obtained during bacterial growth, using (Fig. 1) glass calorimeter vessels which imposed a serious thermal lag and (Fig. 2) thin metal vessels which enabled this lag to be reduced to a very low level. The data are plotted in the integrated form so that the correlation is obvious. If the determinations of bacterial mass are measurements without time error, but a substantial lag occurs in the thermal estimations, then the functions derived from these measurements will be seriously distorted. We suggest that since Stoward[1] used a glass calorimeter vessel, his data are affected by such a time-lag.

We have recently investigated one aspect of the Prigogine hypothesis, that is, the relative heat production of bacterial cells at different parts of the growth curve[6]. Within the limits of precision of our measure-

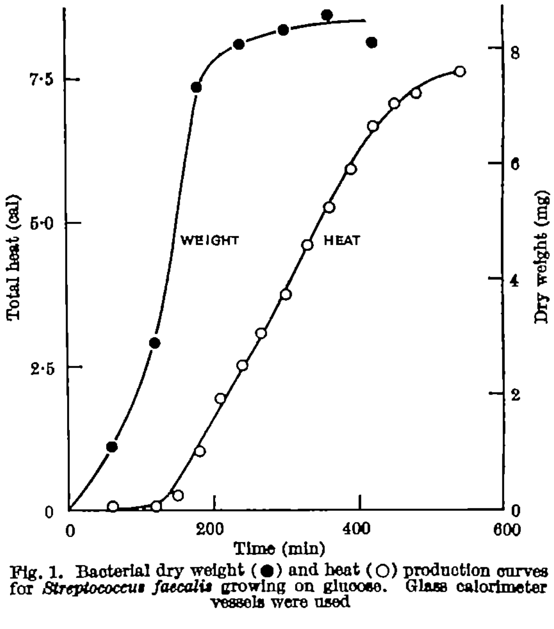

Fig. 1. Bacterial dry weight (●) and heat (○) production curves for *Streptococcus faecalis* growing on glucose. Glass calorimeter vessels were used

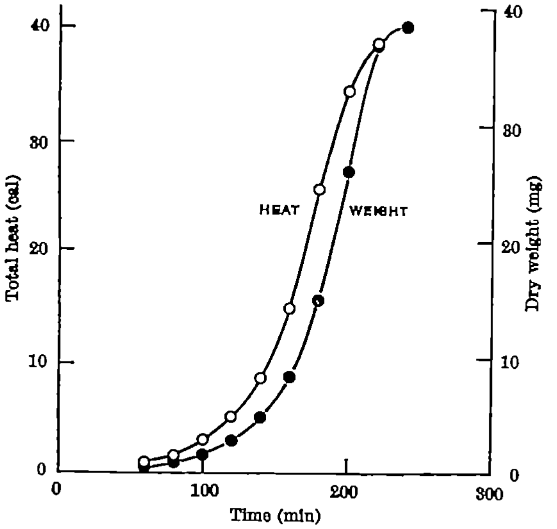

Fig. 2. As in Fig. 1, except that thin aluminium calorimeter vessels were used

ments, it was not possible to demonstrate any significant difference between the heat production of unit bacterial masses at different stages of exponential growth. Heat-changes during the lag phase were too small to allow accurate compilation of data on heat per unit mass, but during the exponential phase the heat evolved per unit mass of bacteria ($\Delta H/M$) against time is constant. On the other hand, the ratio $\Delta H/n$, that is, heat per bacterial cell, shows a tendency to increase during the exponential phase (Fig. 3). This is explicable on the grounds that the average cell size increased during growth. Since, in our experiments, substrate was the factor limiting growth, comparisons with Stoward's[1] data do not extend beyond the exponential part of the growth curve.

The reactions occurring during growth and in the stationary phase are not strictly comparable. During the stationary phase essentially all the substrate present is degraded so that the heat produced can be correlated with thermodynamic data calculated for a simple reaction[6]. However, during growth, synthesis of cell material from the substrate may occur, so that a portion of the substrate is not degraded and ΔH for a simple reaction is no longer applicable.

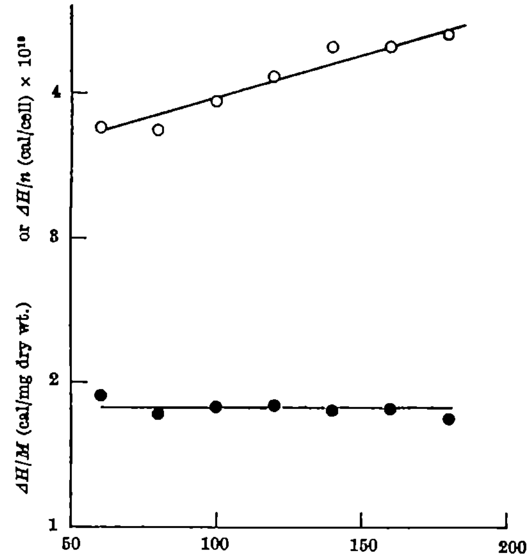

Fig. 3. Heat per cell ($\Delta H/n$) versus time (○) and heat per unit dry weight ($\Delta H/M$) versus time (●). Data used were obtained from the experiment depicted in Fig. 2

We therefore consider that, for the foregoing reasons, the data obtained by Stoward[1] are unsuitable for the determination of the thermodynamic characteristics of living systems.

[6] Forrest, W. W., Walker, D. J., and Hopgood, M. R., *J. Bact.*, 82, 648 (1961).

The criticisms suggested by Forrest and Walker (preceding communication) that thermokinetic data can be distorted by systematic lags in the measuring apparatus are quite valid in general, but they do not apply to a detailed examination of my apparatus[1].

The principal sources of thermal lag in calorimetric measurements arise from the finite response time of the temperature-recording system, and the failure of the temperature of the calorimeter jacket and head to keep in step with the changing temperatures of the reaction media. The effective response time of my temperature-recording system is less than 2 sec when a sensitive galvanometer is used[1], or less than 10 sec when rises in temperature are displayed on a recording potentiometer[1]. These response times will obviously have little effect on derived temperature-time curves when bacterial growth-rates are measured to the nearest 1–2 min.

On the other hand, errors of thermal lag arising from the comparatively high heat capacities and low thermal conductivities of the calorimeter head and jacket materials can be much more serious[3]. Because of the very low thermal conductivity of silicone rubber, my calorimeter head[1] can be regarded as part of the 'isothermal shield', and therefore any temperature lags must occur in the inner calorimeter vessel itself.

The temperature of the outer wall of the inner (glass) vessel (θ_2) at time t is related to that of the fluid medium (θ_1) by the equation[2]:

$$\theta_2=\theta_1 + (4c_1-2Bc_2)/B^2 - (4c_1/B)t + (2Bc_2-4c_1)/B_2\cdot \exp(-Bt) \quad (1)$$

when θ_1 follows a rate of the form[2]:

$$d\theta_1/dt=c_1t+c_2 \quad (2)$$

where c_1 and c_2 are constants.

The constant $B=4\pi\kappa rl/C_px$, where κ is the thermal conductivity, r the radius, l the length, C_p the heat capacity and x the wall thickness of the inner calorimeter respectively. Putting $\kappa=0{\cdot}002 \times 3{\cdot}6 \times 10^3$ cal. cm^{-1} deg^{-1} h^{-1}, $r=1$ cm, $l=10$ cm, $C_p=4$ cal. deg^{-1}, and $x=0{\cdot}05$ cm, then $B\sim 4\times 10^3$.

Owing to a transcript error the values of $\overline{\Delta H}$ and $\overline{\Delta h}$ in ref. 1 were inadvertently divided by 10. When the correct values of $c_1=0{\cdot}01$ and $c_2=0{\cdot}05$ for *A. aerogenes* growing in a synthetic glucose medium[1] are substituted, the last term in equation (1) is negligibly

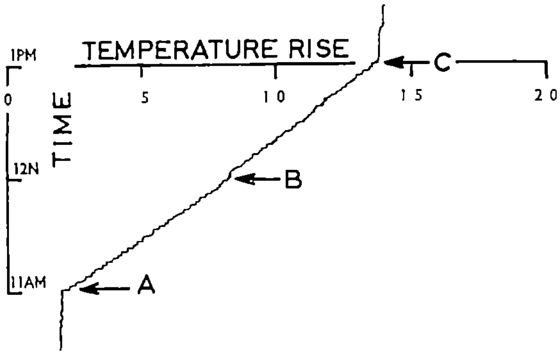

Fig. 1. A typical calibration curve for an adiabatic microcalorimeter. The figure 1·0 on the temperature scale is roughly equivalent to 0·25° C. The constant temperature for the 0·5-h periods before (*A*) and after (*C*) passing the current should be noted

small, while the second and third terms are $\sim -10^{-5}$ after 4 h, which are still very much smaller than the smallest measurable temperature increment (0·005°). Similar numerical results can be obtained if other time functions are substituted for equation (2). This means that $\theta_1 = \theta_2$ within the limits of experimental error.

These theoretical conclusions for the absence of thermal lag have been verified many times in calibration experiments in which a known amount of electrical energy is passed into the calorimeter. No further rise in temperature was observed when the current was switched off in the isothermal calorimeter[1], and a cooling curve can always be plotted immediately. Unfortunately no experimental tracings exist to prove this point, but when the same calorimeter assembly was modified to an adiabatic type[2], calibrations curves such as shown in Fig. 1 are obtained. If thermal lag exists in the calorimeter it will be manifested in further rises in temperature in both the isothermal and adiabatic models when the current is switched off. Fig. 1 shows that the thermal lag is practically zero at all times except possibly for a short period ($\sim$ 2 min) at point *B*, which is probably due to temporary inadequate stirring.

For twin calorimeters as used by Forrest[4], however, it is necessary to construct both vessels from materials of the highest thermal conductivity: this arises from the practical necessity of having two calorimeters of the same thermal leakage. Experiments carried out here confirm Forrest's experience in finding glass vessels unsuitable for this type of calorimeter. Moreover, Forrest and Walker (preceding communication) have not demonstrated unequivocally that glass vessels introduce a thermal lag; a comparison of the numerical results plotted in their Figs. 1 and 2 indicate that their experiments were not carried out under comparable conditions, although their text and the legend of their diagrams intimate that they were.

The most likely interpretation of the different results obtained by Forrest *et al.*[5] and myself lies in the different growth conditions. In my experiments, *A. aerogenes* probably changes its metabolic activity during growth, particularly in the so-called stationary phase. The increasing high growth temperature may also result in the uncoupling of some energy-yielding reactions[6]. The best way of resolving the differences and afterwards testing Prigogine's[7] hypothesis for individual organisms is to carry out simultaneous heat production and Gibbs energy change measurements in synchronously growing cultures under conditions in which the metabolic pathways are strictly controlled.

I thank Drs. R. Barer and L. A. K. Staveley for encouraging discussions, and the Department of Scientific and Industrial Research for past and present financial support.

Phytylation of Chlorophyllide and the Formation of Lamellæ in Chloroplasts

ONE of the earliest recognizable changes in plastid fine structure after exposure of etiolated leaves to high light intensity is the disappearance of the vesicular centre (prolamellar body) and formation of concentric layers of vesicles[1,2]. A similar structural change was reported for plastids of etiolated leaves after illumination for 24 h with fluorescent light of 400 ft.-candles at 3° C (ref. 3), or after illumination with 2 ft.-candles at 26° C (ref. 4). All these conditions allow photoconversion of those chlorophyll precursors existing in the etiolated leaves, but are unfavourable to chlorophyll accumulation[4]. It has been suggested that the grouping of vesicles into 'ring structures' in plastids is connected with low chlorophyll content[1,4,5].

Etiolated bean leaves contain mainly protochlorophyllide, which is converted to chlorophyllide on exposure of the leaves to light, and is afterwards phytylated to chlorophyll[6]. It has also been proposed that phytylation may be a factor in formation of lamellæ in plastids[7]. Since the organization of vesicles into concentric layers under the influence of light is a very early step in formation of lamellæ, we investigated whether the chlorophyll exists in the phytylated or non-phytylated form in plastids containing these 'ring structures'.

Leaves were detached from 12–14 day old etiolated bean plants and floated on water for 24 h at 26° C under white fluorescent light of 2–5 ft.-candles. This treatment produces plastids with vesicles arranged in concentric layers[4]. Leaves were also floated in complete darkness, under which conditions the vesicular centres remain unchanged in the plastids, and under light of 400 ft.-candles, when a normal lamellar system develops. After immersion of the leaves in boiling water the pigments were extracted quantitatively from leaf samples with acetone, each extract divided into aliquots, from one of which the phytylated pigments were removed by petroleum-ether, as described by Holden[8]. The absorption curves of the extracts of leaves kept in darkness showed the presence of protochlorophyll(ide), while extracts of leaves illuminated with 2 or 400 ft.-candles gave absorption spectra of chlorophyll(ide). In Table 1 the optical density of the petroleum–ether-treated acetone

Table 1. PERCENTAGE OF LEAF PIGMENTS NON-TRASFERABLE FROM 50 PER CENT ACETONE TO PETROLEUM–ETHER

Treatment	100 × optical density ratio*	
Leaves floated in darkness	72 ± 3·6†	(measured at 630 mμ)
Leaves floated under light of 2–5 ft.-c.	73 ± 1·8	(measured at 665 mμ)
Leaves floated under light of 400 ft.-c.	20 ± 3·6	(measured at 665 mμ)

$$* \; 100 \times \frac{\text{Optical density of petroleum–ether-treated acetone extract}}{\text{Optical density of untreated acetone extract}}$$

† *S.E.*

extracts is given as a percentage of optical density of the respective untreated acetone extracts.

Taking these data as an indication of the relative amount of non-phytylated pigments present in the leaves[6,8], it can be noted that in leaves kept in darkness, where the plastids have vesicles arranged in vesicular centres, the main part of the pigments consists of protochlorophyllide. It is also evident that no phytylation occurred after 24-h exposure of the leaves to low light, which thus contained chlorophyllide. Here, as aforementioned, the plastids still show vesicles, although now arranged in concentric layers. Among the variously treated leaves, phytylated chlorophyll occurred only in those which were exposed to 400 ft.-candles, and which have plastids with normal lamellar systems.

These results show that the rearrangement of vesicles from the vesicular centres into concentric layers—which is considered to be a photo-dependent process[1]—may be connected with the photo-conversion of protochlorophyllide to chlorophyllide but not with its change to chlorophyll, and indicate that the inability of the vesicles to fuse to lamellar structures under those conditions may be due to lack of phytylated chlorophyll. The same may be true for the formation of identical ring structures under high light intensity but low temperature[3], since Wolff and Price have shown that phytylation does not occur at 0° C (ref. 6). The results thus tend to confirm the suggestion of Butler[7] that phytylation may be a necessary factor in fusion of vesicles to lamellar structures.

Carnitine as a Fatty Acid Carrier in Intermediary Metabolism

CARNITINE has been shown to stimulate the oxidation of long chain fatty acids by cell particle preparations[1]. The mechanism of this effect has remained obscure.

Friedman and Fraenkel[2] have reported that carnitine is acetylated by a soluble extract of liver in the presence of coenzyme A, adenosine triphosphate and acetate. They also obtained results indicating that the acetyl transfer from acetyl-coenzyme A to carnitine is reversible.

Recently I published results showing that isolated mitochondria from several tissues of the rat have the ability to deacetylate acetylcarnitine. This deacetylation is paralleled by an oxygen uptake correspondding to a complete oxidation of the acetyl group to carbon dioxide and water. Pyruvate apparently prevented the deacetylation of acetylcarnitine. It was also found that, in the presence of pyruvate, free carnitine was acetylated by mitochondria[3].

On the basis of these results it was suggested that carnitine functions as a carrier of active acetate between compartments within the cell[3].

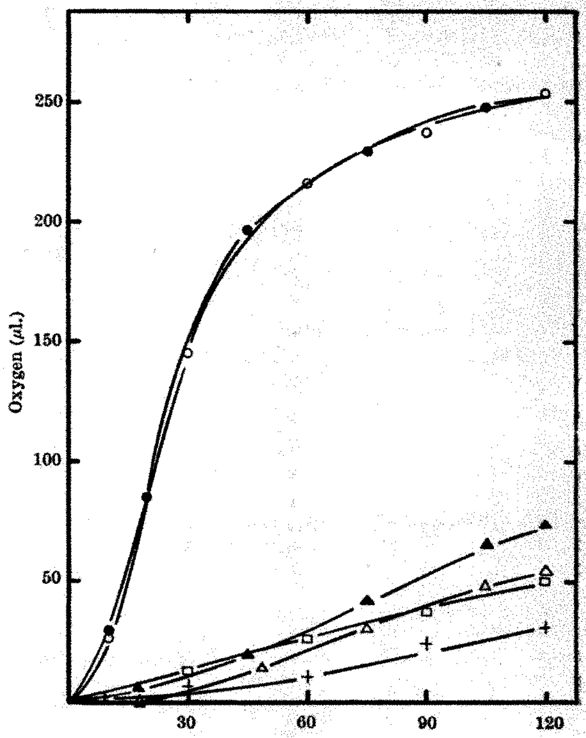

Fig. 1. Effect of DL-carnitine, palmitate and of DL-palmitylcarnitine on the oxygen uptake by rat heart mitochondria. Mitochondria isolated from one rat heart (approximately 1 g), as previously described (ref. 3), were suspended in 6-ml. of 10 per cent sucrose containing 10^{-4} M ethylenediamine tetraacetate. Each Warburg vessel contained in a total volume of 3 ml.: potassium phosphate buffer, *p*H 7·4, 40 µmoles; potassium chloride, 180 µmoles; magnesium chloride, 20 µmoles; AMP, 10 µmoles; succinate, 2 µmoles; crystalline bovine albumin, 30 mg; sucrose suspension of mitochondria, 1 ml. DL-carnitine, palmitate and DL-palmitylcarnitine were added as follows: ○, palmitylcarnitine, 1 µmole; ●, palmitylcarnitine, 1 µmole; +, carnitine, 1 µmole; Δ, palmitate, 1 µmole; ▲, palmitate plus carnitine, 1 µmole of each; □, no addition. The incubation was performed at 30° with air as the atmosphere

As carnitine is most efficient in stimulating the oxidation of long chain fatty acids[1], it may be assumed that carnitine is active as a general acyl carrier in the intracellular transport of fatty acids. To test this hypothesis, I have synthesized palmitylcarnitine and other acyl carnitines and tested these compounds as substrates for isolated mitochondria. Fig. 1 shows that palmitylcarnitine has a strong enhancing effect on the oxygen uptake by heart mitochondria in the presence of catalytic amounts of succinate. Carnitine or palmitate added individually showed no enhancing effect, while the combination palmitate plus carnitine showed a small stimulatory effect in agreement with the observations of Fritz *et al.*[1]. The far more pronounced effect of palmitylcarnitine strongly suggests that this compound is an intermediate in the carnitine stimulated oxidation of palmitate. Similar results were obtained with butyryl—and with octanoylcarnitine.

Previously we have shown that only L-acetyl carnitine is metabolized by mitochondria[3]. The synthetic palmitylcarnitine used in the experiment shown in Fig. 1 is the racemic DL-compound. The net oxygen uptake obtained in the experiment shown corresponds to 40–45 per cent of the uptake expected if all the bound palmitate added had been oxidized. This indicates that only one optical isomer, presumably the L-form, is metabolized.

Thus, palmitylcarnitine seems to represent a water-soluble, activated fatty acid metabolized by mitochondria. The enzymatic synthesis of this compound remains to be demonstrated. If carnitine, as suggested, functions as a carrier of activated fatty acids across the mitochondrial membrane for utilization in the citric acid cycle, an extramitochondrial localization of the carnitine acylating system should be expected.

Polyphenolic Derivatives in Rhabdomeres of the Compound Eye

THE chemical composition of a homogenized compound eye was reported by Langer[1], but until now nothing was known about the components of rhabdomeres alone, although the presence of photosensitive substances in rhabdomeres has been anticipated by many investigators from a long time ago. During the course of histochemical studies on the compound eye of a house fly, *Musca vicina* Macquart, periodic acid–Schiff-positive substances were found to be distributed in rhabdomeres of a dark-adapted eye. The periodic acid–Schiff reaction of rhabdomeres was always positive both in a dark-adapted eye treated with saliva for 1 h in an incubator and in a light-adapted eye (Fig. 1). In addition to this, Bauer's reaction of rhabdomeres was very weak.

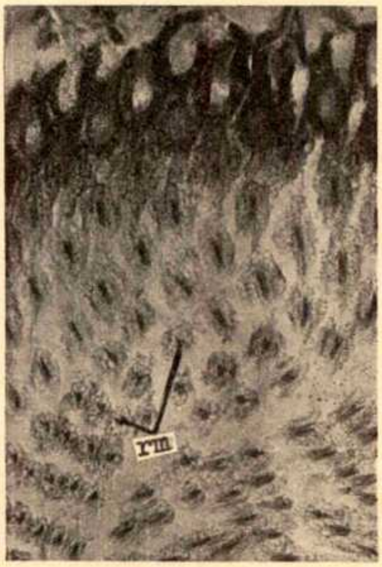

Fig. 1. Cross-section of a light-adapted eye. Periodic acid–Schiff reaction is still evident in the rhabdomeres (*rm*)

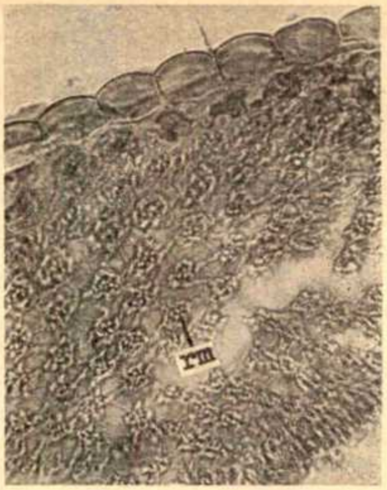

Fig. 2. Chromaffin reaction in a dark-adapted eye (cross-section)

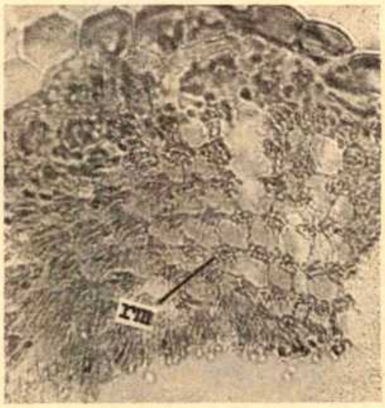

Fig. 3. Chromaffin reaction in a light-adapted eye (cross-section)

From these results, it was considered that most of the substances in the rhabdomeres are not polysaccharides. According to Lison[2], the substances showing a positive periodic acid–Schiff and a negative Bauer's reaction are regarded as proteins or other elements different from polysaccharides. In my investigations, the fly's rhabdomeres were proved to be positive for Millon's reaction, potassium iodate, potassium bichromate and ammoniacal silver, but negative for both the detections of α-amino radical with a ninhydrin and indole radical with a syrupy phospholic acid. In general, the positive Millon's reaction is considered to indicate the existence of tryptophan, tyrosine and other phenolic compounds; but from the negative reaction for both indole and α-amino radicals, it may be suggested that the rhabdomeres of *Musca* do not contain α-amino-acids such as tryptophan and tyrosine. Therefore, in the present circumstances, the positive Millon's reaction of the rhabdomeres may be regarded as proof of the presence of phenolic derivatives. These reactions become more indistinct in a light-adapted eye than in a dark-adapted eye (Figs. 2 and 3).

Identification of the Origin of Animal Protein by Agar-gel Diffusion

The identification of the origin of various animal proteins proved possible by the agar-gel double diffusion technique[1]. Antisera were prepared in rabbits by multiple injections of alum-precipitated animal sera. Antigens were prepared from animal sera and tissue extracts, tick blood-meals, sun-dried meat or biltong and uncooked sausage meat. They were diffused overnight at 25° C against known antisera simultaneously with the homologous antigen. The agar gels were prepared from 1 per cent agar in borate buffer at pH 8·6 and were about 3 mm thick. A seven-well pattern was used consisting of a 9·5-mm diameter central well set 10 mm from the 7-mm diameter peripheral antigen wells.

Precipitation occurred, and the degree of precipitation appeared to be correlated to the zoological family of the animal of origin. For example, pig and horse sera used as antigens reacted with buffalo antiserum, but the precipitation bands were not as prominent as that which formed with sheep serum used as an antigen (Fig. 1). Within a sub-family, spur formation distinguished different genera (Fig. 2).

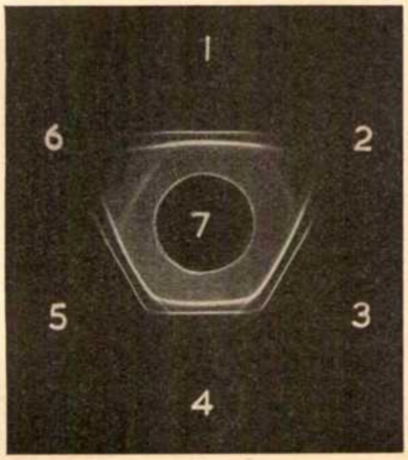

Fig. 1. Wells 1, 3 and 5 contain buffalo antigen; 2, horse antigen; 4, sheep antigen; 6, pig antigen; 7, unabsorbed rabbit anti-buffalo serum

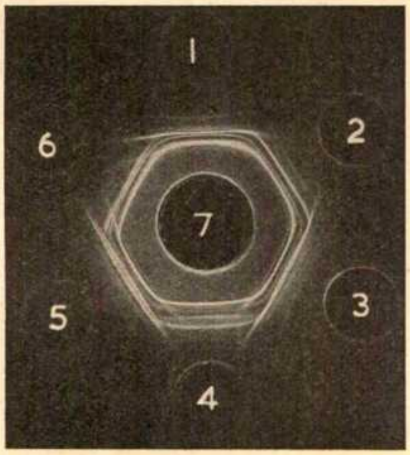

Fig. 2. Wells 1, 3 and 5 contain ox antigen; 2, buffalo antigen; 4, wildebeest antigen; 6, eland antigen; 7, unabsorbed rabbit anti-ox serum

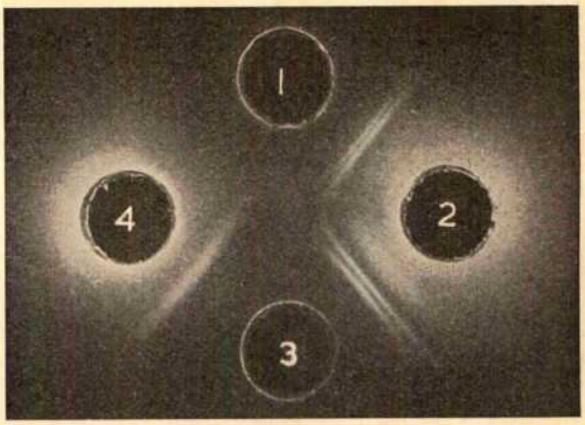

Fig. 3. Well 1 contains horse antigen; 2, unabsorbed rabbit anti-zebra serum; 3, zebra antigen; 4, absorbed rabbit anti-zebra serum

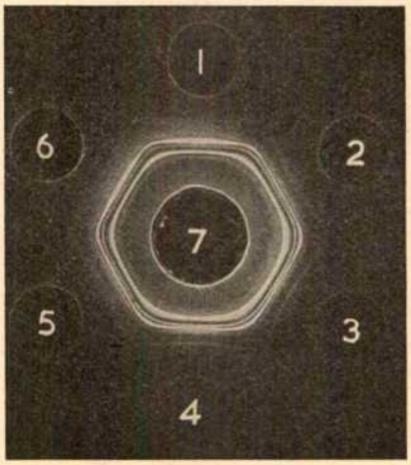

Fig. 4. The peripheral wells contain antigen from six different cattle. The centre well contains rabbit anti-ox serum

The identification of species within a genus was possible when absorbed antiserum was used. For example, an antiserum to zebra antigen reacted with both zebra and horse antigens but when absorbed with horse antigen it reacted only with zebra antigen and not with horse antigen (Fig. 3). Antigens in the form of sera from individual animals of the same species did not form spurs (Fig. 4).

PHYSIOLOGY

Binding of Calcium Ion to Lecithin Film

The calcium ions in the membrane appear to be involved in some way with the unknown physicochemical reactions which occur in the membrane and which may be responsible for the changes in the membrane permeability or the membrane potential of excitable tissues[1,2]. Inasmuch as the membrane is composed of lipoproteins which possess negative phosphoric sites of phospholipids, it is likely that the calcium ions are bound to these sites. The experiment recorded here, therefore, was projected to determine whether or not calcium ions could actually bind to phospholipids, and if so, whether the binding of calcium ions would be affected by monovalent cations or other substances.

The radiotracer method using a soft β-emitter has proved very successful for the direct measurement of adsorption at the solution-air interface[3]. This technique was applied to study the adsorption of calcium ions (calcium-45) to a lecithin monolayer. The radioactive solution was introduced in a paraffin-coated planchet, and the radiation from the surface was counted by means of a Geiger–Müller counter before and after the spreading of the monolayer film. The radioactive solution (about 20 mc./mM) contained 2·4 sodium bicarbonate (*p*H, 8·2 ± 0·1) except in cases for the study on *p*H. Caution was taken so that counting was done under a constant geometrical condition throughout. L-α-(β,γ-dipalmitoyl)-lecithin (PL) and animal lecithin (AL) were used for the monolayer films. The former was chromatographically homogeneous whereas the latter (shown by Dr. L. G. Abood, of this laboratory) consisted of three kinds of lecithin with a purity of more than 90 per cent. Stearic acid was also used. The spreading solution, prepared by dissolving a material either in petroleum ether or in petroleum ether containing 2 per cent propanol, was carefully spread on the whole surface of the radioactive solution to obtain a uniform surface film.

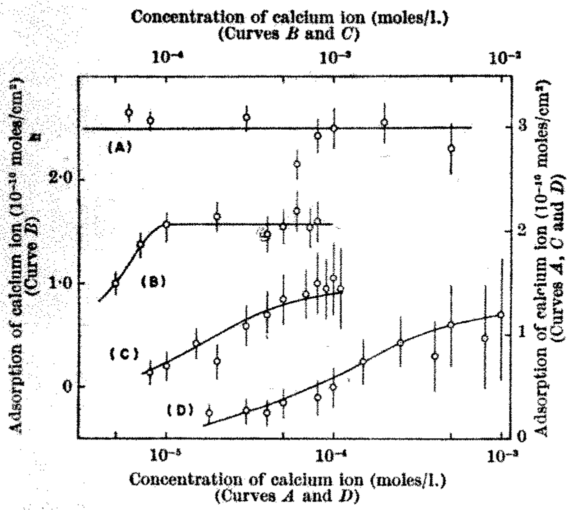

Fig. 1. Adsorption of calcium ions to surface films. Curve *A* represents adsorption isotherm for monolayer of stearic acid (surface concentration: $6{\cdot}0 \times 10^{-10}$ moles/cm²); curve *B* for *AL* film (surface concentration: 24 mg/m²); curve *C* for *PL* film (surface concentration: $24{\cdot}5 \times 10^{-10}$ moles/cm²) and curve *D* for monolayer of *PL* (surface concentration: $2{\cdot}45 \times 10^{-10}$ moles/cm²)

Fig. 1 shows the adsorption isotherms for the given surface concentrations of the lecithin films as well as of the stearic acid monolayer. The adsorption of calcium ions to the stearic acid monolayer is in saturation over the concentrations studied. The saturation value shows the formation of calcium distearate. Similarly, the binding ratio of calcium ion to PL is approximately 1/2. Curve *D* represents the relation calculated from the adsorption isotherm:

$$\frac{\varphi}{(1-\varphi)^2} = KC \qquad (1)$$

where φ denotes a half a fraction of saturation, and *C* and *K* the concentration of calcium ion and the constant, respectively. The value of *K* was $3{\cdot}4_7 \times 10^3$ mole^{-1}. The adsorption isotherm indicates that the surface film is an athermal mixture of lecithin and calcium salt of lecithin, with an occupied area twice as large as the uncombined lecithin.

The adsorption of calcium ions to the multimolecular film (Curve *C*) can be expressed by the isotherm identical with that for the monomolecular film. The saturation value agrees well with that expected for a closely packed lecithin monolayer, provided the occupied area is about 40 Å² per molecule. These findings indicate that only the layer facing the aqueous phase is capable of taking up calcium ions. A similar presumption is applicable to the adsorption of calcium ions to the animal lecithin film.

The effect of foreign substances on the adsorption of calcium ion to animal lecithin was studied with solutions containing 0·1 mM calcium chloride and foreign substances. Results are shown in Table 1. The decrease in the adsorption of calcium ions would be either due to the competition between calcium and monovalent cations, or to the chelating action of the foreign substance.

Table 1. EFFECT OF FOREIGN SUBSTANCES ON THE ADSORPTION OF CALCIUM ION TO ANIMAL LECITHIN*

Foreign substances	Concentration	Fraction of adsorption of calcium ion
No foreign substance	—	1·0
ATP	0·3 mM	0
EDTA	0·4 mM	0
Acetylcholine chloride	5 mM	1·0
KCl	112 mM	0·51
NaCl	112 mM	0·5
H^+	10^{-7} M (*p*H = 7)	0·9
H^+	$10^{-5{\cdot}3}$ M (*p*H = 5·3)	0·5†

* Concentration of calcium ions in solution was 0·1 mM.
† Sodium bicarbonate was not added.

These experiments demonstrate that calcium ions are capable of binding to the monolayer film of lecithin within a physiological range of *p*H. On the basis of this finding, we may conclude that calcium ions are bound to phospholipids present in the membrane of living excitable cells. Results suggest that calcium ions may be binding with two negative oxygen sites and forming a bridge between two radically oriented phospholipids[1]. It is of interest that the binding of calcium ions to the lecithin monolayer is saturated at a relatively small concentration which corresponds to the minimum calcium concentration necessary to maintain the physiological function of living excitable cells. Furthermore, the present investigations indicate that monovalent cations, such as sodium and potassium ions, are in competition with calcium ions. A similar competition probably exists in the case of the living cell membrane[1,2]. The fact that adenosine triphosphate (ATP) hinders the adsorption of calcium ions to the lecithin may provide a key for understanding the actual role of the ATP located in the membrane or its vicinity[4].

Neuromuscular Fatigue in Dystrophic Muscle

THE effects of the dystrophic process upon muscle function are of continued interest. Dystrophic mouse muscle has been found to exhibit multiple action potentials, spontaneously, as well as in response to a single stimulus to its nerve[1,2]; *d*-tubocurarine or sustained, periodic single shock stimulation shortens the after-discharges[1]. Heightened muscle responsiveness and excitability to dual shocks also develop[1]. In addition, excised dystrophic muscle is less fatiguable and maintains a tetanus for a longer time than the normal[3]. It was felt that an investigation of neuromuscular fatigue might help to further delineate and perhaps clarify some of these phenomena.

Twenty-six experiments were performed on 11 dystrophic mice (strain 129, *dy dy*, Jackson Memorial Laboratory) and 15 normal litter-mate controls. An *in situ*, *in vivo* technique of nerve-muscle preparation was used, with intact circulation to the limb, after general anæsthesia with amobarbital sodium. Isometric muscle tension measurements were made from exposed gastrocnemius muscle stimulated directly or through the sciatic nerve. Fine steel and silver macro-electrodes were used for stimulation and recording. Both tension (through a mechano-electronic transducer tube) and action potentials were displayed on a dual beam oscilloscope and recorded by continuous strip camera.

The results of single shock stimulation through the nerve are shown in Fig. 1*A*. In the control muscle, a single action potential occurs, along with a typical twitch tension response. The response in the dystrophic is characterized by a multitude of asynchronous potentials and a tension record of longer duration than the control, although much less actual tension is developed. This appears to be a brief tetanus response to a single stimulus. Tetanic stimuli, at 100 per second applied through the nerve, also resulted in a more prolonged maintenance of both the tension response and action potential activity in the dystrophic (Fig. 1 *B*).

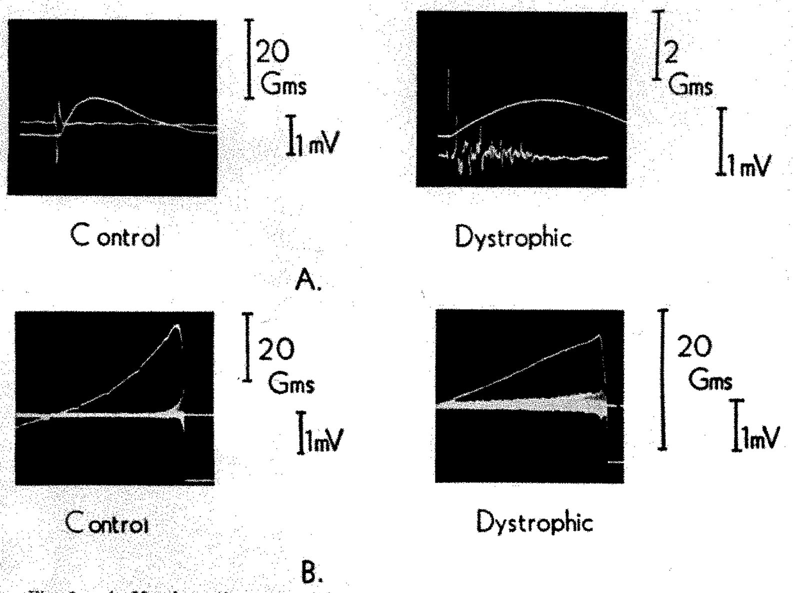

Fig. 1. *A*, Muscle action potential and tension response to single stimulus through nerve; *B*, muscle action potential and tension response to tetanic stimuli through nerve at 100 per sec

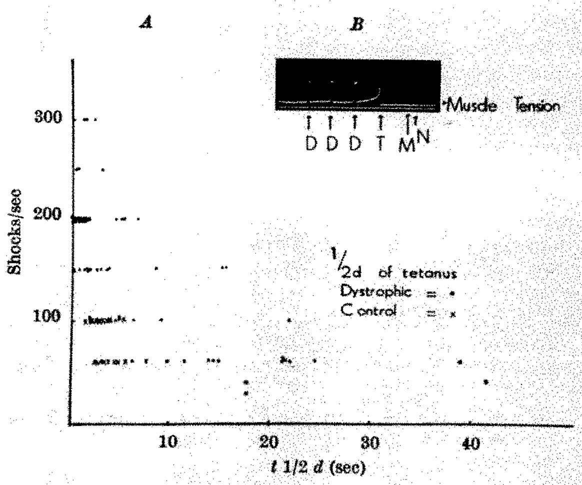

Fig. 2. *A*, One-half time decay of tension developed at varying frequencies of tetanic stimulation through nerve to normal and dystrophic muscles. *B*, Tension recording in single experiment with dystrophic muscle. *N*, single stimulus to nerve; *M*, single stimulus to muscle; *T*, tetanic stimuli through nerve at 100 per sec.; *D*, direct muscle stimulation, at 60 per sec for 1 sec, during neuromuscular tetanic fatigue. Time-base at 5-sec intervals

These results led to a study of the fatiguability of neuromuscular transmission. The method utilized tetanic stimuli, at frequencies varying from 10 to 300 per sec, first applied through the nerve, and then, as fatigue developed, periodically directly to the muscle, usually at a constant frequency of 60 per sec. The tension developed by nerve stimulation declined more rapidly at higher frequencies than at lower, in both the control and dystrophic. Measurements of the one-half time decay of the tension curves indicated that the decrease in tension with frequency was more slowly developed in the dystrophic than in the control (Fig. 2*A*). When this decrease had occurred, for example, at a stimulation-rate of 100 per sec, direct muscle stimulation (at 60 per sec) indicated that the muscle itself was still responsive and capable of maintaining a full tetanus (Fig. 2*B*).

It is considered that the method used in this investigation is a valid test of neuromuscular transmission fatigue[4]. This fatigue occurs in dystrophic muscle at a slower rate than normal, along with maintained muscular responsiveness. The phenomenon has a resemblance to 'myotonia' and may be a general property of dystrophic muscle[1,2], varying in degree in accordance with different types of dystrophic process. The evidence is suggestive of an enhancement of transmission through the neuromuscular junction in the dystrophic as compared to normal. This effect could be related to increased muscle responsiveness or excitability[1,3]. However, since it has been found in the present investigation that direct muscle responsiveness is maintained at a point when neuromuscular responsiveness has declined, the implication exists that an additional factor may be an alteration in neuromuscular transmission independent of any primary muscular dysfunction.

Both electrophysiological and actual morphological evidence is accumulating[1,5-7] of changes at the myoneural junction and terminal innervation in dystrophic muscle.

Potassium Excretion during Adrenal Insufficiency

IT was first noticed by Harrison and Darrow[1] that in adrenal insufficiency in dogs the renal tubular function of preserving sodium and excreting potassium was disturbed. This was afterwards interpreted generally as the result of insufficiency of the sodium–potassium exchange mechanism, which was advocated by Berliner *et al.*[2] originally for the explanation of the high output of potassium under a special condition of extremely high potassium load. That the abnormality of excretion of potassium in adrenal insufficiency, except in the final stage, was not dependent upon changes in the glomerular filtration rate has been stressed by Harrison and Darrow[1]. However, their experiments were done under special conditions by giving potassium chloride (10 g) to the intact dog or the adrenalectomized dog treated with cortical extract in order to compare their concentration ratio (urine/plasma ratio) of potassium with that of the untreated adrenalectomized dog at the same high serum potassium-level found in the latter. The ratio obtained in the former reached 40–75, whereas that found in the latter was about 10. In our experiences the former values seem to be abnormally high, perhaps due to adaptation to potassium load[2] to which no attention was paid, while the latter lies rather in the normal range. On the other hand, Harrop *et al.*[3] and recently Fukuda and Koyama[4] have noticed that the rise of concentration of potassium in the plasma in adrenal insufficiency paralleled that of urea or non-protein nitrogen and suggested the possibility that the disturbance in excretion of potassium might be the result of reduced glomerular filtration rate. Therefore, experiments were performed to find out whether the clearance of potassium shows direct relation to the glomerular filtration rate in adrenal insufficiency in dogs. The results were compared with those obtained from intact dogs and adrenalectomized dogs maintained with cortisone (1 mg/kg per day) when the glomerular filtration rate was changed by altering the intake of sodium chloride (0–2·0 g/kg per day).

The clearance of potassium and endogenous creatinine[5] was determined on daily urine with the midday blood sample. Together with these the urinary sodium/chlorine ratio was also measured which can be regarded as a delicate index of sodium bicarbonate reabsorption[4]. The results are presented in Fig. 1. In intact dogs the sodium/chlorine ratio tended to decrease below 1·0 when the glomerular filtration rate was reduced beyond a certain limit. The clearance of potassium was found to be almost in a linear relation to the glomerular filtration rate and decreased when the latter was reduced. In adrenalectomized dogs the relation of sodium/chlorine ratio to glomerular filtration rate was quite contrary to that of the intact animal. The sodium/chlorine ratio increased above 1·0 with reduction of the glomerular filtration rate, until actual sodium bicarbonate loss occurred with alkalization of the urine. The same tendency could be observed in cortisone maintained adrenalectomized animals although the reduction of glomerular filtration rate did not proceed so far, as was found in untreated animals. On the other hand, the relation of clearance of potassium to glomerular filtration rate in cortisone-maintained dogs was almost the same with that of the intact animal (Fig. 1, line *A*), while somewhat elevated clearance of potassium in relation to glomerular filtration rate was observed in untreated adrenalectomized dogs (Fig. 1, line *B*). In any event there could be found no default in the potassium-excreting mechanism in the absence of mineral corticoids when the changes of the glomerular filtration rate were taken into consideration. Rather enhanced clearance of potassium in adrenal insufficiency might be due to the adaptation phenomena to the retention of potassium.

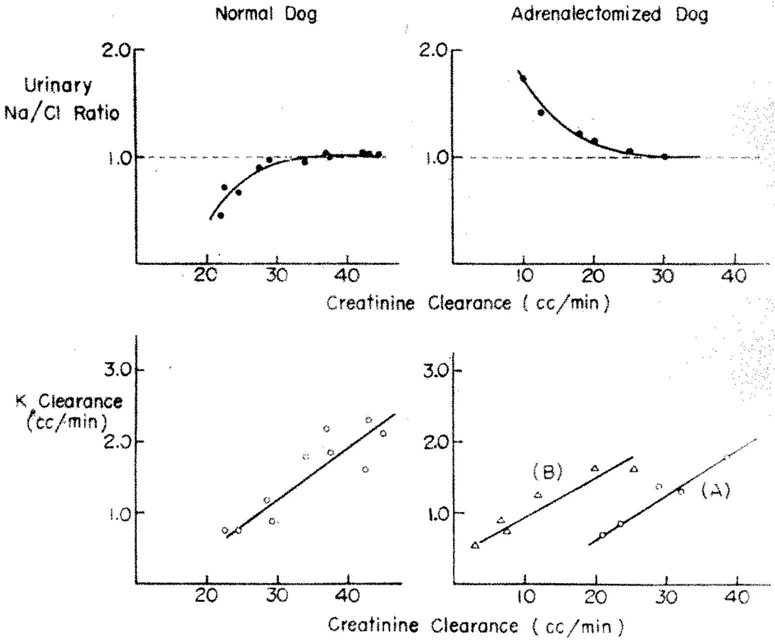

Fig. 1. Relation of the urinary sodium/chlorine ratio and potassium clearance to the glomerular filtration rate. The representative data are taken from three experiments showing similar results. *A*, On adrenalectomized dog maintained with cortisone; *B*, in adrenalectomized dog during the course of adrenal insufficiency

Thus it may be concluded that the main default in the renal handling of electrolytes in adrenal insufficiency in dog was the failure of preserving sodium and especially bicarbonate and that the failure of potassium excretion was merely the result of reduced glomerular filtration rate. That the latter was due to acapnic central deteriorations during the progress of respiratory compensation for the renal acidosis resulting from the excess loss of sodium over chlorine has been fully discussed in a previous report[4]. Glucocorticoids, which can ameliorate this central acapnic deterioration, could prevent the progressive reduction of glomerular filtration rate, as aforementioned (compare the lower limit of glomerular filtration rate in lines *A* and *B* in Fig. 1). Concerning the various kinds of acute experiments showing a short-lived excretion of potassium independent of glomerular filtration rate, care should be taken for leakage of potassium from cells into the tubular urine.

Peripheral Vascular Effects of Mixtures of Isopropylnoradrenaline and Noradrenaline in Man

IT is well known that the infusion of 0·1–1·0 μg/min adrenaline into the brachial artery in man results in an immediate transient increase in flow of blood in the forearm followed by a fall to below the resting level. Allen, Barcroft and Edholm[1] showed that this biphasic response was not due to dilatation of muscle vessels followed by constriction of skin vessels. Finding that after dibenyline, adrenaline produces only a sustained vasodilatation, Ginsburg and Cobbold[2] suggested that the action of adrenaline when given alone was due to an initial stimulation of inhibitory (β) receptors followed by stronger stimulation of excitatory (α) receptors. The action of adrenaline after dibenyline resembles that of isopropylnoradrenaline. Recently we have found that after dichloroisopropylnoradrenaline, adrenaline causes only sustained vasoconstriction, and under these conditions resembles noradrenaline[3].

If adrenaline stimulates first the inhibitory and then the excitatory receptors, we might expect its action to be matched by a suitable mixture of isopropylnoradrenaline and noradrenaline. We have tested this in a series of experiments, of which Fig. 1 shows a typical example. Forearm blood flow was measured by venous occlusion plethysmography. The typical responses to isopropylnoradrenaline (0·05 μg/min) and to noradrenaline (0·25 μg/min) are shown in the first two panels. When these doses of the two drugs were administered simultaneously (panel 3) the response was an initial vasodilatation followed by a vasoconstriction. This response can be seen to bear a strong resemblance to the response to 0·25 μg/min adrenaline, illustrated in panel 4.

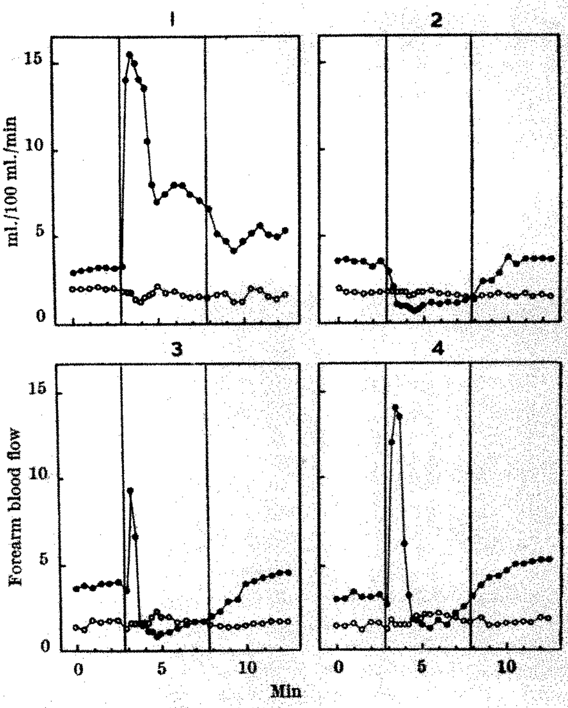

Fig. 1

These results indicate that the response of blood vessels of the forearm to adrenaline can be explained on the basis of the response of the two types of receptor proposed by Ahlquist[4], and thus provide positive evidence for the theory proposed by Ginsburg and Cobbold.

It would be interesting to know if other actions of adrenaline in man and animals can be reproduced by mixtures of isopropylnoradrenaline and noradrenaline, and whether the proportions needed are always the same.

Receptive Fields of Single Cells in the Rabbit Lateral Geniculate Body

THE activity of single cells in the lateral geniculate body of lightly urethanized rabbits has been recorded with steel micro-electrodes[1]. The retinal receptive fields of these cells have been explored. The light source, a slit lamp bulb, was incorporated in a multibeam photo-stimulator similar to one previously described[2,3] and mounted on a perimeter arc.

In a proportion of cells the receptive field was 'simple' in the sense that the responses evoked by the exploring light spot were the same throughout the receptive field. In other cases in which the receptive fields were larger the response to light varied across the field. The functional organization of such fields is of interest and a typical result is shown in Fig. 1.

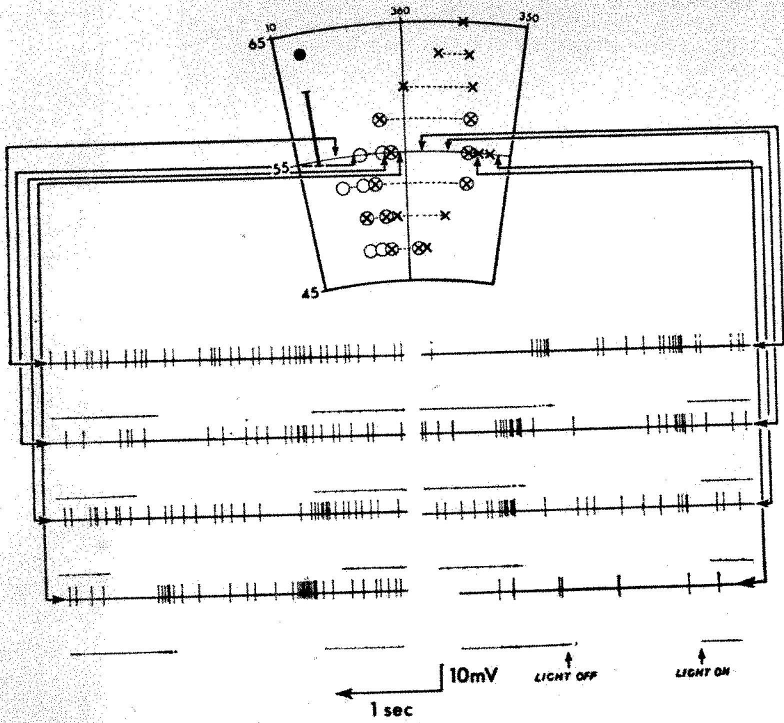

Fig. 1. Receptive field organization of a cell in the rabbit lateral geniculate body. Above, Part of a perimeter chart showing the positions in the rabbit visual field from which responses could be evoked, 360°—vertically above optic axis, 90°—cephalad: the receptive field is therefore in the inferior portion of the rabbit's retina.
×, Off response; ○, on response; ⊗, on–off response. The symbols joined by dotted lines imply that similar responses were evoked in between positions marked. The vertical bar represents a retinal displacement of 1 mm. The small filled circle represents the size of the exploring light spot, stimulus 30′ subtense, 76,000 l./m^2, repetition-rate approximately 2/sec.
Sample records obtained at arrowed points illustrated in lower half of picture right to left. Stimulus single flashes (hand-operated shutter) subtense 45′ intensity 76,000 l./m^2 centred on a 25° constantly illuminated background of 760 l./m^2. Note that when the stimulus lies outside the receptive field light causes neither excitation nor inhibition (that is, slowing of resting discharge). When stimulus lies within a receptive field complex changes in spike-rate occur. The chief changes are that when the left-hand border of the field is stimulated, the geniculate cell gives responses predominantly to the beginning of the light flash and as the stimulus moves across the field the responses change until only the end of the flash is signalled

The upper part of Fig. 1 represents the position of the light source on the perimeter arc, and is in fact part of a perimeter chart. The crosses and circles are placed in that part of the visual field from which responses were obtained. It can be seen that the receptive field is oval and extends in its major axis some 20° of visual angle. The long axis of the field is placed nearly vertical. On-, on-off-, and off-responses were obtained from this field. The specimen records in Fig. 1 show that at the left-hand border of the field the cell responds only to the beginning of the light flash while at the right-hand border the cell responds to the end of the stimulus. In between these points, responses are obtained at both the beginning and ending of the stimuli, the relative preponderance of on- and off-discharges varying across the receptive field. When the stimulus falls outside the field there is no response and no slowing of the spontaneous activity. The area of retina covered by this receptive field was calculated, assuming a posterior nodal distance for the rabbit eye of 8·8 mm, which is a minimal value. The bar in the perimeter chart shows the angle through which the stimulus had to be moved for a retinal displacement of 1 mm.

In the retinæ of all animals investigated[3-6] the receptive fields of retinal ganglion cells are arranged in a different manner to that shown in Fig. 1. The receptive field is circular, and the peripheral portion inhibits the central. The same is true of cells in the cat lateral geniculate body[7]. However, a receptive field organization similar to that of Fig. 1 has been described for cells in the cat visual cortex[8,9]. It appears in the less encephalized rabbit some elements of cortical organization are found in lower nuclei. There are differences between other authors' results[8,9] in cat cortex and the present experiments. The most obvious is that the receptive fields of rabbit geniculate cells are very large—in fact, the example shown in Fig. 1 is one of the smaller fields found. The receptive fields of single retinal ganglion cells are limited by the spread of their dendrites to about 1·5 mm (ref. 10). It is therefore certain that the receptive fields of rabbit lateral geniculate cells are the result of the convergence of several optic nerve fibres which originate in retinal ganglion cells that have overlapping retinal receptive fields. When the intensity of the light stimulus is reduced, receptive fields such as are shown in Fig. 1 become smaller and the responses the same throughout, as though several of the converging afferent fibres had ceased to influence the geniculate cell.

Receptive fields such as shown in Fig. 1 are so large that they can provide little information about the site of a luminous stimulus. On the other hand, it has been found that within the receptive fields there are limited areas which respond when a luminous object moves across them. These areas are frequently located at regions where the type of response changes abruptly, for example, the left-hand border of the receptive field in Fig. 1. The responses to moving objects are in general very much stronger than the responses to stationary flashing lights, and the response only occurs when the object moves in certain directions. The functional organization of the rabbit lateral geniculate body is such that it provides detailed information about the properties of moving objects in spite of the diffuse receptive fields disclosed by stationary flashing lights.

Arousal Reaction in EEG induced by Blood Pressure

It is supposed by several authors[1-9] that adrenaline-induced EEG-arousal, which originates in the mesencephalic reticular formation and the posterior hypothalamus, is caused by a direct action of adrenaline on these structures. Discharges were recorded from single cells within the posterior hypothalamus[10,11]. The firing-rate of these cells was affected by intravenous injection of adrenaline or by mechanically induced changes of blood pressure. There is no effect of adrenaline if the blood pressure is kept constant artificially. We therefore tested the hypothesis that the adrenaline-induced arousal is a secondary effect of the rising blood pressure.

The following experiments were performed on cats with an *encéphale isolé* preparation. It was observed that the EEG-arousal after intravenous injection of adrenaline occurred about 1 sec after the beginning of the rise in blood pressure. Fig. 1 shows that an arousal is also obtained after an increase of blood pressure, which is induced mechanically by a short, strong injection of Ringer solution into the aorta. The high, slow-voltage pattern simultaneously in all leads changes to a fast low activity, which is typical for an arousal reaction. In this case, the arousal occurs at the end of the injection artefact, when the blood pressure has started to rise. Rothballer[9] found a cortical arousal on injection of adrenaline into the mesencephalic reticular formation without changes in the systemic blood pressure. This seems to support the hypothesis of a local action of adrenaline. In our experiments, a local injection of mammalian Ringer solution into the same area also caused a cortical arousal. Therefore, Rothballer's observation might be explained by a stimulation of the cells induced by the mechanical stimulus of the injection.

It can be concluded from our observations that an increase of blood pressure can excite the ascending reticular activating system. The 'pressosensitive area', described by Baust *et al.*[11], is possibly responsible for these effects. This area can be excited by changes in systemic blood pressure as well as by local pressure stimuli as shown in the experiment mentioned here. The fact that injection of vasopressin leads to EEG-arousal[4] also favours our hypothesis.

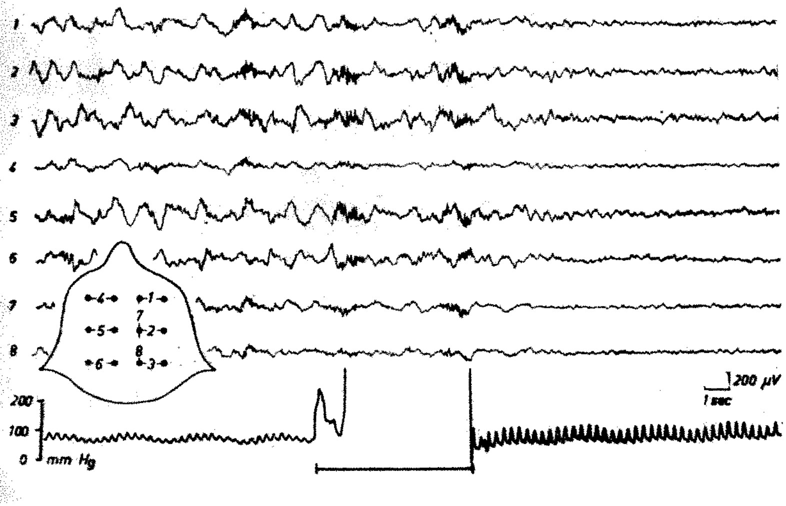

Fig. 1. *Encéphale isolé* preparation of the cat, no narcotics present. Artificial respiration. Lines 1–8, bipolar EEG-records from the cortex; location of electrodes as indicated in the inset. Lowest line, simultaneous blood pressure record in the femoral artery. During the mark (below), 10 ml. of mammalian Ringer solution were injected into the aorta

Serum Cholesterol in Rats intoxicated with Carbon Tetrachloride

Oral administration of carbon tetrachloride to rats causes an elevation in the amount of β-globulins while reducing the albumin, α_1- and α_2-globulins. Subsequent injury by subcutaneous sponge implantation of the intoxicated rats augments both α_2- and β-regions[1]. Since the α_2- and β-globulin regions of rat serum contain lipoproteins[2], the fatty infiltration of the liver might be a responsible factor in some of the changes in electrophoretic patterns which are observed in injured, intoxicated rats. Carbon tetrachloride poisoning is apparently associated with a reduced rate of lipoprotein synthesis resulting in a lowering of the plasma lipoprotein-level and an accumulation of liver lipids[3]. Preliminary experiments, however, showed no intensification of lipoprotein staining (sudan black) of the paper electropherograms obtained with serum from injured, carbon tetrachloride intoxicated rats.

To test this point further, male white rats (Holtzman) were treated by oral administration of 0·1 ml. of carbon tetrachloride mixed with mineral oil (1·1 mixture) per 100 g of body-weight for a total of six days. Some of the poisoned rats were afterwards injured by the subcutaneous implantation (dorsal) of a 200-mg piece of 'Ivalon' sponge after the fifth dose of carbon tetrachloride; a sixth dose was given 24 h later. Normal control rats, control rats receiving 0·1 ml. of mineral oil in six daily doses and rats injured by sponge implantation only accompanied the experiments with carbon tetrachloride.

24 h after the sixth dose of carbon tetrachloride or mineral oil or 48 h after sponge implantation, the rats were anæsthetized with ether and bled by cardiac puncture. The livers were perfused with physiological saline solution, excised and homogenized with an equal volume of distilled water. The homogenates

Table 1. Serum and Liver Cholesterol-Levels in Injured and Uninjured Rats intoxicated by Carbon Tetrachloride

Tissue	Normal control	Mineral oil treated	Carbon tetra-chloride treated	Injury only	Carbon tetra-chloride treated + injury
Serum (mg%)	73·3 ± 11·1 (20)	64·7 ± 5·8 (6)	44·4 ± 8·8 (13)	78·4 ± 16·7 (14)	51·8 ± 11·1 (16)
Liver (mg/g) dry wt.	14·6 ± 2·2 (12)	13·3 ± 3·1 (6)	25·9 ± 7·5 (6)	16·5 ± 3·0 (8)	23·0 ± 5·0 (6)

No. of rats used for each experiment is given in parentheses. All values are presented as the average ± *S.D.*

were treated with 0·084 per cent solution of ferric chloride precipitating agent[4], heated in a boiling water bath for 20 min and then filtered. Cholesterol-levels were determined in serum and in the filtrate of the liver homogenates by the method of Zak[4].

Table 1 contains the average values and standard deviations for all the rats studied. Injury alone, which increases the proportions of α_2- and β-globulins in the rat, caused no changes in cholesterol-levels. Intoxication with carbon tetrachloride decreased the serum cholesterol-levels and simultaneously elevated the concentration in the liver. This is in accord with its hepatic synthesis[5]. Various hepatoxic agents including carbon tetrachloride lower the level of serum lipids while at the same time causing their hepatic accumulation perhaps by interfering with the synthesis of plasma lipoproteins[3,6,7]. Our results show that injury neither reverses this interference in plasma lipoprotein synthesis nor promotes a release of lipid accumulated in the liver.

HISTOLOGY

Determination of Refraction Index and Thickness of Histological Sections

In connexion with an investigation into the mechanism of vision of some Arthropoda it was necessary to determine the refractive index, *n*, of the dioptric tissues of an ommatidium. Owing to the small dimension of these tissues, even in such a big insect as the dragon fly, *Aeschna*, it would be very difficult to measure this index with ordinary refractometers because the cells in question cannot be separated without damage. Thus *n* must be determined directly by using histological sections. Due to the fact that cells are never absolutely homogeneous it is possible to determine only an average value of the index. Therefore, the more accurate but circumstantial methods can be replaced by the old and well-known methods of de Chaulnes (1768) if improved in the following way in which only a modern microscope together with a special glass slide device are needed.

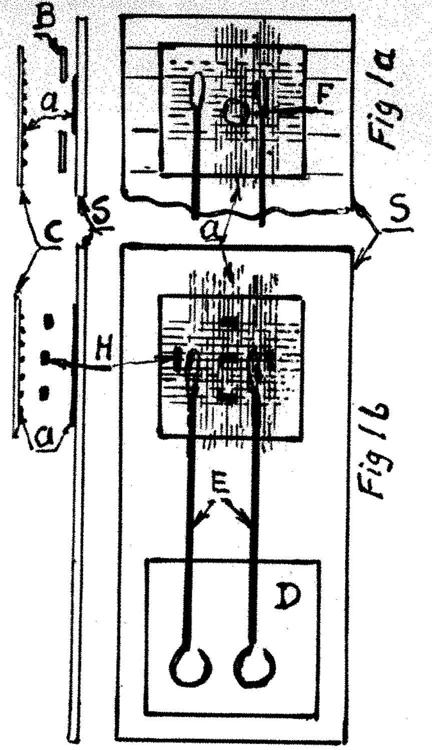

Fig. 1. *a*, Strokes of aluminium; *B*, brackets of cover glass; *C*, cover glass; *D*, metal sheet; *E*, stainless steel springs, fixed to *D*; *F*, drop of liquid or air bubble; *H*, piece of tissue; *S*, glass slide

For the sake of simplicity, I will begin with the refractive index of a liquid (Fig. 1*a*). An ordinary, fairly even glass-slide, *S* (0·8–1·0 mm), is on one side, over an area of about 10 × 10 mm, covered with strokes of metallic aluminium which are easily drawn with a moderately sharpened edge of a piece of aluminium sheet wetted with a drop of water. The aluminium marks, drawn parallel at a distance of 0·2–0·5 mm, will firmly adhere to the glass. The microscope will show that the marks consist of an immense number of very small grains of aluminium. The overposing but not the rest of the marks can and may be removed by a razor blade. In the same way, an ordinary even cover glass, *C* (18 × 18 mm), may also be covered with aluminium marks, *a*. In order not to break this thin glass it should be glued beforehand to a glass slide by wax. Another cover glass is cut in two parts, brackets, *B* (9 × 18 mm), and glued permanently to the glass-slide, *S*, by Canada balsam or resin, one part on each side of the aluminium-marked area. To secure an even upper surface of the two brackets another slide should be pressed on the top of them until the balsam has dried. The aluminium-marked cover glass is now placed on the top of the brackets and with the aluminium strokes downwards and perpendicular to the strokes of the slide. Further, this cover glass is pressed to the brackets by a simple device: on a piece of brass sheet, *D* (about 1 × 20 × 25 mm), are fixed two small wires of hard stainless steel, *E*, of about 0·5 mm diameter. The brass sheet is glued to the slide by a wax–resin mixture in such a way that the flattened ends (about 0·1 mm) of the wire springs may press the cover glass firmly to the brackets in order to prevent the capillary

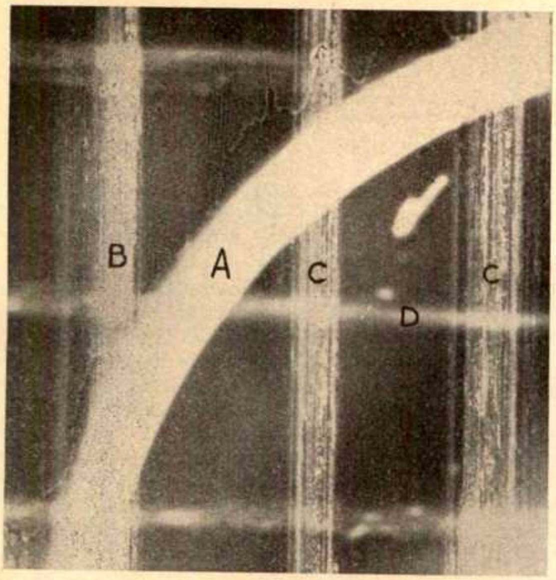

Fig. 2. *A*, Border-line of a droplet of water; *B*, aluminium marks on the glass slide, distinctly seen through air; *C*, aluminium marks on the glass slide, distinctly seen through the water; *D*, aluminium marks on the cover glass, seen very dimly

force of a liquid from lifting the glass. Now we have an interspace between two fairly parallel aluminium-marked glass surfaces, the marks forming a cross net (Fig. 1).

With a microscope magnification of about × 400–800 in light field or more suitably in dark field one is able to focus very sharply on the two marked surfaces. With air in the interspace ($n = 1{\cdot}000$), the microscope-micrometer reading being a for the upper and b for the lower surface, then the thickness of the interspace $d = a - b$. A very small droplet, F, 0·5–1 mm^3, of a liquid of refraction index n_1 may now be put in the midst of the interspace, preferably not into contact with the brackets. Along the borderline of the droplet one will find many points where can be seen, at the same time but with altered focusing, the aluminium marks of the slide through the air on one side and through the liquid on the other side of this borderline, as well as the marks of the cover glass (Fig. 2*b*). If the reading of the slide marks through the liquid is b_1, then $n_1 = \frac{a-b}{a-b_1}$. This simple formula can easily be checked: the interspace = the exact thickness of the brackets can be controlled by a micrometer, and may be d_0. A small correction factor, c, for the difference between d and d_0, that is, $d_0 = d + c$, can, if desirable, be introduced, *inter alia*, due to the fact that the rays through the microscope are not exactly central. Further, the distance $a - b_1$ can be controlled by a liquid of known refraction index, for example, distilled water of $n = 1{\cdot}333$ ($= 4/3$). For the calculation put $b - b_1 = s$. Then we may write the equation $\frac{1}{n_1} = 1 - \frac{s}{d+c}$. If, for example, $d = 127\mu$ and $s = 33\mu$ and $n_1 = 1{\cdot}333$ then c will equal 5. If this value is inserted the equation will be fairly good for other liquids or substances provided the same glass slide device is used.

The determination of refraction index of a biological tissue ought preferably to be made in fresh material or fixed in a medium which will not shrink or swell the tissue appreciably, for example, an isotonic 4 per cent formol solution. The tissue may be cut in a freezing-microtome. The determination of n of the cornea (subst. propria) of a compound eye at right angles to the optical axis of the eye may be used as an example. About 10 sections, 80μ thick, were cut perpendicular to the cornea surface and distributed evenly on the aluminium-marked area of a glass slide. As before, a marked cover glass was placed on top of the sections with tiny springs pressing it to the sections and with, for example, distilled water filling up the interspace and surrounding the sections. In order to prevent any bending of the cover glass a section ought to be placed right under the tip of a spring. Brackets for the cover glass can also be made by small pieces of paraffin cut to the same thickness as the sections. Now one will find many points where, in the same field of view and without moving the slide, one is able to focus on the marks of the cover glass as well as on those of the slide through the water and through the cornea section, the readings being respectively a, b_1 and b_c. Put $a - b_1 = d_1$ and $b_c - b_1 = s$. The index of water or any other reference medium $= n_1$. Then we get for the corneal index $n_c = \frac{a-b}{a-b_2}$, and if this is divided by the previously mentioned equation we get $n_c = n_1 \frac{a-b_1}{a-b_2}$ or $n_c = n_1 \frac{d_1}{d_1 - s}$, and if we invert the equation and insert the correction factor and use water as reference medium: $\frac{1}{n_c} = \frac{3}{4}\left(1 - \frac{s}{d_1 + c}\right)$.

Once c has been evaluated, one has only to measure the three distances a, b_1 and b_c or the difference $b_c - b_1$. For the example given the figures from a statistic series of 25 measurements were found to be: $\frac{1}{n_2} = \frac{3}{4}\left(1 - \frac{4{\cdot}56 \pm 0{\cdot}40}{75{\cdot}20}\right)$. Thus the refractive index will be $1{\cdot}42 \pm 0{\cdot}01$, which seems to be a fairly satisfying value.

This method can also be used to find the approximative thickness and total shrinkage of a tissue, already embedded in, for example, Canada balsam or glycerol–gelatin if the embedding is made between aluminium-marked glasses and the embedding medium is known. If the aluminium marks are not too broad they will scarcely disturb the picture even at great magnifications.

It is obvious that the accuracy of this method is dependent on many factors. Homogeneity, transparency and histological treatment are, of course, important; but this is true for every method. The formula shows, however, that the accuracy of a measuring depends on the exactitude with which the ratio s/d can be determined. An advantage of this simple method compared with the more accurate methods based on total reflexion, for example, refractometers of Pulfrich or Abbe, will, however, be that which obtains the average refractive index of a tissue substance and not only the index of its surface.

The refractive index, n, is important in many ways, not only by itself because it is correlated to other properties, for example, the dielectricity-constant of which n is the square root.

PATHOLOGY

Association of Cell Surface Antigens with Microsomal Membrane Fractions derived from Ehrlich Ascites Carcinoma Cells

ASCITES tumour cells have been used widely in the study of the localization and mode of action of the cytotoxic antibodies produced by the administration of whole cells to heterologous animals[1-5]. Such investigations have indicated that the cytotoxic antibodies exert their effect on the cell membrane. Recent investigations of Ehrlich ascites carcinoma cells suggest that the surface membrane of these cells form small vesicles on cell rupture, and that these sediment with the microsomal membranes on differential centrifugation[6,7].

The work reported here shows that the microsomal membranes and their various sub-fractions contain potent antigens capable of forming both cytotoxic and agglutinating antibodies to Ehrlich ascites carcinoma cells when injected into rabbits.

Microsomal membranes were prepared from Ehrlich ascites carcinoma cell microsomes by centrifugation in sucrose density gradients as described previously[6,7]. Crude membrane preparations contained all the membrane material floating at a density of 1·19 after centrifugation at 105,000*g* for 18 h in a Spinco *L* ultracentrifuge with a 40 rotor. This preparation contained 0·37 μmole phospholipid phosphorus and 0·02 μmole *N*-acetylneuraminic acid per mole of protein and was free of ribonucleic acid. The microsomes were also further separated into a membrane fraction floating at a density of 1·16 (0·46 μmole lipid phosphorus and 0·028 μmole *N*-acetylneuraminic acid per mg of protein), a second fraction floating at density 1·16 (0·40 μmole lipid phosphorus and 0·017 μmole *N*-acetylneuraminic acid per mg of protein) and material sedimenting into a pellet at density 1·17, containing the ribosomes and 'rough' membranes.

Prior to immunization the various fractions were re-sedimented in 0·25 M sucrose, washed once in 0·15 M sodium chloride and suspended in 0·15 M sodium chloride for immunization.

Adult New Zealand white rabbits weighing about 2 kg were used for immunization purposes. A series of three intravenous injections of antigen was given. Each injection consisted of 0·5 ml. of a saline suspension of membrane material containing 415 μg protein per ml. (66·5 μg protein nitrogen). Immunizations were given on days 0, 2, and 4. Serum samples were collected prior to the first immunization, after the end of the first week (day 7–9) and after the end of the second week (day 14–16) in most instances. Blood samples were allowed to clot at 20° C for 2 h. The serum was removed from the erythrocytes, heated at 56° C for 30 min to inactivate complement, and stored at −40° C until used.

Antibodies capable of agglutinating Ehrlich ascites carcinoma cells were present in the sera collected within 7 days after initiation of immunization with crude membrane material. Sera collected after 12 days contained agglutinating antibodies detectable in dilutions of up to 1 to 2,400 using 4×10^5 cells per ml. in the assay system. No agglutination was observed after 1 h at 4° but agglutination was readily apparent within 15 min at 37°. Neither complement nor divalent cations were necessary for agglutination. Pre-immunization sera did not cause any agglutination reaction. As indicated by an experiment where the antiserum was absorbed with 20 cell equivalents of various cell particulates (Table 1), there is little cross-reaction with nuclei, mitochondria and lysosomes.

Table 1

Anti-membrane serum absorbed with	Agglutinin titre
Microsomes	<1 : 100
Lysosomes	1 : 750
Mitochondria	1 : 2,000
Nuclei	1 : 2,000
Unabsorbed	1 : 2,400

Similar studies using the various microsome subfractions described indicate that the antigen responsible for the production of the agglutinating antibody is associated with the membranes of lowest density.

All sera were examined for their activity in the immune adherence phenomenon[8,9] when reacted with fresh Ehrlich ascites carcinoma cells, guinea pig complement, and human erythrocytes. Antibodies capable of reacting with whole Ehrlich ascites carcinoma cells were found in all serum samples obtained after immunization, and were absent from all the control (pre-immune) sera. Using hæmagglutination patterns as an end-point serum dilutions up to 1 : 16,000 were found to give a significant reaction in the immune adherence system. Examination of the immune adherence mixtures by phase contrast microscopy revealed erythrocytes firmly adherent to the surface of all Ehrlich ascites carcinoma cells (Fig. 1).

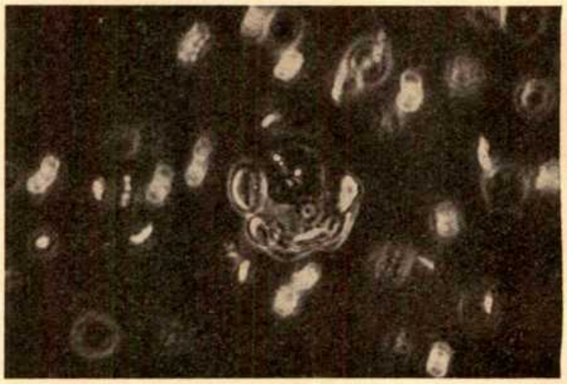

Fig. 1. Immune adherence of human erythrocytes to Ehrlich ascites carcinoma cell in presence of rabbit antiserum against EAT microsomal membrane and complement. The characteristic vacuoles of the EAT cell are visible overlying the nucleus. The non-adherent erythrocytes have been set in motion by tapping on the coverslip. (Phase contrast × *c*. 900)

The action of complement on antibody sensitized cells was accompanied by marked swelling of the cells, presumably due to membrane alterations which were reflected biochemically by: (1) leakage of RNA and soluble nucleotides from the cells; (2) increased protein leakage from the cells; (3) an increase in the ATPase activity of antibody-treated cells which is due to the development of ATP permeability of the cell membrane, thus allowing externally added ATP to reach intracellular loci of ATPase activity such as mitochondria. This alteration of ATPase activity of antibody-sensitized Ehrlich ascites carcinoma cells by complement provides a very sensitive biochemical assay for the presence of cytotoxic antibodies. Pre-immunization sera, with or without complement, showed no cytotoxic effect. Neither the agglutinating nor the cytotoxic antibodies were inhibited by the presence of a 100-fold excess of *N*-acetylneuraminic acid, which is known to be located on the surface of these cells and in the microsomal membranes.

The foregoing results support previous work on the antigenicity of microsomal membranes[10], and provide additional evidence for the localization of the surface membrane of Ehrlich ascites carcinoma cells in the microsomal membranes following cell rupture.

Dialysable Peptide as the Causative Factor in Experimental 'Allergic' Encephalomyelitis

PREPARATIONS of soluble proteins from brain and spinal cord which were used for the production of 'allergic' encephalomyelitis in experimental animals have been described[1-4]. Roboz *et al.*[5] reported a soluble, collagen-like protein apparently of different nature. Others[6-10] have reported on the association of encephalitogenic properties with proteolipids. Although its chemical pathogenesis is unknown, the disease is almost generally accepted to be an immunological reaction and we therefore prefer to describe chemical fractions obtainable from nervous tissue as 'encephalomyelitis-promoting' (EP) rather than 'encephalitogenic'.

Experiments were undertaken in this Department to determine whether the EP factor, which seemed from experiments on soluble proteins to be a histone, might be present also in proteolipid and other extractives known to be encephalitogenic in combination with Freund's adjuvants. We have found that a histone preparation from bovine cord contained much protein-bound, peptide-rich material which had most, if not all, of the EP activity of the original preparation when separated from the histones by dialysis at *p*H 9. Freed of this material, the basic proteins lost all, or nearly all, EP activity but were shown by zone electrophoresis still to give the same qualitative protein pattern as before removal of the active peptides. The dialysed peptides showed no detectable protein.

Histones with EP activity were also obtained both from the upper aqueous and from the lower chloroform phases yielded in the preparation of proteolipids by the method of Folch and Lees[11], but there was also EP activity in a protein-free fraction from the aqueous phase. Moreover, the paper partition chromatographic pattern of alkaline dialysate of proteolipid (ninhydrin coloration) was found to be identical with that of the histone dialysate from potassium chloride extracts. An alkaline dialysate of an emulsion of the solids of bovine spinal cord soluble in light petroleum ether also contained peptides although its EP activity and that of peptide associated with proteolipid are only now under test.

The soluble proteins were prepared from partially defatted spinal cord by extraction first with 10 per cent potassium chloride and precipitation with fully saturated ammonium sulphate followed by dialysis at neutral *p*H and freeze-drying of the non-dialysable residue. This material had strong EP activity, 50γ injected intradermally in Freund's adjuvants producing paralysis in 8 of 10 guinea pigs. Electrophoretically, 10 protein fractions were present including at least two major histone fractions. The non-histone fractions were confirmed to be inactive but, surprisingly, the purified histones from this material were almost inactive after conventional separations either by ion-exchange celluloses or sucrose density-gradient electrophoresis. Both types of method had involved dialysis of the protein fractions at *p*H 8–9. In several trials on the effects of sucrose and alkali, individually and combined, on soluble protein samples with known EP activity, it was found that mere dialysis of the EP materials in an alkaline medium (*p*H 8·6) was enough to release most of the EP activity into the dialysate, although, qualitatively, the electrophoretic pattern of the non-dialysable residue remained unaltered.

Further support for the foregoing findings derives from the preparation of highly active material obtainable by 10 per cent potassium chloride extraction at *p*H 2 (10 g from 2 kg fresh cord). Electrophoretically, both on cellulose acetate strips and in starch gel it yielded good separation of seven basic proteins and the extract was free of acid proteins. Its EP activity was high (8 of 10 animals were paralysed) at 10-γ dose-levels. On dialysis at *p*H 9, from 1 g of these histones 675 mg of solids passed into the dialysate, about one-fifth being peptide, which could be partially separated from accompanying amino-acids and sugars by passage through 'Sephadex *G*–25'. This dialysate showed high EP activity even at 5-γ doses while the non-dialysable solids (proteins) even at dose-levels of 1 mg were only slightly active.

Galactose Metabolism : Phenotypic Differences among Tissues of a Patient with Congenital Galactosæmia

It has recently been reported that two patients who had the characteristic syndrome of congenital galactosæmia as infants, and who lack gal-1-P uridyl transferase in their red blood cells, are nevertheless able to oxidize galactose-1-^{14}C to $^{14}CO_2$ *in vivo* in a near-normal fashion[1]. It is therefore apparent that some tissues within these individuals must be capable of metabolizing galactose. Further studies on one of these subjects (T. B.), a 30-year-old Negro who was the first case of galactosæmia reported in the American literature[2], have inquired into possible tissue differences with respect to the presence or absence of the metabolic derangement typical of galactosæmia.

Five different tissues derived from T. B. have been examined *in vitro* for their ability to metabolize galactose. The results obtained with white blood cells[3] and skin cells in tissue culture[4] have been reported previously. These results, together with those obtained for hæmolysates, intestinal mucosa and liver, are presented in Table 1. Of the tissues studied, only liver compares favourably with the normal in its ability to oxidize galactose-1-^{14}C to $^{14}CO_2$. Thus it would appear that this case represents a situation in which marked differences exist among tissues of a galactosæmic subject with respect to their galactose-oxidizing capacity relative to that of their normal counterparts. The implications of these observations in relation to galactose metabolism *in vivo* are not immediately apparent and deserve further study.

The pathway by which the liver of this galactosæmic patient is able to oxidize galactose deserves further consideration. Anderson *et al.*[5] reported that liver obtained by needle biopsy from the same patient had about 5 per cent of the normal ability to incorporate ^{14}C-galactose-1-phosphate into uridine nucleotide in the presence of uridine diphosphoglucose and uridine triphosphate, a finding which indicated a marked reduction of transferase activity as well as of any related alternative pathway. However, the subject was capable of forming glucosiduronic acid from galactose at a normal rate[6], an observation which is consistent with the present results obtained on the patient's liver and the *in vivo* results reported previously[1]. These findings can be explained on the basis that either the low activity detected by Anderson *et al.* is sufficient to account for the results of the *in vivo* and present *in vitro* studies, or that the pathway of galactose metabolism in the liver of this subject differs from that of the normal.

Table 1. OXIDATION OF GALACTOSE-1-^{14}C TO $^{14}CO_2$ BY VARIOUS TISSUES

Tissue	Subjects		B/A
	Subjects Non-galactosæmic (*A*)	Subject T. B. (*B*)

	mμM $^{14}CO_2$/ml. packed R.B.C./h		
Hæmolysate§	5·9 (1)	0	0
	mμM $^{14}CO_2$/100 mg tissue/h		
Intestinal mucosa¶	60 (1) 89 (1)	1·7	0·023
Liver‖	1·5 (1) 0·9 (1)	0·9	0·75

Nos. in parentheses refer to the No. of subjects.

* Data calculated from the paper by Weinberg (ref. 3).

† *S.E.*

‡ Data calculated from the report of Krooth and Weinberg (ref. 4).

§ A 20 per cent hæmolysate was prepared by freezing and thawing R.B.C. suspended in Krebs phosphate buffer, *p*H 7·4, after remova of W.B.C. by centrifugation. The incubation medium contained 2 ml. of hæmolysate, 0·1 μc. galactose-1-^{14}C (4·72 μc./mg), 1·1 μM ATP and 0·54 μM TPN. $^{14}CO_2$ was collected as described previously (ref. 7).

¶ Suction biopsy of the small intestine mucosa was performed perorally with the instrument described by Brandborg *et al.* (ref. 8), and comparisons between normal and T. B. were made using tissue from the upper jejunum. 5 mg pieces of tissue were incubated in 3 ml. of Krebs bicarbonate buffer, *p*H 7·4, containing 0·15 μc. of radioactive galactose. Each value represents the average of duplicate determinations.

‖ Liver biopsy of T. B. was performed with a Menghini needle. The 15 mg of tissue were cut into four segments and incubated as described for intestinal mucosa. One piece of tissue was boiled for 2 min before incubation and served as a blank. Liver biopsy of controls was obtained at surgery from two individuals suffering from gall bladder disease. The surgical specimen was cut into 5–10 mg segments for incubation. Incubations were performed in triplicate.

The finding of definite phenotypic differences among several tissues from a single galactosæmic patient when studied for their ability to oxidize galactose *in vitro* indicates that galactosæmia is a more complex disease entity than has been appreciated hitherto.

Metaplasia of Aortic Connective Tissue to Cartilage and Bone induced by the Intravenous Injection of Papain

The effect of intravenous papain on the cartilage matrix has been reported by L. Thomas[1]. Recently we have been investigating the acute lipæmia induced by the injection of papain solution in adult rabbits[2]. At the end of each experiment, the animals were killed by air embolism and autopsies were performed. Several of these experimental animals showed lesions in the ascending aorta and the arch, and to a lesser extent in the upper portion of the descending aorta. This communication deals with the description of these lesions and of the conditions under which they were developed.

Grossly, the lesions appeared well delineated by a halo of raised tissue with irregular surface and edges

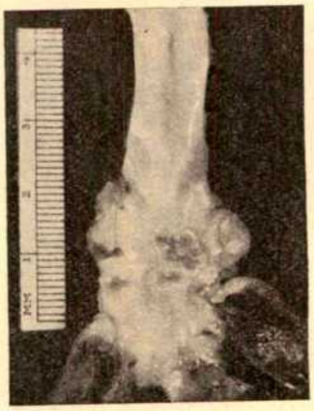

Fig. 1. Aorta of rabbit No. 89, male, 5,670 g, injected once with 15 mg papain/kg body-weight

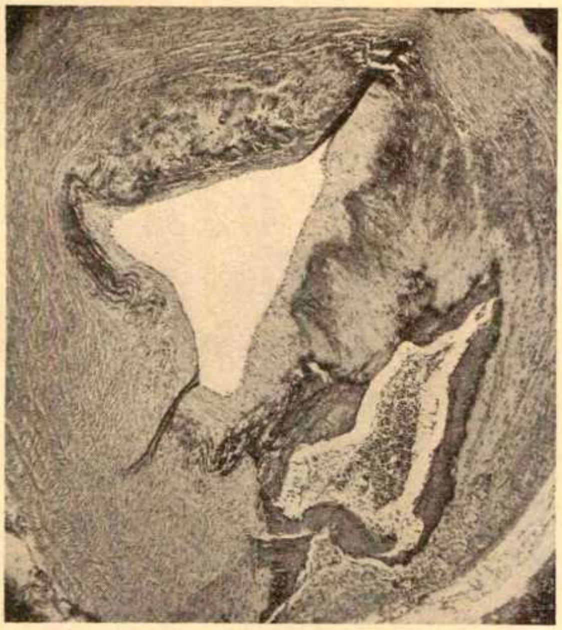

Fig. 2. Photomicrograph of a lesion in the innominate artery of Rabbit No. 137, male, 4,550 g, injected once with 7·5 mg papain/kg body-weight (hæmatoxylin and eosin; × c. 45)

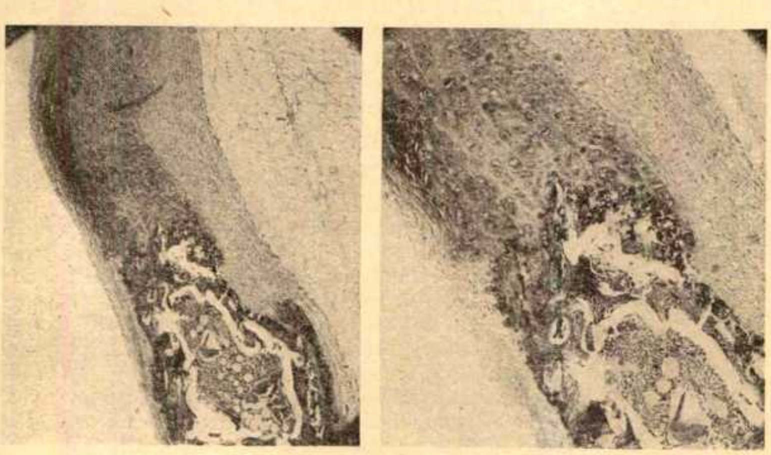

a *b*

Fig. 3. *a*, Photomicrograph of a lesion shown on Fig. 1 (hæmatoxylin and eosin; × *c*. 53); *b*, part of *a* (× *c*. 80)

(Fig. 1). The lesions were hard and presented considerable resistance to the cutting instrument. Their diameters varied from 8 to 12 mm each. No constriction of the lumen was evident, more than that produced by the protruding tissues. In some cases the lesions extended into the major vessels arising from the aortic arch (Fig. 2).

The changes involved primarily the media, but at their maximum point they also involved the entire wall (Fig. 3). Toward the periphery of the lesion, there appeared increased deposition of material, positive to periodic acid–Schiff reaction, presumably polysaccharides in nature. The same material was intensely stained with the usual hæmatoxylin–eosin. In this area, the fibrocytes were quite prominent, and some fibroblastic activity was evident. Many of the fibroblasts were surrounded by a halo of polysaccharides. Further centrally occasional chondrocytes appeared in an environment intensely positive to periodic acid–Schiff. Eventually, the chondrocytes became so numerous as to form true cartilage. In this area calcium deposits appeared which eventually proceeded to form bone with mature bone trabeculæ. Here, the entire thickness of the aorta was replaced by the bone and cartilage and these were covered by a thin layer of connective tissue and endothelial cells. The centre of the ossified area contained active bone marrow. The process thus described is slowly reversed on the other side of the lesion until normal aortic tissue becomes again evident.

All animals in these experiments weighed 2,500–5,000 g. They were maintained on laboratory rabbit purina chow *ad lib*. One single injection of purified (but not crystalline) papain was given intravenously. The papain was prepared as recommended by L. Thomas[1]. The dose varied from 7 to 15 mg/kg body-weight. Usually solutions of 2–3 per cent were used for injection. The animals were killed 3–6 weeks after the injection of papain. The lesions described here appeared in animals killed at least 3 weeks after the injection of papain. Smaller lesions without cartilage and bone formation and without bone marrow were quite regularly seen as early as one week after receiving one injection of 7–10 mg/papain/kg body-weight.

The mechanism of metaplasia of connective tissue elements in adult life towards cartilage and bone has been speculated on by pathologists and histologists, but without concrete evidence. As a likely explanation for this metaplasia I would like to refer to the effect of papain on the cartilage matrix. I have shown[3] that the injected papain induces hydrolysis of the cartilage matrix and that the products of such hydrolysis, namely, sulphated polysaccharides, circulate in the blood in high concentrations and become deposited in various organs[4].

It would seem reasonable that one such site would be the aorta, where polysaccharides are evident in excess in a variety of disorders. How the metaplasia arises from this deposition is only a matter of speculation. That papain as such has a direct action on the aorta seems rather unlikely in view of the conclusive evidence that the intravenously injected papain is rapidly inactivated and is completely destroyed within 10–15 min after it is injected[1]. Direct trauma to or of the aorta could be of significance for the development of these lesions even though there was no evidence of trauma in these experimental animals.

Finally, these lesions offer a possible tool for the study of connective tissue metaplasia either in experimental animals or in cases of delayed callus formation in fractures.

BIOLOGY

Inhibition of Fruit-Bud Formation in Apple with Gibberellic Acid

Bradley and Crane[1] have reported inhibition of fruit bud formation by gibberellin in apricot, almond, cherry and plum; Hull and Lewis[2] in peach and Griggs and Iwakiri[3] in pears. Gibberellic acid also inhibits flower formation in *Fragaria* spp.[4] and *Kalanchoe blossfeldiana*[5]. No report of inhibition of fruit buds in apples has been found, although Hull and Lewis[2] obtained no effect on flowering or vegetative growth from a single application of a spray of 100 p.p.m. of gibberellin.

An experiment at Mylnefield has shown that gibberellic acid can cause inhibition of fruit-bud formation in apples without affecting bursting of buds in the following spring. In the summer of 1960 branches of six varieties of apples were selected, and treatments were allocated at random so that each treatment was applied to two branches on each variety. Drenching sprays of gibberellic acid (*YF* liquid formulation supplied by Plant Protection, Ltd.) at either 10 or 50 p.p.m. were applied to the leaves and stems of the branches at approximately weekly intervals from May 31 until August 29, making 14 applications in all. Control branches were not sprayed. Counts of buds were made in spring 1961 and the records are presented in Table 1. Some branches were broken in winter and this accounts for the missing data. Taking the six varieties and both levels of treatment together, the percentage of spurs bearing blossom clusters was reduced from 40 per cent on unsprayed branches to 14·7 per cent on sprayed branches. There was also a pronounced inhibition of fruit bud formation on the new wood of the variety Laxton's Superb.

Table 1. EFFECT OF GIBBERELLIC ACID (GA) ON FRUIT-BUD FORMATION IN APPLE

Variety	No GA		10 p.p.m. GA		50 p.p.m. GA	
	No. of fruiting spurs or buds	No. of vegetative spurs or buds	No. of fruiting spurs or buds	No. of vegetative spurs or buds	No. of fruiting spurs or buds	No. of vegetative spurs or buds
Benediction (spurs)	12	38	1	27	0	27
Delicious (spurs)	9	27	—	—	1	22
Madresfield Court (spurs)	13	8	7	8	0	11
McIntosh Red (spurs)	4	9	—	—	1	16
Lord Derby (spurs)	11	12	0	31	0	20
Laxton's Superb (spurs)	15	2	5	2	14	18
Laxton's Superb (buds on new wood)	42	1	4	57	0	47
Total (spurs and buds)	106	97	17	125	16	161
Per cent fruiting	52·2		12·0		9·8	

The same rates of application on plums caused either death (50 p.p.m.) or a severe delay in bud break (10 p.p.m.) as has been reported before[1].

Microscopic examination of buds of *Prunus* by Bradley and Crane[1] showed that growth of both fruit and vegetative buds was retarded by gibberellin. However, because growth of fruit buds was retarded at lower levels of gibberellin than were required to retard vegetative buds they suggested that gibberellins may be specifically blocking floral initiation as well as generally retarding cell division at higher concentrations.

Apple buds were not examined microscopically at Mylnefield, but the fact that there was no delay in bud break in spring suggests that any check to bud growth that there may have been during treatment was not severe. Nevertheless an indirect morphological effect rather than specific inhibition of flower induction remains possible, especially as Fulford[6] found that small differences in numbers of nodes in apple buds appeared to determine the presence or absence of flowers.

It is possible that sprays of gibberellic acid could be used to restrict flower bud formation in the non-fruiting year of biennial bearing apple trees.

The assistance of Mrs. R. N. Smith is gratefully acknowledged.

A Species of *Tetrahymena* from the British Garden Slug *Milax budapestensis*

HISTOPHAGOUS species of the ubiquitous holotrich genus *Tetrahymena* (Ciliata: Hymenostomatida) have been reported from the body spaces and tissues of a variety of vertebrate and invertebrate organisms[1]. Slugs and snails have been named as hosts in a dozen widely scattered and usually very brief reports published during the past 30 years, the molluscs having been collected in South Africa, the Congo, Poland, Nova Scotia, and from sites in California, Oregon, Virginia, and Illinois in the U.S.A. In work by one of us (A. C. S.) on osmotic relations in gastropods, a small (about 40μ long) ciliated protozoon was detected in a blood sample withdrawn from one of the common British garden slugs, *Milax budapestensis* (Hazay, 1881), collected in the University of Exeter greenhouse. Subsequent examination of additional specimens of this species of keeled slug revealed similar infections; the ciliates were apparently present throughout the alimentary tract and in the liver, although not occurring in great numbers. Study of the protozoon by silver impregnation[2] and other techniques made possible its identification as a strain of *Tetrahymena limacis* (Warren, 1932) Kozloff, 1946, in agreement with the careful redescriptions of this species published by Kozloff[3-5].

The finding of *T. limacis* in British slugs extends its geographical host range, which one may now suspect is truly world-wide. Of more significance, however, is the relationship of this species of *Tetrahymena* to its host, especially in comparison with other tetrahymenid ciliates which also have been said to exhibit facultative parasitism. Of the 13 species of *Tetrahymena* described so far, 8 have been implicated in some degree of parasitic or commensalistic association with vertebrate or invertebrate hosts; only 5 have been found solely in free-living (fresh-water) habitats. In the total range, from a completely non-parasitic existence or merely occasional or accidental parasitism to incipient or possibly true obligate parasitism, *T. limacis* appears to fall near the latter extreme. The whole series has very recently been considered of possible evolutionary significance in the origin of the endoparasitic habit from a free-living ancestry[6].

T. limacis has no encysted stage in its life-cycle and is seldom found outside its host, although it can be cultured with facility in simple media in the laboratory. It has a mouth and an active contractile vacuole, but this also holds for numerous species of ciliates long known to be obligate endoparasites. Experimental work[4,5] suggests that the organism enters a fresh host in nature via fæcal contamination in the host's edaphic environment. Infection is not fatal and the number of ciliates per host is never high: these points particularly stand in contrast with the situation observed in such species as *T. chironomi*, *T. corlissi*, and *T. stegomyiae*[1].

All the species of *Tetrahymena* involved in any degree of parasitism *sensu lato* are histophagous, tissue-eating, ciliates. One species, *T. rostrata* is, in addition, an edaphic form when found free of its hosts, which, like *T. limacis*, include snails and slugs; but it is not difficult to make a taxonomic distinction between these two species on both life-cycle and morphological grounds. Whether *T. limacis*, unlike most others in the series alluded to here, may more properly be considered facultatively free-living, thus being an obligate rather than facultative parasite of its host, is an important and intriguing question which both demands and warrants further investigation.

Furunculosis in Salmon Kelts

DURING the spawning season of 1960–61 investigations were initiated in Ireland into the occurrence of furunculosis among spawning and spawned salmon. In that season 159 kelts were examined from four rivers; only one fish gave a positive reaction[1]. These investigations were continued during the spawning season of 1961–62 when 49 kelts were examined. All fish were dead when taken from the water. The distribution and results are given in Table 1.

Table 1

River	No. of kelts examined		Hatchery or naturally spawned	Result of test	Period
	Male	Female			
River Owenea (Co. Donegal)	25	11	All hatchery stripped	All negative	January 9–February 7, 1962
River Erne (Co. Donegal)	4	2	All naturally spawned	All negative	March 15–May 29, 1962
River Blackwater (Co. Waterford)	—	1	Hatchery stripped	Positive	December 6, 1961
River Boyne (Co. Meath)	1	—	Naturally spawned	Positive	December 3, 1961
River Lee (Co. Cork)	2	—	Hatchery stripped	Negative	January 23, 1962
River Moy (Co. Mayo)	3	—	Naturally spawned	1 positive	March 1–3, 1962
Total	35	14		46 negative 3 positive	

As can be seen, three fish (6·1 per cent) gave a positive reaction.

I thank Mr. E. Murphy, of the Veterinary College of Ireland, Ballsbridge, Dublin, who undertook the bacteriological examination of these fish.

Development of a DDT-Tolerant Strain of Laboratory Mice

A COLONY of mice selected by breeding the survivors of DDT treatments showed a definite tolerance to the insecticide by the ninth generation. The level of this tolerance was assessed by comparing the LD_{50} values with those of a control colony started from the same parent colony and reared under similar conditions.

In the summer of 1959, a colony of white laboratory mice, *Mus musculus* L., was divided into two parts: one part was maintained as a control; in the other, each generation was subjected to treatment with DDT. DDT dissolved in sesame oil was administered by intraperitoneal injection at the rate of 0·01 c.c. solution/g mouse weight and expressed in mg of DDT/kg mouse weight. All treatments to select tolerant mice were made at the age of four weeks. In order to reduce variation in weight between individuals in different litters, all litters were culled back to nine individuals per doe when the young were a week old. The doe was removed from the litter at approximately 3½ weeks. After treatment, mice were kept until eleven weeks old, at which time they were mated.

The original LD_{50} value for mice from the control colony and parent colony at four weeks of age was estimated to be approximately 500 mg/kg. At generation four, the LD_{50} value for the control colony males was estimated at 500 mg/kg and for the females at 550 mg/kg, whereas the colony under DDT pressure had an estimated LD_{50} of 650 mg/kg for males and a proportionately higher value for females. These approximate LD_{50} values were based on selected arbitrary dosages decided on after numerous preliminary tests.

At the ninth generation, using the method of moving averages and tables published by Weil[1], the LD_{50} value and confidence interval for the control colony males was estimated as 495–541–590 mg/kg and for females as 526–567–612 mg/kg. The value for the colony under DDT pressure was 905–944–983 mg/kg.

Observations were also made on the reaction of individuals to the treatment. Members from the colony under DDT pressure reacted much more slowly to the effects of the treatment, and the symptoms caused by the insecticide were much less noticeable until death was imminent.

The foregoing observations indicate that a change is occurring in the colony of mice in which each generation is subjected to DDT pressure. Whether this change may be classified as a true resistance to the insecticide comparable with that found in many insect species is uncertain. With insects, the change to resistance is frequently slight for the first few generations and then increases rapidly. The tolerance-range of the mouse to DDT is very narrow. The dosage to produce an LD_{50} for the tolerant (selected) colony is, at the ninth generation, only 1·7 times higher than that of the LD_{50} value for the control colony. This increase of the dose by 1·7 times is, however, sufficient to kill all the control colony animals. This small difference is therefore a very significant one.

We think that with the development of this DDT-tolerant colony of mice, a useful biological tool has been produced for use in further study of the complex subject of chemical tolerance.

Spurious Negative Correlation between Age and Weight per Day of Age in Beef Calves

Weight per day of age is commonly used to assess growth in beef calves. It can be shown that there is a very high correlation between weight per day of age and gain per day (Fig. 1), and since the former is a simpler calculation, and does not require a birth weight, it appears on the surface to be a practical substitute for the latter.

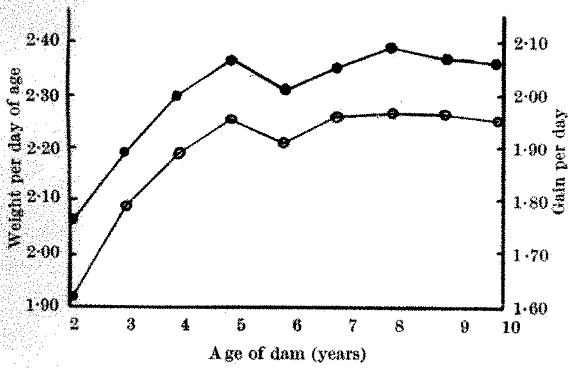

Fig. 1. Correlated change in weight per day of age and gain per day with increasing age of dam in pre-weaning growth period of beef calves. ●, Weight per day of age (lb.); ○, gain per day (lb.)

In 1958 a Canadian technical committee, considering procedures for collecting and summarizing data on beef cattle performance, actually recommended that birth weight be considered as zero in the calculation of growth-rates. This recommendation in effect would substitute weight per day of age for gain per day. Later, in an investigation to determine the magnitude of age of dam effects on pre-weaning growth of beef calves in Canada, the spurious nature of the relationship between weight per day of age and age of calf became clear.

Let us assume that two calves each have a birth weight of 70 lb. One calf is weighed at 120 days of age and is 310 lb., the other is weighed at 250 days of age and weighs 570 lb.

$$\text{Calf 1}\begin{cases}\text{gain per day} = \dfrac{310-70}{120} = 2\cdot00 \text{ lb.}\\[2ex] \text{weight per day of age} = \dfrac{310}{120} = 2\cdot58 \text{ lb.}\end{cases}$$

$$\text{Calf 2}\begin{cases}\text{gain per day} = \dfrac{570-70}{250} = 2\cdot00 \text{ lb.}\\[2ex] \text{weight per day of age} = \dfrac{570}{250} = 2\cdot28 \text{ lb.}\end{cases}$$

These calves are exactly equal in their rates of gain; but calf 1 weighs 0·30 lb. per day more than calf 2. This difference is simply because the birth weight of 70 lb. is spread over only 120 days in calf 1 and therefore contributes 0·58 lb. per day, while in calf 2 it is spread over 250 days and contributes only 0·28 lb. per day. The effect of the 70 lb. of birth weight follows a curve of diminishing effect as the age increases until at 700 days of age it contributes only one-tenth of a pound per day of age and is of no particular practical significance. Even in the post-weaning period, however, it is clear that weight per day of age is not a valid measure of growth.

The spurious negative correlation between weight per day of age and age of calf is clearly evident in data gathered on Hereford calves in the Canadian record of performance programme and is illustrated by Fig. 2.

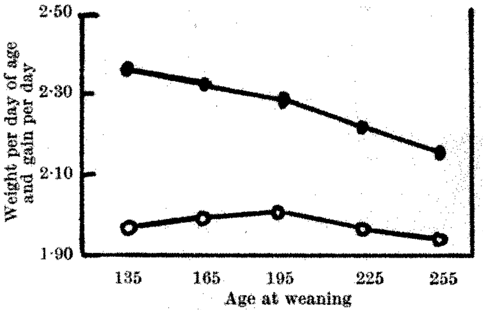

Fig. 2. Relationship between two methods of expressing pre-weaning growth in beef calves as a function of age at weaning. ●, Weight per day of age; ○, gain per day

The lines in Fig. 2 represent the two ways of expressing average growth of the same calves weaned at each age. A total of 5,373 calves are represented. Each sex has been given equal weight in determining each point in Fig. 2. Weight per day of age shows a fairly consistent drop as weaning ages increase while gain per day remains relatively constant.

The negative correlation is masked in Fig. 1 since, within each age of dam class, the average weaning age of the calves is the same within the sampling error and except for any association there may be between weaning age and age of dam.

ENTOMOLOGY

Control of the Ventral Diaphragm in an Insect

The control and origin of heart muscle activity present an unresolved problem in many groups of animals. The hearts of vertebrates and many invertebrates contract myogenically, but rate of beat is controlled by nerve fibres associated with the central nervous system. In the arthropod groups neurogenic hearts have been described in the crustacea and *Limulus*[1], and less completely in some insects[2]; but as pointed out by Beard[3] no general pattern of control and origin of heart-beat has emerged in insects.

Many insects possess in addition to the dorsal heart pumping blood anteriorly a large ventral accessory organ driving the hæmolymph posteriorly and dorsally. In the locust *Schistocerca* this ventral diaphragm extends from the metathorax to near the

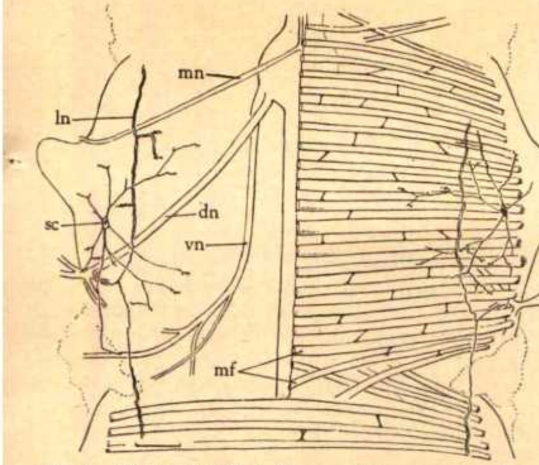

Fig. 1. Greatly simplified diagram of the sternal region of an abdominal segment as seen from above. The ventral diaphragm has been removed on the left side. *dn*, Dorsal nerve; *ln*, lateral nerve; *mf*, muscle fibres; *mn*, median nerve; *sc*, sense cell; *vn*, ventral nerve. Scale, 300μ

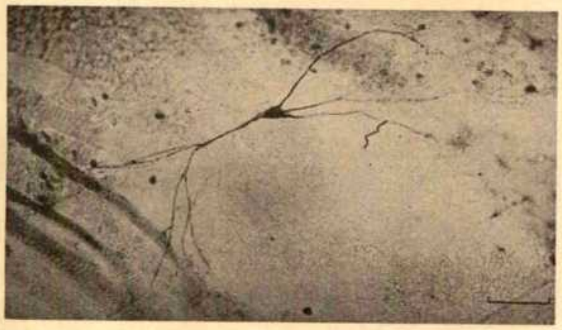

Fig. 2. Sense cell showing processes passing to muscle fibres. Axon process is the uppermost of the left-hand group of processes. Scale, 100μ. *Photograph by D. Warhurst*

extremity of the abdomen, and consists of transverse muscle fibres lying on a connective tissue membrane, stretched across the sternal region of the abdomen. The transverse muscle fibres (Fig. 1, *mf*) are connected by fine anastomoses, and are grouped in fields of 30–40 fibres corresponding to the skeletal segments. At the boundary between these segmental muscle fields oblique muscles overlap the two fields. Each abdominal muscle field contains a pair of sense cells (Fig. 1, *sc*, and Fig. 2) with dendritic endings on the muscle fibres, of a generally similar morphological type to the stretch receptors described by Orlov[4], and Lowenstein and Finlayson[5]. The sense cell terminals end on 15–20 muscle fibres, and there are usually at least three endings on adjacent nerve trunks. The dendrites have flattened leaflet endings (varicose or muff type figured by Orlov). The axon, which is fine and difficult to trace, runs some way posteriorly to join the segmental ventral nerve (Fig. 1, *vn*). The motor fibres have their origin from the segmental dorsal nerve (Fig. 1, *dn*) at the intersegmental level, forming a lateral nerve (Fig. 1, *ln*); this is similar to the paramedian nerve of Schmitt[6]. At least two fibres can be seen in the trunk at most levels, and many muscle fibres can be seen to have endplates contributed to by two fibres. Some at least of these fibres are anterior or posterior rami of single fibres in the dorsal segmental nerves.

The median nerve (Fig. 1, *mn*), which has a spiracular function[7,8], has a connective tissue junction with the lateral nerve, but there appears to be no exchange of fibres.

In the active diaphragm waves of contraction pass posteriorly at the rate of 8–12 waves/min at 18° C; this is normally between a quarter and a fifth of the frequency of beat of the ventilatory muscles in the same preparation. Reversal of beat, a characteristic of invertebrate hearts, sometimes occurs. If the nerve cord is removed, or all the segmental nerves are severed, two changes usually occur in the active diaphragm: first, the rate of beat is about doubled to 20–25/min; secondly, while the segmental muscle fields still contract in series their co-ordination is less regular.

Furthermore, in the intact preparation, light mechanical stimulation of the outer surface of a segment causes rapid twitching of the diaphragmal muscle field of this segment; this is abolished by section of the segmental nerves.

In rather quiescent intact preparations that have been lightly stained the sense cells can be picked out with forceps, and slightly reduced activity is then observable, but this may be due to muscle damage. On the other hand, section of the ventral nerves alone may lead to increased activity and loss of co-ordination.

Division of the active denervated diaphragm across segmental boundaries destroys co-ordination between adjoining fields, which may depend on tension in the oblique muscle fibres. The denervated diaphragm is responsive to direct mechanical stimulation, the fibres going into a state of contracture which may take 10 sec to die away; and to electrical stimulation. Bursts of 25 c/s sawtooth pulses at 0·5-sec intervals will initiate fast rhythmical activity of a similar frequency; much lower or higher frequencies are not effective.

The pattern of afferent and efferent nerve impulses in the segmental nerves is dominated by the rhythm of tracheal ventilation as noted by Hughes[9]. In the motor pathways of the dorsal nerves no very obvious activity is correlated with the slow rhythm of the diaphragm; however, a recording was made from the very delicate lateral nerve (Fig. 1, *ln*) in a rather quiescent preparation (Fig. 3) and this showed a regular discharge in one or perhaps two fibres at about 1/5th-sec intervals; the small value of the spikes, − 0·2 mV, may be partly due to poor contact with the preparation. Records from the ventral nerve cut at the ganglion do show a small group of impulses occurring at intervals of 4 or 5 sec, not present after section of the preparation in the region of the sense cell axon, but it is hoped to make records from the axon itself. One of the main difficulties in making recordings from these preparations is presented by the liveliness of the active preparation.

The evidence summarized suggests that muscular activity in the diaphragm is myogenic in origin and propagated largely by tension. Inhibitory fibres from the ganglia slow the rate of beat, and there are also fast fibres associated with a twitch response. Evidence for a general accelerator fibre has not been

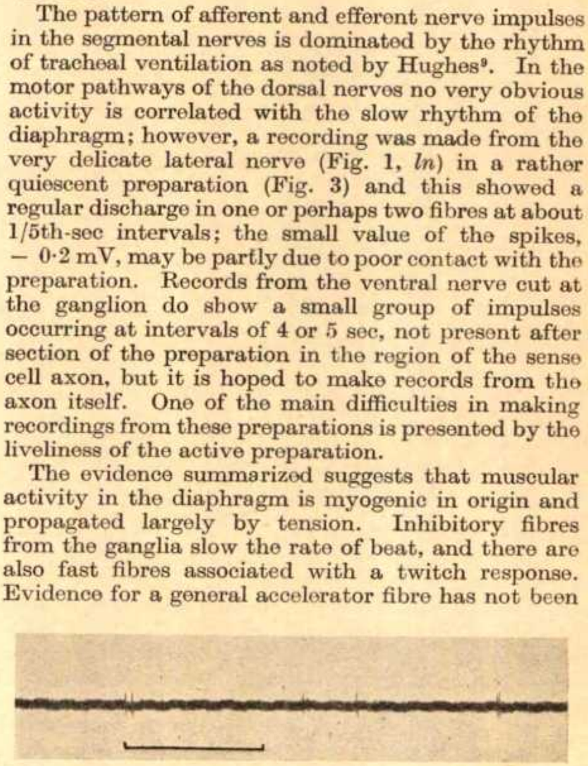

Fig. 3. Recording from the lateral nerve at high amplification. Scale, 0·2 sec

found so far. The function of the sense cell is probably in association with inhibition.

A Case of Dominant Dieldrin Resistance in *Anopheles gambiae* Giles

In the course of field investigations by one of us (J.H.) in the village of Gaoulou near Sassandra, Ivory Coast, a population of *Anopheles gambiae* Giles was found which showed similar low mortalities when exposed to 0·4 and 4·0 per cent dieldrin in 'Risella' oil for 1 h, and high but incomplete mortality when exposed to 4·0 per cent DDT in 'Risella' oil for 1 and 2 h. Detailed results of these exposures as well as results of exposures to the organophosphorus insecticides, malathion and 'Baytex', are given in Table 1.

Table 1. Insecticide Susceptibility of the Gaoulou-Sassandra Population of *Anopheles gambiae*. (Tests made in Africa)

Insecticide (%)	No. of females tested	Exposure period (h)	No. of dead females	Mortality (%)
DDT	Wild caught gravid and freshly fed females			
0	120	1 and 4	5	4
0·5	131	1	13	10
1	156	1	58	37
2	184	1	128	70
4	162	1	147	91
4	108	2	104	96
4	116	4	116	100
Dieldrin	Wild caught gravid and freshly fed females			
0	21	1	1	4
0·4	112	1	13	12
4	116	1	10	9
Malathion	Laboratory bred females, freshly fed			
0	100	1	3	3
0·4	81	1	2	2
0·8	101	1	18	18
1·6	99	1	86	87
3·2	79	1	79	100
Baytex	Laboratory bred females, freshly fed			
0	Same controls used as for malathion			
0·2	38	1	1	3
0·4	99	1	21	21
0·8	118	1	97	82
1·6	80	1	80	100

In May 1962 eggs from this population were dispatched to the Ross Institute in London, where a colony was successfully established. The results of testing the susceptibility of adults reared from these eggs and of adults of the first laboratory generation on DDT and dieldrin are given in Table 2. Similar low and almost identical mortalities are shown on 0·4 and 4·0 per cent dieldrin for 1 h, and these are very similar to the mortalities found in the field. On 4·0 per cent DDT for 1 h, however, no survivors were found in London. It is concluded that the increased tolerance to this insecticide in the field is the result of a slight 'vigour tolerance' and not to the presence of individuals specifically resistant to DDT.

Table 2. Insecticide Susceptibility of the Gaoulou-Sassandra Population of *Anopheles gambiae*. (Tests made in London on Laboratory-reared, Unfed Females and Males, 1–4 days old)

Insecticide (%)	No. of mosquitoes tested	Exposure period (h)	No. of dead mosquitoes	Mortality (%)
0	35	1	1	3
0	39	5	0	0
DDT				
4·0	289	1	289	100
Dieldrin				
0·4	97	1	13	13
4·0	104	1	11	11
4·0	137	5	54	39

Females of the Sassandra colony have been crossed with males of an insecticide-susceptible strain of *A. gambiae* from Diggi, Western Sokoto, Northern Nigeria, and with a homozygous dieldrin-resistant strain from Kano, Northern Nigeria. These belong to the two partially incompatible fresh-water forms of *A. gambiae* described by Davidson and Jackson[1]—Diggi to the group *A* and Kano to the group *B*. F_1 males of the Kano × Sassandra cross were sterile while those from the Diggi × Sassandra cross were normal. The Sassandra strain thus belongs to group *A*.

The results of testing the F_1 and F_2 generations of the Diggi × Sassandra cross on 0·4 and 4·0 per cent dieldrin for 1 h are given in Table 3. The F_1 adults show no mortality on either dosage, while the F_2 adults show a similar mortality on both dosages, and this mortality is very close to 25 per cent. It is concluded, therefore, that the Sassandra females used on this cross were homozygous for dieldrin resistance, and that resistance in this strain is dependent on a single dominant genetic factor.

Table 3. Mortalities on Dieldrin of F_1 and F_2 Generations of Cross, Diggi ♂ × Gaoulou-Sassandra ♀. (Tests made in London on Laboratory-reared, Unfed Females and Males, 1–4 days old)

Dieldrin (%)	No. of mosquitoes tested	Exposure period (h)	No. of dead mosquitoes	Mortality (%)
		F_1 generation		
0·4	7	1	0	0
4·0	51	1	0	0
		F_2 generation		
0	39	1	0	0
0·4	530	1	118	22
4·0	545	1	145	27

In respect of its dominance this type of resistance differs from those previously recorded for three other strains of *A. gambiae* from West Africa and for other anopheline species[2]. Here dieldrin resistance was found to be monofactorial and semi-dominant, 0·4 and 4·0 per cent dieldrin for 1 h being the dosages discriminating between susceptible, heterozygotes and resistant individuals.

MICROBIOLOGY

Production of a Gibberellin-like Substance by *Arthrobacter globiformis*

The ability to synthesize plant growth substances such as indolyl-3-acetic acid (IAA) is widely distributed among micro-organisms. But the production of gibberellins appears to be much more restricted, fungi of the genus *Gibberella* being the chief microbial source. However, in recent work on IAA production by species of *Arthrobacter*[1] we detected another growth-promoting zone on chromatograms of culture filtrates by means of a modified *Avena* coleoptile section test. These observations along with a report of gibberellic acid production by *Azotobacter*[2] prompted further work on the synthesis of gibberellin-like substances by *Arthrobacter*.

Arthrobacter globiformis (415), the type species of this genus, was grown in a synthetic medium containing per litre distilled water, sucrose, 10 g; KNO_3, 0·5 g; biotin, 10 μg; salt solutions *A* and *B* (ref. 3), 5 ml. each; *p*H 6·8–7·0. The culture was grown at 26° C on a rotary shaker for varying periods of time and the cells removed by centrifugation. The cell-free culture medium was stirred with 50 g/l. of cellulose and carbon (4 : 1) for 2 h and the mixture filtered. The aqueous fraction was discarded. The residue was washed with 95 per cent acetone, using 1/3 of the volume of the original culture medium, the eluate evaporated under reduced pressure, taken up in water and, after *p*H adjustment to 3·0, extracted with ether and/or ethyl acetate. The extract was concentrated under reduced pressure, chromatographed and segments of the chromatogram or eluates of these assayed at different time intervals for growth-promoting activity by means of a modified *Avena* coleoptile section test.

Three solvent systems were used for chromatography: (*a*) isopropanol/ammonia/water (8 : 1 : 1); (*b*) *n*-butanol/acetic acid/water (4 : 1 : 1); (*c*) ethanol/ammonia/water (18 : 1 : 1). Extracts enriched with authentic IAA and gibberellic acid at levels sufficient for colour detection were chromatographed in addition to the extracts alone. In one-way chromatography with the three solvents and in two-way chromatography with solvents (*a*) and (*b*) a growth-promoting substance which co-chromatographed with gibberellic acid was detected consistently. In all instances, unlike IAA, and like gibberellic acid, the substance did not produce curvature of coleoptile segments; furthermore, depending on the degree of purification, the time-activity curve was similar to that of gibberellic acid. Since the chromatographic and biological behaviour of the substance suggested gibberellic-like activity other tests accepted as more or less specific for gibberellic acid were performed with eluates of the gibberellic acid zones of the chromatograms: the lettuce seed germination test of Cathey *et al.*[4], the lettuce hypocotyl test of Frankland and Wareing[5] and the dwarf pea test of Brian and Hemming[6]. Typical results are shown in Table 1; whereas the substance has no significant activity in the pea test, the increase in per cent germination and the elongation of the hypocotyls as well as the activity detected by means of the *Avena* coleoptile test all suggest that it can be considered a gibberellin. The characterization of this substance is in progress.

Unlike *Azotobacter*, members of the genus *Arthrobacter* occur in large numbers in most soils. Rouatt and Katznelson[7] have reported that 45 per cent of the isolates from soil extract agar plates of root-free soil and 34 per cent of those from wheat rhizosphere soil representing respectively 54 × 10^6 and 240 × 10^6 organisms per gram soil were of this genus. In consequence, significant amounts of biologically active substances may be produced with corresponding effects on seed germination, root development and possibly on mineral nutrition of plants[8]. These effects may be even more striking under conditions favouring the production of precursors of these substances as in the case of tryptophan for IAA synthesis[1,9].

Table 1. PRODUCTION OF A GIBBERELLIN-LIKE SUBSTANCE BY *Arthrobacter globiformis*

Test used	Gibberellin acid μg/ml. buffer*				Extract ml. equiv. original culture/ml. buffer*				Control
	0·01	0·1	0·5	5·0	1·0	5·0	10·0	20·0	
Lettuce seed germination (per cent)		30	35	45	30	45		30	20
Lettuce hypocotyl elongation (mm)	13	19				14	13		9
Dwarf pea internode elongation (mm)	15	24			9	9	9	10	8

PSYCHOLOGY

Detection of Cosmic Ray μ-Mesons by the Human Eye

THE detection of ultra-violet light and X-rays in the human eye, through a fluorescence mechanism, is well known[1], and it would be expected that a high flux of ionizing particles would be similarly detectable. There is apparently no record in the literature of the detection of single minimum ionizing particles, though there are several mechanisms by which a relativistic particle may release a detectable amount of energy in traversing the eye. These include the emission of Čerenkov radiation[2] in the vitreous humour. An ultra-relativistic singly-charged particle, in median passage through a normal eye, from lens to retina, generates approximately 600 photons in the visible, which will be collected over a large part of the retinal area. The visual signal would be equivalent to that from an illuminated disk, with intensity increasing from about 0·5 photon/mm^2 at the periphery to about 10 photons/mm^2 at the centre. This light is emitted essentially instantaneously (within 10^{-10} sec) and has an intensity comparable with that at the threshold of vision[3]. In addition to Čerenkov radiation, light may be released by scintillation in the crystalline lens or vitreous humour, or direct excitation of the retina may occur.

Preliminary tests have been carried out with a number of observers, to verify this possibility. The observer lay on a couch in a dark room, and a small Geiger telescope was attached to a pair of darkened goggles worn on the head, so that cosmic ray μ-mesons, passing through the right eye within 15° of the vertical, were selected. The telescope operated a mechanical register which was audible to the observer,

Table 1

	Genuine counts				Spurious counts				
Observer	Total	Yes	No	Yes/total	Total	Yes	No	Yes/total	P
1	18	6	12	0·33	112	19	93	0·17	0·10
2	23	3	20	0·13	233	20	213	0·09	0·35
3	59	12	47	0·20	190	28	162	0·15	0·17
4	34	11	23	0·32	213	40	173	0·19	0·06
5	33	15	18	0·46	157	47	110	0·30	0·08
6	26	3	23	0·12	152	21	131	0·14	0·70
7	20	2	18	0·10	179	8	171	0·04	0·23
8	30	3	27	0·10	196	15	181	0·08	0·40
9	31	10	21	0·32	181	49	132	0·27	0·35
All observers	274	65	209	0·237 ± 0·029	1,613	247	1,366	0·153 ± 0·010	

and a scaler. Mesons were counted at a rate of approximately 1/min. A somewhat larger Geiger telescope placed some distance away, operating at about 5 counts/min, was connected to the same mechanical register, but to a different scaler. Thus identical audible signals were given to the observer at random intervals, and only 20 per cent of these corresponded to the passage of a genuine μ-meson through the eye. The scaler readings were recorded by an operator in communication with the observer. The observer answered 'yes' or 'no' to each signal, and the results were analysed, to look for a higher proportion of affirmative responses in the case of the genuine events. Nine observers were tested. A period of dark adaptation was allowed before commencing observations. Operation was possible for a period of about 30–45 min, after which fatigue and discomfort due to the goggles became serious. The results are summarized in Table 1.

P is the Poisson probability for each observer that the observed or a greater number of counts should be found in the genuine channel, when the expectation number is derived from the spurious channel. Eight of the nine observers recorded a higher proportion of affirmative responses for genuine signals than for spurious, but none is individually significant. The total results summed for all observers do, however, appear to indicate a significant effect, at about the 0·4 per cent level, assuming the ratios to be distributed normally. The effect of summation is to reduce the significance-level of the results, but since the numbers of genuine events were small for individual observers, the use of χ^2 was not considered legitimate. The signal detected may not in fact be due to Čerenkov radiation; observers described the visual sensation associated with the genuine signals as a bright point of light, rather than the diffuse disk expected, and it is possible that the detection is through a direct excitation of the retina. The energy deposited by ionization in traversing a rod or cone is about 500 eV.

Immediate Detection of X-rays by the Rat

Recently we postulated that mammals perceive radiation and have commenced an investigation of its perceptual aspects and its underlying physiological receptor mechanism. Small doses of radiation (10–20 r.) have been used as a noxious stimulus to establish avoidance reactions in blind and normal laboratory animals under a wide variety of experimental conditions[1–4]. While these experiments indicate that animals perceive radiation, they afford no measure of the reaction time of the animal to the onset of the radiation exposure. We are now measuring this important parameter in rats by using X-rays as a warning stimulus to signal the occurrence of a subsequent electric shock to the animal's paws.

The animals are tested and trained in a standard instrumental conditioning apparatus which consists of a small acoustically treated compartment equipped as follows: A lever, operated by the rat, actuates a mechanism adjusted to deliver a pellet of food for every twelve responses. The response-rate is recorded by a cumulative response recorder. The compartment floor is an electric shocking grid and a speaker provides a continuous wide-band noise to mask extraneous sounds. Behaviour can be observed visually through a double pane window.

The compartment is situated directly under an X-ray therapy machine with factors of 250 kV, 0·5 mm copper filter, 1·7 copper, half-value layer. Output is measured by a 'Victoreen' chamber lying in the animal's compartment, hence includes back scatter. A plate of 3/16 in. lead suspended between the X-ray tube and the animal's compartment can be moved inaudibly to expose the animal while the machine remains in continuous operation. As a precaution, sham exposures are alternated with actual exposures under identical procedures except that the copper filter in the X-ray machine is replaced by a lead plate which effectively blocks the X-ray at its source.

Training is a variation of the Estes–Skinner conditioned-suppression technique[5]. As a preliminary procedure the lever is removed from the compartment while the animal is conditioned with radiation and electric shock. In a typical case this training consisted of a 10-sec X-ray with intermittent shock during the last 8 sec of exposure. Ten exposures were administered at irregular intervals (1–3 min). This was repeated every 2 or 3 days until 40 conditioning exposures were administered.

Testing is conducted while the animal is actively pressing the lever for food. The suspended shield is moved and the animal is exposed without the subsequent electric shock. In many cases this brief exposure causes an immediate arrest in the animal's lever pressing behaviour. Fig. 1 is a sample of the cumulative response records of two animals trained and tested with a 10-sec exposure at 1·0 r./sec (rat A) and a 15-sec exposure at 0·2 r./sec (rat B). The horizontal step in the slope of the record indicates that the rats ceased to press at the onset of the shock-free exposure and resumed activity immediately after the exposure was terminated. Since sham exposures did not suppress the response it is apparent that the X-ray is the critical stimulus.

Other animals did not exhibit conditioned suppression in the first tests and were subjected to the following procedure. If a rat pressed the lever during exposure, the response was considered an error and he was given an electric shock. Lever pressing between exposures were rewarded as in the previous training. Each animal was trained until he performed five consecutive errorless, hence shock-free, trials, or received a maximum of twenty trials. The mean performance of four rats exposed to 10-sec X-ray at 1·0 r./sec is given in Fig. 2. Errors, that is, lever pressing during exposure, decline with increased training much as one would expect with discrimination training with stimuli such as visible light or sound stimuli. During the sham exposures the animals continued to press the lever as indicated by the dotted line (Fig. 2). All the animals (12) trained in this manner exhibited repeated conditioned suppressions during shock-free exposures within 10 trials.

While this procedure is often referred to as discrimination training, it is apparent that the animal can perceive X-rays before the training begins. During our efforts to habituate animals to the X-ray room we observed that animals tended to go to sleep during sham exposures and to remain awake during actual exposures. Furthermore, after a few treatments with X-ray and electric shock during preliminary training many animals attempted to escape from the compartment at the onset of X-ray, indicating that defensive responses to shock had quickly been conditioned to radiation. Subsequent training to inhibit the lever pressing response during exposure serves to provide objective evidence of the animal's ability to detect the presence of X-rays.

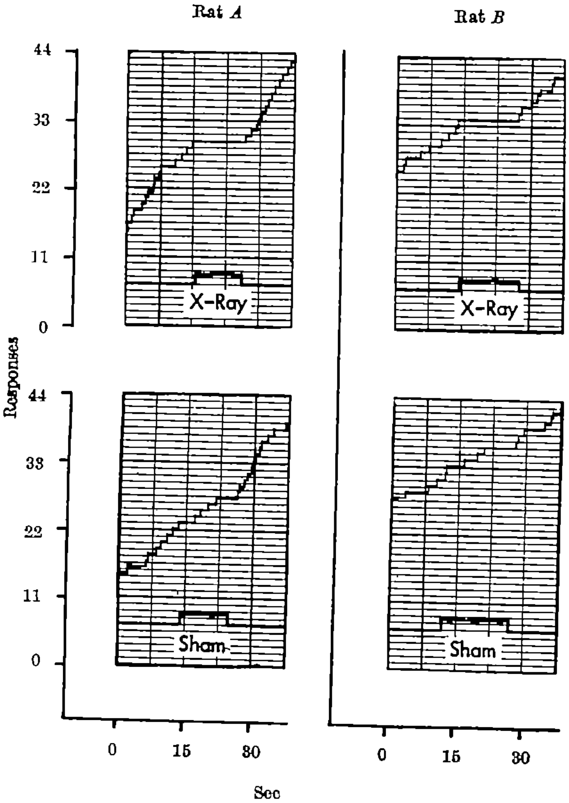

Fig. 1. Conditioned suppression of lever pressing response in rats with X-ray. Rat *A* was tested with 10-sec exposure at 1·0 r./sec and rat *B* with 15 sec at 0·2 r./sec. In prior conditioning X-ray had served as a warning stimulus for electric shock. No shock was used during these tests

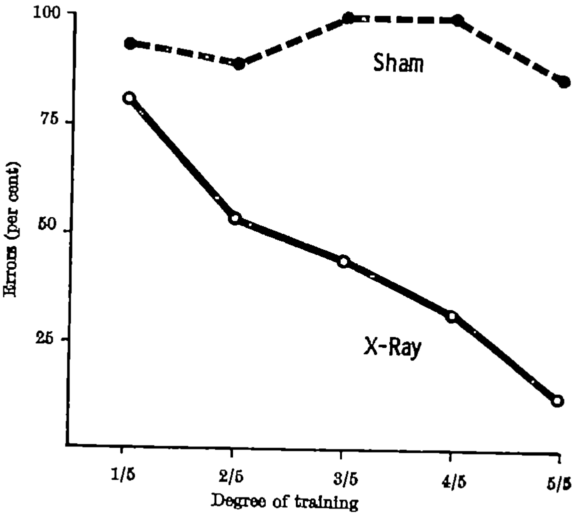

Fig. 2. Mean performance of four rats during discrimination training with 10-sec X-ray exposure (1·0 r./sec). Errors, that is, responses during exposure, were followed by shock. Responses during sham exposure led to food. Training is plotted in successive fifths of total trials received by each animal. Criteria was five consecutive errorless (shock-free) trials with maximum of 20 trials

Preliminary experiments indicate the ophthalmectomized animals can also detect X-rays, thus phosphenes or other visual effects cannot account for the phenomena. Our present evidence indicates a receptor system of extremely fast reaction time and great sensitivity. Animals can detect the very onset of a dose-rate of 0·2 r./sec. Experiments with lower doses are in progress. (*Note added in proof.* Experiments conducted since submission of this report indicate dose-rates of 0·05 r./sec or less are effective.)

COSMOLOGY

Transfinite Numbers and Cosmology

A COMPLETE analysis of Dr. Schlegel's communication on this subject[1] would take too long: but some correction should be made.

In Dr. Schlegel's equation:

$$N = N_0 e^{kt} \qquad (1)$$

t is finite. The equation is only an idealized approximation: it would be better enunciated for the large but finite number N_0 of atoms in a large but finite initial volume V_0: for all that, the equation is not objectionable. But the substitution of an infinity for t is objectionable. The infinity to which t tends is not $\aleph_0$. In Dr. Schlegel's formula :

$$N \geqslant e^{\aleph_0} \qquad (2)$$

the right-hand side is meaningless: and the argument does not yield:

$$N \geqslant 2^{\aleph_0}$$

as Dr. Schlegel claims. It yields only that $N \geqslant K$ for any finite integer K, that is:

$$N \geqslant \aleph_0 \qquad (A)$$

The hypotheses involved here are that the universe is expanding, and that it looks the same everywhere at all times.

To obtain the opposite inequality:

$$N \leqslant \aleph_0 \qquad (B)$$

one is much less committed. Irrelevant are all questions of isometric embedding: relevant only is the question whether the universe can be exhausted by a countable set of small neighbourhoods: this is in essence the question whether the universe is 'separable'. There exist (in the mathematical sense) topological manifolds which are not separable, but that sort of thing is excluded by the assumption of a global metric: it is a familiar fact that any Riemannian manifold is separable. Even if we abandon the hypothesis of a Riemannian metric in some quantized theory, it can scarcely be doubted that (B) would still follow from the steady-state hypothesis, in any event if this included some hypothesis of isotropy.

On the usual interpretation of the red shift we can have no future physical connexion with atoms beyond a certain finite distance. This leads to a difficulty about the derivation of (B) which may trouble some. Do such atoms 'exist'? How can they be 'counted'? Such questions invite confusion between conceptual existence (on one of the steady-state-expanding-universe concepts) and physical-existence-for-us: and doubt may easily result. But the universe consists of those atoms, and parts of space, which are connected with us not necessarily by one such physical connexion but by a finite chain of such physical connexions as are envisaged (reception and transmission of signals). This gives a closed system: to conceive the 'existence' of any further atoms is to indulge in idle fantasy: this closed system is the universe: and it is separable.

H. D. URSELL

Department of Mathematics,
University of Leeds.

[1] *Nature*, 193, 665 (1962).

THE application of transfinite numbers to physical theory is admittedly novel, and should be open for critical discussion; none the less, I see no force in the arguments which Mr. Ursell presents.

In my communication I implicitly made use of the accepted relation $2^{\aleph_0} = n^{\aleph_0} = C$, where n is any integer greater than 1 and C is the power of the continuum, and on the basis of this relation I set $e^{\aleph_0} = C$. It is true that $e^{\aleph_0}$ has not been defined in transfinite-number theory; we may, however, readily come to the non-denumerability of atom-spaces, in steady-state theory, without making use of this quantity. The growth equation $N = N_0 e^{kt}$ requires $N/N_0 = 2$ for a time-interval $t_2 = (1/k)\log 2$. It follows, then, that any chosen finite set of atom-spaces will be doubled in time t_2. Indeed, over-looking fluctuations in the presumed creation process, we can say that in time t_2 each atom-space becomes two atom-spaces. Hence, each atom-space in a given set becomes two atom-spaces in an interval t_2. Since, by hypothesis, the universe has existed for a time $\aleph_0$, and $\aleph_0 \cdot t_2 = \aleph_0$ (we may choose time units so as to make t_2 an integer), we have a set of $\aleph_0$ factors of 2. Hence, a set of atom-spaces with cardinal number $2^{\aleph_0} = C$ must have been formed in the universe. We could equally well have worked with a t_n, defined for an n-fold increase of any finite group of atoms, with the same result: there is a set of atom-spaces with cardinal number $n^{\aleph_0} = C$.

It is a basic tenet of steady-state theory that the universe has always existed with its present large-scale features. I take this to mean that the universe has existed for an achieved infinity of years: a set of years with the cardinal number $\aleph_0$. The alternative assumption is that the life-time of the universe is t years, where t 'tends to infinity', that is, is indefinitely large, but is still a finite number. This assumption would not give the universe the steady-state property of having existed for ever.

Mr. Ursell proposes that cosmological considerations must be limited to those parts of the universe with which physical interaction, as through signal chains, is possible. Such interaction is a factor of doubtful relevance in the consideration of the consistency properties of cosmological models (as opposed, of course, to matters of empirical confirmation). In any event, he presents no argument that would allow a set of C atom-spaces to be fitted into a universe which everywhere has the spatial properties (in accordance with the cosmological principle used in steady-state theory) that we find in our observed universe.

RICHARD SCHLEGEL

Department of Physics,
Michigan State University,
East Lansing, Michigan.

THE force of my arguments must, it seems, be a matter of opinion. Dr. Schlegel "may readily come" to various conclusions, but mostly without me.

Dr. Schlegel's central fallacy, on my evaluation, lies in the easy substitution of an infinity for a finite number in a formula. This is how he leaves the slippery slope of ambiguities for the abyss: this is where I do not follow. In the foregoing communication the error is implicit in his phrase, "set of $\aleph_0$ factors", explicit in the next sentence. I concede a factor of 2^n between the year n B.C. and now: I do not concede his factor of $2^{\aleph_0}$ between, presumably, the cold bleak world of $\aleph_0$ B.C. and now.

Dr. Schlegel's objection to my final paragraph is disheartening. I am there defending, against some quite possible criticism, the statement (B) above which he himself made (ref. 1, p. 666, line 12). Even when I agree with him, he disagrees with me.

H. D. URSELL

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, December 10

Institution of Mechanical Engineers, Manipulative and Mechanical Handling Machinery Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Universal Excavators *versus* the Front End Loader".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Sir John Hunt, C.B.E., D.S.O.: "A British–Russian Expedition to the Pamirs".

Monday, December 10—Tuesday, December 11

Powder Metallurgy Joint Group of the Iron and Steel Institute and the Institute of Metals (at Church House, Great Smith Street, London, S.W.1), at 11.15 a.m. on Monday and 10 a.m. on Tuesday—Winter Meeting.

Tuesday, December 11

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.

Institution of Electrical Engineers, Science and General Division (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. A. G. Heaton: "Thermoelectrical Engineering".

Institution of the Rubber Industry (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. C. Musgrave: "Colouring of Rubber". 7 p.m.—Panel Discussion on "Rubber *versus* Plastic in Footwear".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. D. Richter. "Brain Biochemistry in Relation to Psychiatric Disorders"*. (Seventeenth of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

Institution of Mechanical Engineers, Automobile Division (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. D. K. MacKenzie, Mr. T. P. Newcomb and Mr. B. D. Watton: "Car Brake Usage Test Schedules".

Wednesday, December 12

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Dr. H. Harris: "Inborn Errors of Metabolism".*

Colour Group (Great Britain) (in Lecture Theatre No. 2 of the New Physics Department, Imperial College, London, S.W.7), at 3 p.m.—Dr. F. J. J. Clarke: "Further Studies of Extra-Foveal Colour Metrics". 4 p.m.—Dr. W. A. H. Rushton: "Visual Adaptation".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. A. H. Strude: "Current-swept Sea-floors near the Southern Half of Great Britain"; Dr. F. Howitt: "Stratigraphy and Structure of the Purbeck Inliers of Sussex".

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.15 p.m.—Mr. C. D. Foster and Dr. M. E. Beesley: "Estimating the Social Benefit and Loss from Investing in the Victoria Line".

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. J. A. Saxton: "Radio Meteorology".

British Institution of Radio Engineers, Education Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Discussion on "Teaching Mathematics to Engineers".

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. F. H. S. Brown: "Duty and Development of Modern Power Station Plant" (Parsons Memorial Lecture).

Royal Institute of Chemistry, London Section (at Shell-Mex House, Strand, London, W.C.2), at 6 p.m.—Annual General Meeting, followed by Mr. George Dring, "Qualifications in Chemistry".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. Brian Parkyn: "Glass Fibre Reinforced Plastics".

Society of Environmental Engineers (in the Mechanical Engineering Department, Imperial College, London, S.W.7), at 6 p.m.—Mr. A. P. Longmore: "Simulation of a Space Environment".

Institute of Information Scientists (at the Swedenborg Society Hall, 20 Bloomsbury Way, London, W.C.1), at 6.15 p.m.—Dr. A. R. Meetham: "Mechanical Indexing".*

Society of Chemical Industry, Food Group (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Mr. J. A. O'Keefe and Dr. Magnus Pyke: "Nutrition and the Law".

Society for Analytical Chemistry, Atomic Absorption Spectroscopy Discussion Panel (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Inaugural Meeting—Mr. D. J. David: "Aspects on Atomic Absorption Analysis".

Society of Instrument Technology, Control Technology Section (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. D. H. A. Harvey and Mr. G. S. Kardoosh: "Hot Strip Rolling Mill Looper Control"; Mr. A. F. Watters: "Position Control of a 150-Ton Forging Crane".

Wednesday, December 12—Thursday, December 13

Association for the Study of Animal Behaviour (at Birkbeck College, Malet Street, London, W.C.1), at 11 a.m. on Wednesday and 10 a.m. on Thursday—Symposium on "Gregarious Behaviour".

Thursday, December 13

Institution of Electrical Engineers, Power Division (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. F. Brailsford and Dr. V. R. Mazza: "An Experimental Investigation into the Alternating Magnetic Flux Distribution in Right-Angled Corners of Transformer Laminations".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. J. N. P. Davies. "Cancer in the Tropics, with special reference to Neoplasms in Childhood".* (Last of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 6 p.m.—Scientific Papers.

Prestressed Concrete Development Group (at the Royal Institute of British Architects, 66 Portland Place, London, W.1), at 6 p.m.—Mr. Felix Adler. "Prestressed Concrete in Building".

Association of Supervising Electrical Engineers (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 6.15 p.m.—Mr. L. Landon Goodman: "The Electrical Engineer's Contribution to Productivity".

Society for Analytical Chemistry, Biological Methods Group (in the "Feathers Restaurant", Tudor Street, London, E.C.4), at 6.30 p.m.—Eighteenth Annual General Meeting, followed by Dr. A. J. Amos: "The Assessment of Vitamins in Feeding Stuffs".

Institute of Metals (joint meeting with the London Branch of the Institute of British Foundrymen, at the Institute of Metals, 17 Belgrave Square, London, S.W.1), at 7 p.m.—Mr. R. E. Berry: "Trends on Non-Ferrous Melting Practice".

Radar and Electronics Association (at the Royal Society of Arts, John Adam Street, London, W.C.2), at 7 p.m.—Mr. R. A. Turrell and Mr. B. J. Rogers: "Colour Television Services".

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Symposium on "Medical Problems Presented by the Tristan da Cunha Community". Speakers: Dr. H. E. Lewis, Dr. C. K. Thacker, Dr. D. Taylor-Robinson, Dr. D. A. J. Tyrrell and Prof. A. Sorsby.

Friday, December 14

Biochemical Society (in the Department of Chemistry, Westfield College, Hampstead, London, N.W.3), at 9.30 a.m.—Colloquium on "The Organic Chemist's Approach to Enzymology" and original communications.

Society of Non-Destructive Examination (at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 3.30 p.m.—Dr. R. Jones. "The Uses of Ultrasonics".

Institute of Navigation (at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1), at 5.30 p.m.—Capitaine de Frégate L. Oudet: "Routing in the Dover Strait".

Society for Analytical Chemistry, Microchemistry Group (joint meeting with the Midlands Section, at the University, Edgbaston, Birmingham), at 6.30 p.m.—Dr. A. M. G. Macdonald: "The Determination of Carbon and Hydrogen in Organic Materials".

Friday, December 14—Saturday, December 15

Committee of Vice-Chancellors and Principals of the Universities of the United Kingdom (in the William Beveridge Hall, University of London Senate House, London, W.C.1), at 2.30 p.m. on Friday and 10.30 a.m. on Saturday—Home Universities' Conference.

Monday, December 17

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Mr. R. H. Hughes: "Hong Kong—Far Eastern Meeting Point".

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. H. E. M. Barlow, F.R.S.: "A Proposed New Method of Measuring Microwave Power and Impedance using Hall Effect in a Semiconductor"; "High-Frequency Radiation Pressure and Hall Effect in Semiconductors"; "A Microwave Electrostatic Wattmeter".

Institute of Metal Finishing (at the Northampton College of Technology, St. John Street, London, E.C.1), at 6.15 p.m.—Mr. J. Carder: "Satin Nickel + Chromium Plating".

Monday, December 17—Tuesday, December 18

Association of Applied Biologists (in the Physics Department, Imperial College of Science and Technology, London, S.W.7), at 2.30 p.m. on Monday, and 10.30 a.m. on Tuesday—General Meeting.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer or Senior Lecturer (qualified to supervise post-graduate studies and research in functional analysis) in Pure Mathematics—The Registrar and Secretary King's College, (University of Durham), Newcastle upon Tyne (December 15).

Research Assistant (with good qualifications in chemistry or physiology), to work on biochemical effects of radiation—The Personnel Officer, St. Bartholomew's Hospital, London, E.C.1 (December 15).

Plant Physiologists, Microbiologists and Biochemists, for work involving fundamental research (with ample scope for original work and its publication)—The Director, Brewing Industry Research Foundation, Nutfield, Surrey (December 17).

Assistant Lecturer in Pure Mathematics—The Secretary, The University, Northcote House, The Queen's Drive, Exeter, Devon (December 31).

Chair of Applied Chemistry in the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 31).

Senior Lecturer in Mathematics at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 31).

Senior Lecturer or Lecturer (with special qualifications in plant physiology and preferably the ability to conduct an elementary course in plant genetics) in the Department of Botany, University of the Witwatersrand, Johannesburg—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, December 31).

Chair of Clinical Ophthalmology at the Institute of Ophthalmology—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 2).

Sembal Chair of Experimental Ophthalmology at the Institute of Ophthalmology—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 2).

Lecturers (2) (qualifications in analysis will be relevant for one post) in Mathematics—The Secretary, The University, Aberdeen (January 8).

Chair of Philosophy—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (January 5).

Lecturer (man or woman) in Botany—The Principal, Royal Holloway College (University of London), Englefield Green, Surrey (January 7).

Senior Lecturer in Geophysics at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, January 7).

Senior Lecturer or Lecturer (with experience in the fields of inorganic and/or physical chemistry) in Chemistry at the Australian National University—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 7).

Lecturer (especially interested and qualified in the field of structural geology) in Geology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 10).

Senior Fellow, Fellow, or Senior Research Fellow in a Unit of Cell Biology and Immunology within the Department of Experimental Pathology, The John Curtin School of Medical Research, Australian National University, to engage in studies on acquired immunity and on mechanisms involved in the responses and interactions of cells—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London. S.W.1 (Australia and London, January 11).

Jubilee Research Fellow (woman graduate of any nationality), for research in any subject within the Faculties of Arts or Science—The Principal, Royal Holloway College (University of London), Englefield Green, Surrey (January 14).

Lecturers/Senior Lecturers (2) in Biochemistry at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 31).

Assistant Lecturer (with qualifications (1) in any branch of pure mathematics, (2) in numerical analysis or statistics) in the Department of Mathematics—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff.

Junior Scientific Assistant (with training in either genetics or microbiology and preferably with some knowledge of both) for mutation research on *Neurospora*—Dr. Charlotte Auerbach, F.R.S., Institute of Animal Genetics, West Mains Road, Edinburgh.

Postdoctoral Research Assistant, for work on nuclear magnetic double resonance techniques—Dr. D. W. Turner, Chemistry Department, Imperial College of Science and Technology, London, S.W.7.

Senior Research Assistant, to join a team doing research in high pressure chemistry, with some applications to geochemistry——Dr. R. S. Bradley, Department of Inorganic and Structural Chemistry, The University, Leeds 2.

THE NATIONAL LENDING LIBRARY FOR SCIENCE AND TECHNOLOGY

THE official opening of the new National Lending Library for Science and Technology on November 5 (see also p. 1034 of this issue) was properly an occasion for the Department of Scientific and Industrial Research, and it was appropriate that the opening ceremony should be performed by Lord Hailsham, both as Minister for Science and Lord President of the Council, to whom the Council for Scientific and Industrial Research is responsible. Nevertheless, while both the Chairman and the Secretary of that Council were present, the platform party included no representative of the Advisory Council on Scientific Policy, although, as Lord Hailsham indicated, it was by that body that the creation of a new national science lending library was recommended some ten years ago. The Advisory Council had earlier, in 1951, recommended the establishment of the National Reference Library of Science and Invention and has steadfastly advocated both projects since after almost a decade of wavering and indecision the Government finally rejected the imaginative conception of a Science Centre in London. It is true that, as Sir Harold Roxbee Cox remarked at the opening ceremony, the Council for Scientific and Industrial Research is now charged with some specific responsibility for the dissemination of scientific literature, and that the by return of post lending service, the rapid copying service, the translation service and the training schemes at which the new Library aims, go far beyond anything contemplated in the Science Centre, but nevertheless it is fitting that the part played by the Advisory Council on Scientific Policy and the wide responsibilities of the Council in this field should be recognized at the inauguration of this important project.

The location of the new Lending Library and some features of its planning and staffing have naturally not escaped criticism, but this is no occasion for other than congratulations to the director of the Library, Dr. D. J. Urquhart, and to all concerned. Dr. Urquhart was able on this opening day to show an operating establishment which in planning and equipment makes full use of the remarkable advances in scientific technique in this field during the past two decades. He has had the courage to break imaginatively with many current library techniques and practices, and although it is as reasonable to wait for experience to attest the soundness of his judgment at all points as it would be unreasonable to expect a new venture to be entirely free from teething troubles, it was clear to all that the claim was fully justified that here was something unique in Great Britain. Moreover, what may fairly be described as the most outstanding development in libraries in Britain during the past decade or more and a valuable contribution to more effective communication between science and industry is already staffed by those whose keenness and enthusiasm was as obvious as it was refreshing to the visitor.

Here there is already an achievement which reflects the highest credit on all responsible and for which the scientist and technologist has every reason to be grateful. That gratitude should, however, as Dr. Urquhart has already indicated, and Lord Hailsham repeated, be expressed, at least in part, in co-operation and in support. Important as it is, the new National Lending Library for Science and Technology is, as its name implies, only one element in a national library system. Its full possibilities and efficiency will only be realized in the context of a national system, and its inauguration should give further impetus to the establishment of the National Reference Library for Science and Invention, still at the planning stage.

It may well be true that the implementation of the conception of a Science Centre in London on the lines which Sir Robert Robinson so untiringly advocated offered the maximum economy of national resources, but it is none the less open to doubt whether in such a setting a National Lending Library could have possessed anything like the spaciousness that has given Dr. Urquhart his opportunity for such imaginative design and break with traditional practice. Here, however, new techniques and developments have been fully utilized, but the benefits will be reaped largely as local libraries respond to Dr. Urquhart's appeal for co-operation, for example, in regard to improving their holdings of abstract publications. Other libraries, too, must take a forward look and endeavour to meet the needs of the future by adopting new techniques and discarding, where possible, techniques that are obsolete as well as traditional.

Nor is this all. No institution like the new Library is likely to flourish without constructive criticism, but such criticism must be inspired by clear ideas of what functions the institution is intended to perform. It is also essential that the institution should be assured of the resources in staff as well as equipment and finance needed to enable it to keep pace with the steadily increasing demands resulting from the exponential trends in scientific and technical literature to-day. The parsimony and short-sightedness of successive Governments in the past do not warrant excessive optimism as to the absence of any check to the development of the new Library in the future, and the Ministry for Science and the Advisory Council on Scientific Policy may well need active and sustained interest and support both from industry and from scientists and technologists if progress is to be maintained.

Beyond this, there must be an end to the dilatoriness that hindered the development of the scheme for the new National Reference Library for Science and Invention and has inhibited any action on the Roberts Report towards the evolution of a real national library system. There is still a long way to go, and it is only as part of a national system in which the public libraries, the university libraries and the libraries of the colleges of technology, the professional institutions, a host of special libraries are all linked up with these two new national libraries and the National Central Library that the vision and courage and technique that have gone to the establishment of the new Library opened on November 5 can have their full effect. Those who were present had indeed a glimpse of the possibilities. It now lies with them to ensure that their colleagues in industry, in the universities, the colleges of technology, the Library Association and other professional bodies are made fully aware of those opportunities and of their responsibilities to see, so far as possible, that no lack of vision or false economy limits the project.

Dr. Urquhart has been fully justified in the emphasis he has laid on the economic aspects of library services and functions and in his determination to eliminate unnecessary routine and recording. Only so can the resources available hope to keep commensurate with the expansion visualized over the next century, even when the utmost advantage is taken of mechanization. Impressive, however, as is the mechanization of the new Library, probably the most encouraging feature for the future is the keenness and enthusiasm of its staff. It remains as true to-day as when it was written in these columns more than thirty years ago that the efficiency of the technical library for research purposes is determined as much by the personality and enthusiasm of the librarian as by the mechanical perfection of its indexing system. Growing mechanism, in fact, makes even larger demands on the library staff if the real needs of users are to be met. Their understanding of the problems encountered, their enthusiasm and initiative can go far to offset inherent drawbacks in mechanization. Moreover, if they can scarcely hope, for example, to provide a real substitute for the invaluable browsing which is impossible in a library planned on such lines as the new National Lending Library, such qualities could do much to provide stimulus in other ways, whether in personal contact or initiating new means for exchanging ideas and information. Contrariwise, mechanization of outlook and touch on the part of the library staff could wreck the co-operation and understanding on the part of users of all kinds which, as Lord Hailsham reiterated, is a vital element if this new venture is to realize its full potentialities.

THE SCIENCE OF METEOROLOGY

The Challenge of the Atmosphere

The Science of Meteorology. By Sir O. G. Sutton. (Hutchinson Science Library.) Pp. xiii + 227. (London: Hutchinson and Co. (Publishers), Ltd., 1962.) 21*s*.

THERE is always a risk that the writings of the head of the department in which the majority of meteorologists in the country are employed shall be regarded as being *ex cathedra*. One hopes that his sober statements on the negligible effects of hydrogen bombs on the weather and the slender possibilities for rain-making will be widely studied; but it would miss the point of the book to accept them on account of his authority. Every opinion must be carefully argued, and this is the essence of the "Challenge of the Atmosphere". The basic physics and dynamics of the air have been understood for a long time, but the situations are so complicated that the end-product—the weather—is infinitely varied. By comparison the game of chess, the rules of which are also well known, is trivial.

Meteorology is the most difficult of the physical sciences because the ground is already chosen: it cannot be fabricated in the laboratory to suit the state of our knowledge. Sir Graham takes us through close but delightful argument from a complex physical situation to a statement of the challenge it poses to the intellect, and then extracts the essence and states it in terms of the concepts of classical mechanics and physics. He shows us how one has to think about complicated problems.

If he had dealt only with aspects of the atmosphere in which this kind of approach has been particularly successful, the book would have been biased, and rather dull for the less-philosophical reader. But when he begins to write descriptively, and at second hand, much of the sparkle vanishes, and one can find many better accounts by less-eminent authors. This, however, is a personal point of view, and a newcomer to meteorology might well find the descriptive chapters most interesting at first reading.

The challenge and the philosophy retain their interest even when the theories in terms of which they are stated have been superseded. Thus it is difficult at the distance of three or four decades to believe that anyone really hoped that the atmosphere would turn out to have a constant eddy transfer coefficient. Yet apparently many did. It is obvious nowadays that the magnitude of eddy transfer must depend on the thermal stratification of the air. But how many people who use Sutton's formula for the dispersion of smoke appreciate the niceties of the philosophy by which it was realized that it must also depend on distance from the source ? The chapter on this topic is the most exciting because it is really part of the author's memoirs. However, he does not give us the latest instalment of the story—the realization that mixing length theory is only an aspect of dimensional analysis.

In looking ahead one can readily share his optimism and commend his enthusiasm for the future development of the subject without accepting all the details of his philosophy. In particular, one may question the view that the motion of the atmosphere can be divided into a mean motion with a superstructure turbulence, for he does not adequately face the problem of defining the mean. Because of the non-isotrophy and wave properties of the atmosphere one can also dispute his hope that the ideas of Kolmogoroff will be applicable to it. One could quibble over "All predictions of forthcoming weather are statements of the probability of an event"; while it may be all right for insurance companies dealing with many cases, 'probability' has doubtful meaning in the context of a single occasion and continuously variable possibilities rather than discrete alternatives.

One cannot be quite so happy about his treatment of thunderstorms. The ideas behind C. T. R. Wilson's theory of charge separation are good fun, but they have never been enthusiastically accepted. Also the descriptive account of the life of a thundercloud given by the 1946 *Thunderstorm Project* is interesting though unsatisfactory because it has no sound mechanical basis: and so it is a pity that Sir Graham ignores the insight which has been gained in the past eight years into both the mechanics of showers and the role of the freezing of supercoded droplets in producing temperature differences which cause the charging of ice crystals.

To other minds the atmosphere poses other challenges not discussed in this book, but a personal point of view is always the most stimulating. It is to be hoped that the challenge will be accepted by more of our brighter young scientists in the future.

Finally, the British reader should be warned that the book was obviously written for the American market.

LANGUAGE AND MAKERS OF CHEMISTRY

Historical Studies in the Language of Chemistry

By Maurice P. Crosland. Pp. xvii + 406. (London: Heinemann Educational Books, Ltd., 1962.) 50*s*.

Great Chemists

Edited by Eduard Farber. Pp. xxvi + 1642. (New York and London: Interscience Publishers, Inc., 1961.) 222*s*.

THERE are divers ways of tracing the progress of chemistry through the ages, among which a study of the changing modes of expressing observations and ideas, as adopted in Crosland's book, is not the least interesting. From the dawn of alchemy to modern chemistry the written word has always been intimately associated with symbolic representation. Both these forms of expression as used by the alchemists were marked by a picturesque obscurity: this was largely involuntary, seeing that, in the words of Liebig, the alchemists "propounded in an unintelligible language that which, in their own minds, was only the faint dawn of an idea". Sometimes, however, the obscurantism is found to be deliberate on the part of esoteric adepts "whose noble practise doth hem teach to vaile their secrets with mistie speach".

During the alchemical millenium and the later era of iatrochemistry much knowledge was accumulated concerning chemical operations and materials, so that more precise forms of literary expression and an extended symbolism gradually came into vogue. The ancient planetary symbols for the metals were now supplemented by symbols for individual substances, processes, forms of apparatus, duration of operations, and so forth. But a static terminology could not keep up with a dynamic science; for example, with a growing knowledge of the nature of specific substances, such names as *sal polychrestum Glaseri*, *salt of Mars* and *Mercury precipitate* became outmoded. Later, the clumsy nomenclature of the era of phlogiston gave way to the French system drawn up at Paris in 1787, of which Black complained that by using the "latinized French words" of the French chemists it would in future "scarcely be possible to think on chemical subjects in a way different from their theories". In another field of linguistics a similar plaint may be found in an old folksong of the West Frisians: "We will not let our language go, for without the Frisian tongue there can be no Frisians more".

From the time of Dalton and Berzelius, modern chemical expression, nomenclature and symbolism have become increasingly precise and meaningful; so that an amazing amount of information, both qualitative and quantitative, may be conveyed by a chemical equation or a structural formula.

Crosland has rendered a considerable service to chemistry and chemists by producing an integrated account of a scattered and complex subject: it is well expressed, easy to read, and excellently documented and indexed. The five plates include an interesting reproduction of a photograph of the members of the historic Geneva Congress held in 1892 to consider the nomenclature of organic compounds. There are also eight text-figures of symbols.

In 1871 Clerk-Maxwell wrote: "In Science, it is when we take some interest in the great discoverers and their lives that it becomes endurable, and only when we begin to trace the development of ideas that it becomes fascinating". The massive book edited by Dr. Farber enables the reader to follow both these lines of approach in chemistry. A work of this kind cannot take the place of a history of chemistry; but it can become a valuable aid and incentive to all chemists who are possessed, as they ought to be, of a vivid interest in the origins and progress of their science.

The present list of more than a hundred biographical studies is arranged in chronological sequence, with the interspersion at suitable points of four short 'interludes', acting as a kind of connective tissue. These, as also some of the biographies, are written by the editor under the following titles: "Philosophers and Practitioners, from about 800 B.C. to A.D. 800"; "Philosophical Alchemists and Practical Metallurgists, Thirteenth to Sixteenth Centuries"; "The Chemists' Language"; and "Scientists and Industrialists".

Nearly all the 114 numbered sections of the book are devoted to individual chemists, but there are a few collective sections dealing, for example, with Babylonian and Arabic chemists. Chronological pride of place is given to a certain *Tapputi-Belatekallim*, 'perfumeress' of a Babylonian household, whose name, to adopt an alchemical phrase, has been "brought out of the black darkness" of centuries through the medium of a cuneiform tablet of ancient Mesopotamia. The individual biographies vary a great deal in treatment, a feature which breaks the possible monotony of a work of this kind. Thus, Lord Brougham's charming personal reminiscences of Joseph Black could not carry an evaluation of his researches and views such as we find in Prof. Partington's detailed and very fully documented account and assessment of van Helmont. Many of the biographers are themselves eminent chemists, and the articles are often reprints or translations of earlier notices. The sequence extends to modern times, but no living chemist is included.

Portraits of the subjects form a welcome addition, but a few of them have suffered in reproduction: also it would have been of interest to know the ultimate provenance of each. Naturally, a selection of a limited number of great chemists must always be somewhat arbitrary; but it is certainly surprising to miss the junior W. H. Perkin from this list. Indeed, Ruzicka refers to him in this very volume as "the complement of Wallach in the history of the chemistry of the terpenes, as well as of organic chemistry in general . . . the great synthesist, William Henry Perkin, founder and unrivalled master of alicyclic synthesis"—and, of course, of much else in organic chemistry.

This age-long cavalcade of chemistry, charged with human interest, variety and colour, fully deserves the motto of Nicolas Flamel, the Parisian alchemist of the early fifteenth century: *Moult plaist a Dieu procession, S'elle est faicte en devotion.*

John Read

SOCIETY: A PIECEMEAL VIEW

Society

Problems and Methods of Study. Edited by A. T. Welford, Michael Argyle, D. V. Glass and J. N. Morris. Pp. vi+586. (London: Routledge and Kegan Paul, Ltd., 1962.) 50*s*. net.

THIS work is introductory, "intended both for those setting out upon a systematic study of social processes, and also for those whose main interests lie elsewhere but who wish to orientate themselves in particular parts of the field". It consists of thirty-one different contributions, each by a different author or authors, and is divided into two parts, the first emphasizing various approaches and methods and the second examining a number of areas of study.

Inevitably, the particular contributions vary in quality, and in the extent to which they meet the objectives of the book. Some, such as those on the census, on the measurement of abilities, attitudes and personality traits, and on experimental studies of small social groups, place too much emphasis on technical details at the expense of the general significance and limitations of the work discussed. Others are too introductory and descriptive—for example, the contributions on personnel selection and vocational guidance, on urban sociology and on rural sociology. Not many of the articles are really outstanding, although honourable mention should be made of those on social medicine, on social factors in the major functional psychoses, on social mobility and on the sociology of education.

As the editors allow, selection is always a problem in a work of this kind. Nevertheless, some of the decisions made are curious. Contributions are included on road accidents, on operational research and on operational research in industry which have virtually no 'social' content at all, although the questions discussed might well have been approached with this emphasis. On the other hand, a number of important questions in the field of social administration, which are very relevant to social policy, such as poverty, are ignored. These omissions cannot be excused on the grounds either that it was desired to limit contributions as far as possible to those from sociology, or that applied research was to be excluded. The particular examples already quoted suffice to emphasize that the book covers studies of many miscellaneous aspects of social processes, contributed by a variety of disciplines, and ranging from the basic to the most applied approach.

The serious weakness of the book lies, however, in the absence of any overall view. The four editors assure us in the briefest of introductions that "the editorial hand has been kept light"; it certainly has, and in respect of the absence of a satisfactory introduction the editors appear to have underestimated their responsibilities. Particularly in an introductory text, it is essential that the reader be given a clear and concise outline of the wood before he is plunged among the trees. Moreover, as several of the individual authors stress, the boundaries between the different areas they discuss are often no more than convenient conventions, and theoretical considerations seem to suggest increasingly that less attention should be paid to them. An introduction on the main social sciences, emphasizing the distinctive approach and hence limitations of each, would have added greatly to the value of an introductory work of this kind, which is wide-ranging yet very specific in each of its many parts. This would have served not only to highlight the complementariness of the approaches of various social sciences for the study of certain problems; it would also, by providing an overview, have made it easier to appreciate both the relevance of the particular techniques discussed and the adequacy of the research into specific problems which is described.

W. H. Scott

ANCIENT GLASSES

Analyses of Ancient Glasses, 1790–1957

A Comprehensive and Critical Survey. By Prof. Earle R. Caley. (Corning Museum of Glass Monographs, Vol. 1.) Pp. 118. (Corning, New York: Corning Glass Center, 1962.) n.p.

ALTHOUGH the town of Corning, the headquarters of the famous glass-making concern of that name, is in up-state New York, many miles from large centres of population, the Glass Center there was visited by hundreds of thousands of people in the first few months after opening. In the Glass Center the Museum of Glass and the Stuben glass house, where the extremely high-quality decorative pieces are made, are open to the public; in addition there is a fine library of books on glass and facilities are provided for scholars studying the history of the art and technology. As another means of fostering such studies the museum is to publish monographs, from time to time, of which the present volume is the first.

This is a very handsome quarto volume in which the results of analyses of ancient glass are collected, beginning with the work of Klaproth (1743–1817) and covering publication up to 1957. Prof. E. R. Caley, who has for many years been applying his chemistry to archæological subjects, was obviously well chosen for the present task. The first chapter describes in detail Klaproth's analyses, published in 1801, of some coloured Roman glasses, and they were surprisingly good; the remainder of the chapter discusses analyses, mainly of Roman and Egyptian glasses, carried out by various people up to about 1880. The critical commentary directs attention to analyses that would preferably be repeated using modern methods and facilities and, unfortunately, often notes with regret the lack of careful description of the place in which the specimen was found and its probable date.

The long second chapter reports investigations of the past fifty years, many of which are concerned with ancient coloured glasses. Copper and manganese and the ever-present iron are the main sources of colour; some Egyptian yellow and brown glasses are shown as containing up to 1 per cent of sulphur, but Prof. Caley does not appear to suggest that these might be what are now described as 'iron–sulphur' ambers. Several deep blue glasses are mentioned in this section, but cobalt is shown to occur only in a few of these until the work of Farnsworth is reached; he apparently settled a controversy about the presence of cobalt in blue Egyptian glasses and showed that many, but not all, of the deep blue glasses did contain cobalt.

Chapter 3 deals specifically with Egyptian glasses and includes a discussion on the sources of raw material.

The next two chapters consider glass from the Near and Far East and Roman glass, and there is a final chapter on altered or decomposed ancient glass. Altogether it is a most interesting and scholarly book which has set a high standard for the series of monographs of which it is the first. R. W. Douglas

RARE EARTH METALS AND THEIR ALLOYS

Rare Earth Alloys

A Critical Review of the Alloy Systems of the Rare Earth, Scandium and Yttrium Metals. By Dr. Karl A. Gschneidner, Jr. (Prepared under the auspices of the Office of Technical Information, United States Atomic Energy Commission.) Pp. xiii+449. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1961.) 96s.

This compilation of physical properties of the rare earth metals and their alloys is primarily for those engaged in metallurgical research, although workers in the field of applied research and solid-state physics should also find portions of the book useful. Although yttrium and scandium are not members of the lanthanide series, because of their similarity and association with the rare earths, they are included as part of the same group.

The book is divided into four main sections. In the first section the author deals with the physical properties of the pure rare-earth metals. In the chapter devoted to the electronic structure of the metals, Dr. Gschneidner gives the outer configuration as $(5d)^1$ $(6S)^2$ except for europium $(4f)^7$ $(5d)^0$ $(6S)^2$ and ytterbium $(4f)^{14}$ $(5d)^0$ $(6S)^2$. While the majority are predominantly trivalent in their chemistry and Yb and Eu are divalent in the metal, the recognized configuration, at present, of the outer shells is $(5d)^0$ $(6S)^2$ except for gadolinium $(4f)^7$ $(5d)^1$ $(6S)^2$ and Lu $(4f)^{14}$ $(6d)^1$ $(6S)^2$. This should be borne in mind when the author is discussing the validity of the hypothesis put forward by the Russians on the work function of some of the rare earth hexaborides.

Section 2 is concerned with the alloy systems involving rare earth metals as one or more of the components. Each system is followed by information on its crystallographic, physical, thermodynamic and mechanical data. In the introduction to the general alloying theory the author makes use of a modified form of the Darken and Gurry plots for selecting elements likely to form extensive solid solutions. This type of prediction should only be used with care since several examples are known of non-rare earth systems, for example, copper–gold, silver–copper, where extensive solid solutions are formed with the solvent which would be predicted otherwise when based on the given Darken–Gurry plots.

In the presentation of the phase diagrams the author has taken into account the data given by the experimenters reviewed, such as purity and melting points of the elements used, techniques, etc. The resultant diagrams are constructed from the most reliable data, in the author's opinion, and many are composites made up of two or more sources.

Section 3 includes crystallographic details of atomic positions and parameters, and has been arranged according to the Strukturberich notation. In Section 4 there is a list of more than 650 references and an excellent cross-referenced index of the alloy systems.

Dr. Gschneidner has reviewed the data of some sixty-years work and has presented it in a concise and well-written volume. One of the most valuable aspects of this book lies in the comprehensive bibliography of work published up to 1960, and it is as a reference book for those engaged in, or who are about to be initiated into, the metallurgy of the rare earth metals and their alloys that this book will be most appreciated. J. G. Day

POLAROGRAPHY

Progress in Polarography

Edited by P. Zuman, with the collaboration of I. M. Kolthoff. Vol. 1: Pp. xiv+1–356. Vol. 2: Pp. x+357–807. (New York and London: Interscience Publishers, 1962.) 85s. each volume.

These two volumes present a comprehensive international coverage of recent trends and advances in both polarographic research and instrumental development. The individual sections are written by research investigators of acknowledged status in the electrometric field, and although the present publication, for this reason, will possess a considerable appeal to the expert, there is much detail lucidly presented which will prove of greatest value to the tyro polarographer.

Marie Heyrovska, in the first chapter, gives an interesting historical record of the growth of polarographic science, and lists those text-books, journals, reviews and research papers which have been published in the period 1931–60.

In recent years, as a producer of polarographic research papers, Czechoslovakia easily heads the list of those twenty-three countries which have made published contributions in this field. When one considers that this science originated with Prof. Heyrovsky at Charles University, and that Prague has a Scientific Institute uniquely devoted to polarographic studies, the result of this census of related papers is not surprising.

Volume 1 has a distinctly theoretical bias which is largely balanced by the more practical tone of Volume 2. It is impossible in a review of this nature to mention all the eminent contributors by name; but in order to illustrate the general nature of the work it may be noted that Volume 1 has theoretical papers on polarization and electrode kinetics (Randles); double-layer structure (Delahay); kinetic currents (Brdicka *et al.*); adsorption (Reilly), etc. More practical approaches are made by Reynolds (inorganic polarography) and Zuman (organic substances). Fujinaga describes the infrequently practised technique of constant current polarography.

Volume 2 has chapters on modern instrumentation in the United States, Japan and Europe written by Meites, Tanaka and Serak respectively. Square wave and pulse polarography are concisely described by Barker. Zagorski describes recent refinements in polarographic cells; Kolthoff and Okinaka present a valuable paper on newer electrode systems; and Kemula outlines his now well-known chromato-polarographic technique. Milner's succinct description of sample treatment should prove of greatest value to practising analysts.

The second volume concludes with several readable chapters by various specialist authors on the applications of polarography to metallurgical, pharmaceutical, biochemical and other related forms of analysis.

There can be little doubt that as a collection of up-to-date reviews of scientific advances in this ubiquitous field, this publication will win much acclaim from those serious disciples of the Heyrovsky method. D. T. LEWIS

AN INTRODUCTION TO MAMMALS

Introduction to Mammalogy

By Prof. E. Lendell Cockrum. Pp. viii+455. (New York: The Ronald Press Company, 1962.) 9 dollars.

Laboratory and Field Manual for Introduction to Mammalogy

By Prof. E. Lendell Cockrum. Second edition. Pp. v+116. (New York: The Ronald Press Company, 1962.) 4 dollars.

THE production of a book designed primarily for college students and entitled *Introduction to Mammalogy* would seem to be an ideal opportunity to correct the impression frequently given by an orthodox, elementary, vertebrate course that the class Mammalia consists of rabbits and rats (with dogs' skulls). The book is divided into two sections, the first comprising six chapters on the "Biology of Mammals", and the second a systematic treatment of the class with an account of each family. Both parts leave much to be desired. The first section is indeed a useful and comprehensive account of general mammalogy, but it seems a pity that the opportunity was not taken to omit much that can be found in any vertebrate text-book, and include more information on more strictly mammalian characteristics. Much space is occupied by trivialities, for example, the same space (one paragraph) is taken to describe the fluorescence of some pelages under ultra-violet light as to describe the scent-glands, which play a dominant part in the life of most species of mammals. Inaccuracies abound; for example, in the labelled illustration of a skull (coyote) the zygomatic arch is called the rostrum and the mandible the maxilla.

The systematic section would be an invaluable compilation if it were accurate. In fact errors occur on page after page. Each family is accompanied by a map of its world distribution, most of which show gross inaccuracies. For example, the Dasypodidae (armadillos) are shown to be confined to the north-eastern half of South America, when in fact they reach Patagonia; apes are shown on the East African coast; the Indian river dolphin is correctly described in the text as being confined to the Rivers Ganges, Brahmaputra and Indus, but although these rivers are clearly indicated on the map they are left blank, while southern peninsular India is shaded: rhinoceroses are indicated as absent from both India and West Africa, which fortunately is not yet the case; and squirrels are shown to be absent from West Africa, a situation that would save many a taxonomic headache if it were true! The text is scarcely more reliable. The statement that the gaur (the Indian wild ox) is a typical African species is enough to dispel any confidence in any of the great mass of potentially valuable information contained in this volume.

The accompanying laboratory and field manual contains keys to the genera of North American mammals and many useful suggestions for practical work. But the exercise of filling in blanks with observations is scarcely likely to develop an original, inquiring approach to any subject.

G. B. CORBET

PATHOLOGY OF TREES AND SHRUBS IN BRITAIN

Pathology of Trees and Shrubs

With special reference to Britain. By T. R. Peace. Pp. xx+723+16 plates. (Oxford: Clarendon Press, 1962.) 90*s*.

THIS is no mere description of diseases of trees and shrubs. It is far more than that, and it is so compiled and written that it will be of great value to those interested in the pathology of trees and shrubs, be they forester, student or research worker.

More than one-third of the book is devoted to an exposition of the various agencies which may cause damage to trees such as climate, unsuitable edaphic conditions, man, animals, insects and plants. This section includes well-written summaries of diseases of general importance in the nursery and on stems, shoots and leaves. Then follow chapters on the diseases of forest trees grown in Britain and a chapter on the diseases of ornamental trees and shrubs. Control, pruning, tree surgery and quarantine measures are adequately dealt with and there is a valuable list of host species. All this information is due to the author's own experience in Britain, in Europe and in North America, and to his having consulted a vast amount of world literature. The listed bibliography amounts to nearly 2,500 entries and this section alone will be of great worth to research workers and others requiring more detailed information about a particular subject.

Although one agrees to a certain extent with the author's contention about changes in botanical nomenclature, it is a pity that he has held out so strongly against such names as *Picea abies* and *Quercus petraea*, which even most diehards have accepted, except perhaps some French foresters.

The author is quite emphatic about not attempting to provide keys for identification purposes. The book is concerned with the symptoms and diagnosis of tree diseases and therefore details of spore-sizes and microscopic anatomy of fruit-bodies have no useful place in it and would add considerably to the book's already large size if they had been included.

In the preface Peace feels that he may have been over-ambitious in attempting to cater for a wide range of needs. No apology is required, for a work of this kind has long been wanted. It has succeeded by the material provided and by the way it has been presented and illustrated. Tom Peace was chief research officer of the Forestry Commission. This book is a worthy memorial to his work. His untimely death last September more or less coincided with the date of publication. C. J. TAYLOR

THE ROYAL SOCIETY

ANNIVERSARY ADDRESS*

By Sir HOWARD FLOREY, F.R.S.

AWARD OF MEDALS, 1962

Copley Medal : Sir Cyril Hinshelwood, O.M., F.R.S.

THE contributions of Sir Cyril Hinshelwood to chemical research have been recognized repeatedly, and universally. Most of his scientific work has been concerned with the mechanism of a wide variety of chemical reactions, homogeneous and heterogeneous, and in all states of aggregation. These have included processes of fundamental importance in both chemistry and biology. His work has been characterized by a flair for the elucidation of complex processes by the ingenious planning of relatively simple experiments, together with a remarkable insight into the implication of the results. He has influenced the whole pattern of research in chemical kinetics during the past forty years.

His early investigations of the mechanism of homogeneous gas reactions clarified theories about molecular activation through collisions, and also led to new ideas about chain propagation in thermal systems. He developed the theory of branched chain explosions, and by a skilful use of both catalyst and inhibitors he has disentangled many complex reactions involving free radicals. In the course of this work he has made important advances in our understanding of combustion and also of some reactions of hydrocarbons which are of considerable practical significance. From measurements on reactions in the liquid phase he has been able to discover essential differences from the corresponding gaseous processes.

He has applied the principles of chemical kinetics to study the growth of bacteria, and in particular their adaptation when subject to special influences during growth. He has analysed the stages of the growth process and the effect on them of different growth media, of inhibitors, and of specific elements. In this way he has been able to discover much about the mechanism of drug resistance and to provide a new approach to many problems of bacteriology.

Hinshelwood's ability as a brilliant expositor is well known. He is truly a natural philosopher in the classical tradition, versatile in the arts and the sciences, and no one has been more faithful to the aims of the Royal Society for the Improvement of Natural Knowledge.

Rumford Medal : Prof. D. M. Newitt, F.R.S.

D. M. Newitt has been an outstanding investigator for many years in the field of chemical engineering, and is particularly well known for his work at high pressures. Starting in 1923 from work on combustion in gaseous systems at high pressure, he moved on through studies of slow oxidations to reactions in the liquid phase at pressures ranging up to 20,000 atmospheres. He made fundamental observations in physics, thermodynamics and chemistry, and the work involved the solution of major engineering problems in the design of appropriate plant-pressure vessels, compressors and measuring apparatus. The field is complex in its basic science, highly important in its technological application and hazardous in its exploration. Newitt is an acknowledged master in it.

He has also made important contributions to our knowledge of gaseous combustion, ignition, explosion and pyrolysis. In the field of chemical engineering his researches have included important studies of the drying of solids, and of the theory and practice of mining, agitation and granulation.

He has for forty years been associated with the development of chemical engineering as a distinct discipline both professionally and educationally, and he has a distinguished record of public service, both in the two World Wars and in peace.

A Royal Medal : Prof. S. Chandrasekhar, F.R.S.

Prof. Subrahmanyan Chandrasekhar has for many years conducted intensive and highly successful mathematical investigations into the difficult subject of the stability of motion of real (viscous) fluids. It is well known that many of the peculiar difficulties of hydrodynamics arise from the fact that although relatively simple patterns of flow, amenable to mathematical analysis, can occur with certain geometrical shapes of the boundaries, all such motions are inherently unstable in that the patterns are liable to break down if their characteristic parameters exceed certain limits. It is the task of the mathematician to elucidate the mechanism of transition from one state to the other and thus help to bridge the gap between the dynamics of ideal and real fluids.

Such a task calls for the most painstaking and intricate mathematical analysis coupled with strong physical insight. These are the qualities that Chandrasekhar has brought to bear. The problem attracted the attention of mathematicians and physicists since it was first noticed by James Thomson in 1882; but it is to Chandrasekhar that we owe the most thorough-going and complete analysis.

Convection is of fundamental importance to meteorology, geophysics and certain aspects of astrophysics, and Chandrasekhar has extended the original investigation, notably by discussing quantitatively the effects of rotation and of an externally impressed magnetic field. He has also made significant contributions to the problem of the onset of thermal instability in fluid spheres and spherical shells with internal heat sources, essential topics in the examination of patterns of convective motions which might occur in the fluid core of the Earth and in relation to theories of the origin and nature of the Earth's magnetic field. Among other problems that he has studied in the same general field, the stability of Couette motion, of flow between coaxial cylinders and of stratified fluids, must be mentioned. All these have profound implications for the environmental sciences.

Chandrasekhar's superbly efficient mathematical technique has enabled him to replace much of the empiricism which formerly characterized this study by mathematical rigour, and has thus provided the environmental physicist with the tools necessary for the development of the subject on sound lines.

---

* Delivered at the Royal Society on November 30.

A Royal Medal : Sir John Eccles, F.R.S.

Anyone who attempts to review the research of Sir John Eccles is faced with a formidable task. Since his early work with Sherrington in the late 1920's, Eccles has produced a steady stream of scientific papers and books. The main theme of his work has been the investigation of the mammalian spinal cord. At first the inquiry was along Sherringtonian lines, and reflexes were described in terms of central excitatory or inhibitory states. Then followed a period in which Eccles tried to frame an electrical theory of central nervous action. Later, he became convinced of the essential correctness of the chemical theory of synaptic transmission, and during the past ten years he has been one of the most enthusiastic exponents of the role of chemical transmitters at synapses. Perhaps his most important contribution is the demonstration that there are clear-cut electrical differences between the central effects of excitatory and inhibitory impulses. Using microelectrodes to measure the membrane potential of motoneurones, Eccles and his colleagues showed that excitatory impulses caused a transient breakdown of the electrical potential difference across the surface, while inhibitory impulses stabilized the potential difference at or near the resting level. More recently, he has directed his attention to the demonstration and analysis of a phenomenon newly observed in the central nervous system, that of presynaptic inhibition.

Besides his massive studies of the central nervous system, Eccles has made important contributions to our knowledge of smooth muscle, of neuro-muscular transmission and of the differences between various kinds of skeletal muscle. Red muscles such as the soleus give longer twitches than white muscles such as the gastrocnemius. The difference resides in the muscles and cannot be attributed to the type of message which travels down the nerves, yet Eccles and his colleagues have shown that if the nerves which normally supply fast and slow muscles are crossed, the fast muscle becomes slow and the slow one becomes fast. The reason for the change in behaviour is unknown, but the phenomenon is clearly of great interest, both for its own sake and for the light which it may throw on the differentiation of tissues during development.

Sir John Eccles has established a flourishing school of neurophysiology at the Australian National University, Canberra.

Davy Medal : Prof. H. J. Emeléus, C.B.E., F.R.S.

Prof. Emeléus has been recognized for many years as an outstanding inorganic chemist, and it is almost entirely due to his researches and his influence that there has been a revival in Great Britain of interest in this field, leading to the discovery of new compounds of unexpected value and importance.

His first interests were the oxidation reactions of phosphorus, sulphur and arsenic, and similar chemiluminescent processes, and he sought to clarify these processes by isolating intermediate species such as sulphur monoxide. His attempt to extend the ideas of reaction chains to the supposedly spontaneous oxidation of volatile hydrides led him into the chemistry of silicon hydrides and chlorosilanes, of germanes and related compounds, fields of inorganic chemistry where little was known. He continued work on the pyrolysis of silanes and germanes, but the emphasis shifted from the physicochemical aspects to the inorganic chemistry of compounds which were, or could be, formed. He studied the chemistry of the higher silanes, synthesized and examined derivatives of the silyl radical, and devised new reactions by which a variety of halogenated silanes are formed.

Some twenty-five years ago he took up the long-neglected subject of fluorine chemistry, and became involved in the separation of uranium isotopes by thermal diffusion using uranium hexafluoride. This work led him to new developments with fluorides of non-metallic elements such as sulphur, arsenic or antimony, and with interhalogen compounds. He studied the reactions of bromine trifluoride and iodine pentafluoride, discovered and interpreted the electrical conductivity and reactions of solutions in these media, and also the formation of new kinds of interhalogen anionic complexes based on the auto-ionization of bromine trifluoride and iodine pentafluoride. He took up intensively the organometallic chemistry of perfluoroalkyl compounds, and this is still yielding a wealth of valuable knowledge.

In the course of all this work, Emeléus has developed new experimental techniques for handling the volatile and reactive metallic fluorides and for studying their reactions. Throughout, he has displayed skill and refinement in the methods he has chosen for isolating and characterizing materials, placing emphasis on experimental and analytical techniques and where relevant on the use of physical methods.

Darwin Medal: Prof. G. G. Simpson, For.Mem.R.S.

Prof. G. G. Simpson, former curator of fossil mammals and birds in the American Museum of Natural History, may be regarded as the leading authority on mammalian palæontology and as one of the most important writers of to-day on the general theory of evolution.

He first established his reputation by two outstanding monographs on Mesozoic Mammalia of America and in the British Museum (Natural History). Since then he has produced a continuous succession of important papers dealing with fossil mammals—in particular those from Palæocene and Eocene levels. Also noteworthy are his studies of cretaceous Mongolian insectivores, of the Oligocene tupaiid *Anagale*, and of Palæocene and Eocene primates.

His fine book on *The Principles of Classification and a Classification of Mammals* was published in 1935. This extensive study is now regarded as the standard work of reference on the classification of mammals. His book on *Tempo and Mode in Evolution*, published in 1945, is perhaps the most serious attempt yet made to apply the data of palæontology to the quantitative study of rates and determinants of evolution, and the elucidation of evolutionary factors such as the role, intensity and direction of selection, the nature of adaptation, and the mechanism of speciation. His most recent book, *The Principles of Animal Taxonomy*, is likely to be for many years the standard work on one of the most important branches of biological thought.

Buchanan Medal : Sir Landsborough Thomson, C.B., O.B.E.

Over a period of nearly forty years, Sir Landsborough Thomson has given outstanding service as an administrator of research in the medical and biological fields. He joined the headquarters staff of the Medical Research Council in 1919 when it was still a small organization, and remained with it as deputy to the Secretary until his retirement in 1957. During that period the Council's activities and responsibilities expanded until they were of national scope, and it was Thomson who was primarily responsible for its administrative policy and method of working. By his consistent good sense and informed understanding he maintained within the Council's organization that administrative flexibility which is essential to any organization which aims at forwarding the progress of research.

Thomson's approach to each problem as it arose showed his high quality and the breadth of his wisdom, so that his advice was widely sought not only by his administrative colleagues but also by research workers both within and without the Council's employ and on problems which concerned other organizations besides his own. His combination of administrative skill and scientific understanding made his administration a model which had influence beyond his immediate field.

In this achievement Thomson was substantially helped by his own scientific interests in biology, interests which led him ultimately to election as president of the Zoological Society of London.

Hughes Medal : Prof. B. Bleaney, F.R.S.

Prof. Bleaney is distinguished for his experimental work on magnetic and electrical phenomena and the interpretation of the results in terms of atomic and molecular properties.

During the Second World War he was engaged on the design of the first klystron oscillators for the production of 3-cm and 1-cm waves, and constructed prototypes for the models which were later produced commercially. He used these new sources of long wave-length radiation to make the first analysis of the spectrum of ammonia by what is now generally called microwave technique. He also made measurements on the broadening of these inversion lines both by ammonia itself and by added gases, and obtained estimates of the collision diameters.

Most of his other work has been connected with paramagnetic resonance. He first made measurements at low temperatures and showed that transitions occur in the chrome alums. Later, he discovered and analysed hyperfine structure with manganese and cobalt salts. He has determined the nuclear spin moments, magnetic moments and electrical quadrupole moments of a large number of nuclei, including some radioactive species. His paramagnetic measurements have also been applied in studying the structure of a number of inorganic crystals. His early work was the basis of theories on the paramagnetism of the rare earths and of neptunyl and plutonyl compounds.

He suggested the first successful method of nuclear alignment, which has since been widely applied.

ACTIVITIES OF THE ROYAL SOCIETY

This year is the tercentenary of the granting of our first Charter by Charles II, and the occasion was celebrated by a soirée at which we were honoured by the presence of one of our Royal Fellows, Her Majesty Queen Elizabeth, The Queen Mother. This important milestone in our history has been marked by some evidence that the activities of the Society are still growing, for our capacity to foster research has recently been substantially increased. The Government has promised us funds to establish five research professorships, to which are attached resources to finance at least part of the work associated with them. Our gratitude to the Government is great for what is, in effect, a very large new endowment. This recognition of the part we can play in helping investigation is greatly to be welcomed, both for itself and because it directs attention to a way in which we can keep vigorous the Founding Fathers' idea that the Society exists for "improving natural knowledge". In the rapidly changing times in which we live some of the functions that the Society used to have may disappear, and during the coming years interest in promoting research may have to be exerted in ways undreamed of by the original Fellows. Let us hope that the Government's initiative will prove fruitful in our hands, and that in the future the number of such professorships will be increased still further.

We are also indebted to the Leverhulme Trust for asking us to administer a new scheme for appointing visiting professors to India. Such a scheme is perhaps an example of how we may all profit from the changing conception of Commonwealth ties.

The fact that we have been supported by both the Government and the Leverhulme Trust in this way is a clear indication that confidence still persists in our capacity to assist scientific research. But the present complexities of the financing of science by the Government has made unnecessarily difficult certain activities which the Society used to administer with relatively little trouble. I refer to such matters as organizing expeditions promoting investigation of the Sun, fostering foreign relations and so on. We can, therefore, heartily welcome the setting up of a Government body, commonly known as the Trend Committee, to review the methods of financing civil science. We hope that, among other things, some of the Society's difficulties will be lessened as a result of its deliberations. As Fellows know, the Society is doing its best to produce for this Committee the considered views of its fellowship.

I should like to mention two other matters which appear to be of more than usual importance. I said last year that the possibility of improving the accommodation of the Society, which has been deficient for so many years, was being explored, and I had hoped that by this anniversary meeting I should have been able to tell the Society in some detail what has been going on. All I can say at present, however, is that negotiations for improved accommodation have proceeded so far that unless unexpected and insoluble difficulties arise I shall look forward to giving a cheerful presidential address next year on the history of the accommodation of the Society, thus bringing up to date what was said by Sir Henry Dale in 1943.

The other matter which has occupied a good deal of attention of the Council and Fellows is whether we should increase the number of Fellows elected annually. It appears that there is a fairly even division among the Fellowship as to the wisdom of increasing the numbers at this time. As a preliminary to taking a decision in this matter, a Committee of Council has overhauled the methods of nomination and selection and has made suggestions which we hope will be an improvement on previous practice. In due course new draft statutes will be presented to Fellows.

During the often interesting discussions which took place on these matters, I fancied that I detected some signs that the members of most sections thought that they could do with a few more places, but that their colleagues in other disciplines were not quite so well placed: and further, I believe I saw signs that those on the 'A' side were a little worried that those of us on the 'B' side were not quite up to standard. There is little doubt that one of the difficulties of the times is for scientists trained and oriented in one or two disciplines to understand what colleagues in other disciplines are doing, and indeed how they set about solving their problems.

SCIENCE AND HUMAN PATHOLOGY

It occurred to me that as those who attend the anniversary meeting have not been forced to listen to a pathologist before, I might be permitted to spend a little time in letting those Fellows who are not professional pathologists or medically qualified have a glimpse of some of the methods that are used to try to elucidate the causes of disease, and to show that the solution of many pathological problems demands the employment of diverse techniques.

There is perhaps at the present time a tendency to disparage too many scientific observations which have no experimental content, and indeed I was somewhat startled this year to know that a certain body had turned down some proposals carefully thought out by a Committee of the Society on the ground that the intended work was merely the collecting of data. A great deal of pathology, at least in the past, has been data-collecting, and it would be a bold man who would proclaim that this had been unfruitful. Perhaps I can illustrate my point adequately if I select one disease which is now a household word. I refer to coronary thrombosis, a condition which is responsible for much disability and many deaths, and of which we hear a great deal too much in connexion with our friends. Much of our knowledge of the underlying changes in this condition has been acquired by the classical methods of pathology, namely, observation of the diseased parts after death and the correlation of the findings with the symptoms that the patient had while alive.

The disease of the arteries underlying coronary thrombosis is now commonly known as atherosclerosis, and that it is not exclusively a by-product of modern civilization is demonstrated by the fact that fragments of the aorta from Egyptian mummies dating from about 1500 B.C. to A.D. 525 show typical lesions. It is perhaps not inappropriate that one of the earliest descriptions of the disease is that of the aorta of a famous anatomist, J. J. Wepfer, who died in 1695 at the age of seventy-five. The picture of his aorta has a somewhat macabre association for it was published in a posthumous edition of Wepfer's own anatomical observations.

So long ago as 1770, Edward Jenner, famous for his introduction of vaccination, and who, may I remind you, was a Fellow of the Society, first noticed the connexion between certain pains in the chest and narrowing of the arteries supplying the heart. In 1850, Cruveilhier connected disease of the arteries of the heart with alterations in the blood which led to obliteration of the arterial lumen. The activities of the morbid anatomists and morbid histologists, which have been intensified in recent times owing to the apparent great increase in the evil consequences of arterial disease, have now furnished a picture of what may happen in the arterial wall.

The wall of a normal artery, such as one of the coronary vessels which supply the heart, consists of an inner lining of flattened cells, called endothelium, which adhere to a tissue consisting of mucopolysaccharides in which are interwoven fibres of collagen and elastic tissue. This internal layer, known as the intima, lines the main pressure-resisting layer, known as the media, which consists of elastic tissue, collagen fibres, and smooth muscle cells. External to this there is an adventitia which consists of small blood vessels and fibrous tissue. The changes leading to well-developed atherosclerosis occur in the intima just subjacent to the endothelial lining. Precisely what the initial changes are still escapes detection for even the electron microscope has so far not yielded anything of a striking nature.

Features of the fully developed disease are, however, easy to recognize. The obvious lesion of atherosclerosis is thickening of the arterial intima due to the formation of new collagen fibres and elastic tissue, an increase in the number of smooth muscle cells, and the deposition of lipid substances. Not only does this thickening tend to constrict the lumen of the vessel, but also its presence may encourage the formation by the blood of a thrombus at the site, leading to the all too familiar disease of coronary thrombosis. The thickened intima, besides containing deposits of lipid, often in the later stages accumulates considerable amounts of calcium salts, with consequent hardening of the vessel wall in that part.

The prominent lipid material, which is composed of cholesterol and cholesterol esters as well as phospholipids and glycerides, has attracted attention for more than a century, and the theory has been propounded that the disease is produced by abnormalities in the blood lipids, so that these are deposited in the intima in excessive quantities after being released from combination in the lipoproteins of the blood. When not combined in the lipoproteins they are relatively insoluble, so they may remain in the intima for an indefinite time.

To test these views, an enormous body of data has been collected on the level of cholesterol, the phospholipid/cholesterol ratio and lipoprotein concentrations in human blood, in populations living in a wide variety of nutritional and environmental circumstances. These statistical studies tend to show that populations that have a low level of blood cholesterol have relatively little coronary thrombosis. Whether this type of research will provide crucial clues about the cause of the disease remains to be seen, but up to the present no proposition arising from these investigations has received universal acceptance.

Other methods of investigation depend on the work of biochemists and physical chemists, who are investigating in great detail the composition of lipids met with in the body and in arterial lesions. Considerable interest has been aroused in the discussion of whether the kinds of fatty acid which are met with in lesions of atherosclerosis are of importance. One school of thought maintains that the polyunsaturated fatty acids are all-important and that a relative lack of these in the diet is the cause of the disease, while others on what appears to be good evidence deny that this is so. So far a mass of statistical, biochemical and biophysical observations has not produced any satisfactory or agreed solution about the cause of the disease.

It may well be asked whether a crucial experiment could not be performed to demonstrate whether cholesterol really is of importance in the development of arterial disease. Experiments, which at a first glance would seem to have returned an unequivocal answer to this question, were performed by Anitchkov more than forty years ago. He fed very substantial amounts of cholesterol to rabbits, which normally have a low level of cholesterol in the blood and a low intake of cholesterol from the foodstuff. The rabbits developed after some weeks or months lesions of the arterial wall which bore some resemblance to those of the human disease; but these and similar experiments in other species suggest that the lesions produced are not identical with those seen in man. Nor after many investigations is it even clear precisely how the cholesterol is deposited in the arterial wall.

At the present time the possibilities of comparative pathology are being explored by investigating whether the natural arterial diseases which occur in domestic and wild animals have any similarity to those of man. If a species could be found in which the lesions that occur spontaneously are so far as can be ascertained identical with those in man, the way would be open to a more penetrating experimental study. Some observations of great interest have been made during recent years on pigeons. It has been found that in a breed known as White Carneau, gross lesions occur in the aorta of all birds more than three years old, and that these lesions bear a striking histological resemblance to those of man. But of further interest is the fact that while White Carneau and Silver King pigeons develop lesions of this nature, other strains known as Shoe Racer and Racing Homer do not, even when fed on identical diets of grain and kept under the same conditions of housing and exercise. The occurrence of these susceptible and non-susceptible strains has enabled their discoverers to make a comparative study of the various factors which might be concerned in the development of lesions. Their different susceptibilities cannot be attributed to differences in the cholesterol phospholipid or β-lipoprotein levels, for both susceptible and non-susceptible strains have what would be considered in mammals a high blood cholesterol, of the order of 300 or more milligrammes per cent. There is certainly a genetic element here, and at the present time a detailed examination for possible inherited biochemical abnormalities is being conducted on this species.

Recent investigations of the domestic pig have shown that it suffers from a disease which appears to be indistinguishable from the early stages of the disease in man. In my opinion the way is open for the performance in this species of some decisive experiments on the role of diet in the genesis and development of atherosclerosis. The pig resembles man in its omnivorous habits, and surpasses man in its ability to take diets of peculiar composition without complaint. It is indeed an excellent experimental animal for the exploration of dietetic factors. Such experiments might well resolve some of the unsolved problems which have been thrown up by the collection of data in man.

While much attention has been concentrated on the behaviour of lipids, both in the arteries and in the body in general, it must not be forgotten that other components of the tissues are altered in arterial disease. There may well be changes in the mucopolysaccharides of the matrix in which the fibres of the intima are set, but methods for investigating these substances are very imperfect and so far no clear indication has been obtained that the origin of the disease is to be found in aberrations of the mucopolysaccharides.

Changes also occur in the elastic tissue of the vessel wall very early in the development of atherosclerosis. It is not very many years since atherosclerosis was generally considered to be a natural part of the ageing process in the human body, and indeed it is well known that the disease is more frequent in the ageing than in the young. There is probably a good deal of substance in this idea, for it is difficult to believe that the elastic tissue of the arteries does not go through much the same changes as the elastic tissue of the skin. We have only to look at the faces of our colleagues to see the signs of ageing, from the fact that their skin becomes less elastic and their faces tend to slide towards their necks. Nevertheless, highly developed atherosclerosis can occur in quite young people, so that it seems right for the present to consider the arterial lesions as a real disorder of the tissues and not simply a result of ageing.

There is another possibility which is now being vigorously investigated, and which may be connected with the great increase of coronary thrombosis in recent times. This concerns the composition of the blood. It is sometimes supposed that thrombosis, the blocking of the blood vessels, is in all respects similar to the clotting of blood in the test tube. Nothing could be farther from the truth. Some eighty years ago small formed elements, much smaller than the red blood cells, and measuring some 2–3μ in diameter, were detected in shed blood; they are now known by the name of blood platelets. Normally, platelets circulate in the blood as discrete bodies, but a thrombus which is essentially an agglutination of platelets can be formed from flowing blood by deposition on the vessel wall. Afterwards, fibrin and blood cells such as the leucocytes and red cells collect in connexion with the platelets.

The electron microscope gives a very interesting and clear picture of the structure of platelets. They are found to consist of membrane-bounded material containing vesicles and granules, much like the cytoplasm of an ordinary cell, but without a nucleus. When agglutination occurs the platelets become closely applied to one another but the actual physical nature of their adhesion is unknown. It is certainly not due to dissolution of the platelets to form a structureless mass. The bounding membranes at least at the beginning of the process remain intact, though the granules are gradually discharged.

Platelets are now known to contain considerable amounts of adenosine triphosphate and it has recently been shown that adenosine diphosphate causes their agglutination. These observations have been carried one stage further, and it has been shown that adenosine monophosphate inhibits the agglutinating action of adenosine diphosphate. Investigations of the properties of the platelets by biochemical means correlated with observations in the electron microscope proceed apace, and it is conceivable that in a few years we shall have a clear picture of what happens during the interesting process of thrombus formation.

It would take me too far into the minutiæ of pathology to discuss the ways in which the production of thrombi may be linked at various stages with the changes which occur in the arterial wall, apart from the ultimate thrombus formation which may block the vessel. But I hope I have been able to show you how a chronic disease, of such widespread distribution that no one in this room is free from it, is being investigated by the accumulation of data from observations on man and his environment, by biochemical investigation on man where this is possible, on animals as a substitute for man, and *in vitro*. These investigations are coupled with the use of the most modern histological and microscopical techniques.

It is perhaps noteworthy that the greatest advances of medicine during the past century have been in the realm of infectious disease. These successes were based on the fundamental discoveries which were made by Pasteur, Koch and others of the relation of micro-organisms to disease processes. Many chronic diseases, of which arterial disease is one, have not as yet been shown to have any comparable unifying thread to connect them. They are at the stage of examination by the collection of data from whatever source they can be gleaned. If in the future a clear picture of what happens during the development of arterial disease is obtained, I hope that the person who records the last observations will not be credited with making a 'break-through'. We hear too much of 'break-throughs' in these days, for in my opinion such language tends to obscure the fact that all of us depend on the work of our predecessors. This to my mind is nowhere more clearly demonstrable than in the steps that lead to the elucidation of the complicated changes of pathological processes.

EDUCATION OF A SCIENTIST*

By SIR CHRISTOPHER INGOLD, F.R.S.

LANCASTER is to have its own university, and is thus to become one of the nurseries of the country's future leaders. So, Lancaster will soon be wrestling with the strategic problems of higher education; and, less bound by the chains of tradition even than universities established only a few decades ago, it will be taking, not just a part, but also, in its early freedom (which it will never get twice), a pioneering part, in the desperately urgent task of adapting our approach to higher education to the rapidly changing times, in fact, to the present scientific revolution. This is a matter in which the Lancastrian Frankland Society is bound to interest itself.

I have referred to the contemporary 'scientific revolution', a terminology which compares it, by implication, with the mechanical revolution of 150 years ago. In his *Outline of History*, H. G. Wells declares that Napoleon, despite the great space given to him in history books, had no permanent effect on history, comparable with that of, say, James Watt and other pioneers of the mechanical revolution, whose work transformed industry and changed the whole character of life in all civilized countries, permanently. It seems clear that the present scientific revolution will prove as lasting, and as profound. Already, though it is yet young, we see it contracting the world, transforming war, deeply affecting international relations, accelerating social change in developed and in developing countries, pervading industry and hence the economic foundations of civilized life, and modifying almost everything—what we eat, wear, and do—in our daily lives. All this has happened at a tremendous speed, all within the past forty years, and mostly within the past twenty. The massiveness of this uprush of science and its applications, and the suddenness with which it has gathered momentum, are well brought home to one in the computation that 90 per cent of the scientists who have lived since the world began are alive to-day.

So the scientific revolution is with us, and we have had plenty of time to recognize it. What then should be our correspondingly adjusted attitude towards education, in particular, towards the critical matter of the balance of the educational disciplines? I think that everybody knows the answer, though some may be more willing to express it than others. In any event, my answer is that, while all the well-trodden paths of learning are desirable vehicles of education, and are deserving of devotees, the classics, modern letters, and the sciences, education in science is in a class apart. It is not only desirable, as a part of modern culture; it is also essential, much of it for those few on whose foresight our future will depend, much of it for the many whose scientific work will build our future, and some of it for everyone who would comprehend something of the world in which he has to live.

Some science for everyone! If there was ever any health in what has for so long been accepted as the two cultures, there is none now. Reconsideration of our educational methods is overdue.

The reconsideration must begin at school. Our traditional schools have done more directly than any other national institution to create and maintain the two cultures, through the specialization allowed, and even enforced, by their division into 'sides', of which at least one, often one to which a special prestige is supposed to attach, is innocent of science. The Russians, more realistic, and less fettered by tradition than we are, have not made that mistake. Throughout the U.S.S.R., there is universal education to the age of eighteen, though at the age of fifteen the less academically minded children are transferred for their last three years to academically easier, more or less vocationally slanted schools, so that only a proportion of the original intake remains for those last three years in the essentially academic schools. But even before this parting of the ways, already at the age of thirteen every Soviet boy and girl that is born into this world alive starts physics; and at the age of fourteen, every one of them starts chemistry. In the academic schools, beyond the age of fifteen, these foundation subjects of science are continued, as is mathematics, a modern non-Slavonic language, and, of course, literature and history; and some optional extras may be taken or continued. So in the U.S.S.R., you can start a conversation on a scientific subject, let us say, for example, on the photochemistry of the upper atmosphere (the Russians are interested in the upper atmosphere), with a not-too-old stranger in the street, as you could not in England, with a fair certainty that you will be understood, and that he on his part will be well able to discuss the matter. I assert that no one in England to-day should be let out of a secondary or grammar school without a comparable introduction to physics and chemistry. These foundation subjects of science should rank among the foundation subjects of everyone's general schooling.

---

* Substance of the Eighth Frankland Oration, delivered to the Lancastrian Frankland Society, Lancaster, on October 19.

My education in school and university occurred fifty years ago. I read science from firm choice. More prestige was attached to modern letters, and more still to classics. No one then, that is, around 1910, had the remotest inkling of the impending uprush of science, or of the reversals of esteem that would inevitably follow.

Next to science itself, modern languages have gained in importance from the upsurge of science. The world is so contracted, and the need to develop a sense of commonweal has become so urgent, that language barriers are a danger: we all (not just a few of us) must read, understand, and talk with our neighbours, only a few hours' flight away. Therefore, the learning, in England, of modern languages, at least two, should be a primary school study, to be commenced at ages eight and nine, as it is in a number of European countries. Intelligent parents well understand that, at such ages, the first steps in a new language can be absorbed with a sense of fun, though a few years later, competing deeper intellectual interests will reduce them to drudgery. But if any new means of communication can be established in rudimentary form while the fun of it lasts, then its use and development in the grammar school could create interests comparably deeper with those of concurrent studies.

In proposing the inclusion of sciences and of more modern languages among the foundation subjects of general education, I am, of course, asking for substantially less specialization in the schools. Now you know the answer of the schools: each schoolmaster says in effect: "If my school did not specialize, the universities would prefer the pupils of another school that did, because its pupils would have more to show in the particular subjects they would propose for study in the university". I think that this argument is unanswerable, except by a complementary policy, covering the transition from school to university, and concerned with that much-neglected process, the conversion of the school child into the university student. I want to deal with that conversion last, and, before doing so, to look at its end-result, the university student, who we will accordingly, for the present, suppose has somehow become habilitated to his new situation. Let us then look at his situation, in particular, the kind of training he will thenceforth be receiving. This is the stage at which the various fields of study, science, letters, and so on, diverge, and a choice has to be made. Accordingly, I shall, from this point on, follow the course of university education in science.

At this level, there are two ways of presenting the subject-matter of science, namely, with the spirit of science, or without it. The matter with the spirit, I shall, for short, because I have much to say on it, call 'live' science, and the matter without the spirit, 'dead' science: the simile will be clear. If you want to make a scientist, you need to teach him 'live' science, because he has first to feel, and eventually to absorb, the spirit of science.

That spirit may be defined as the urge to disclose the ever-marvellous truth around us—*ever* marvellous, because it is dynamic, changing always as approaches are pressed or broadened, and, as we conceive it, subject to change unceasing, as new wonders disclose themselves. The university lecturer in science who cannot send out that signal had better give up. But the spirit I have just defined is the spirit which impels scientific research. That is why 'live' science teaching, the only kind that can build the next generation of scientists, must be done by research workers.

I may see this myself with a special clarity because of an experience of fifty years ago, which can be told now, as I am the sole survivor among the actors concerned. At school, I enjoyed both physics and chemistry, but physics distinctly the more. At college, I studied both with equal emphasis for a considerable time. I was taught physics by expert and devoted teachers, totally dedicated to the pedagogy of physics, and asking no reward higher than the excellent examination results that most of their pupils obtained. These teachers presented physics as a system of exact laws, which one had only to learn to apply. It was so tidy that one could scarcely go wrong. I did particularly well in my examinations, and my teachers could not understand why I elected thereafter not to specialize in physics. However, as I saw the matter, physics was tidy, but dead. Lord Kelvin had finished physics. So what could one do ? One cannot live with a corpse, however tidy. The mysteries that Planck and Einstein had already touched on even at that time, that is, around 1910, were never put before me; you see, they were not required in the examination.

I was taught chemistry by research workers, whose approach was very different. One in particular, D. R. Boyd, a brilliant teacher, made us from the outset feel that we were partners with him in an attempt to understand what we could of how Nature worked. He presented his science strictly fairly, strictly truthfully, including its imperfections, never over-simplifying, never glossing over obscurities, distinguishing sharply between what was known, what might be surmised, what was dubious and what was completely mysterious, giving reasons. He would summarize complicated factual situations with a skill that made reception painless—the skill of a barrister that he was in fact qualified to be, though he had never practised at the bar, but had become a professor of chemistry instead. So, by example, he taught us the arts of judgment, of scientific appraisal, of assessing possible significance, of scientific insight; and he showed us how continually one has to exercise these mature qualities of thought in a 'living' science. The frontiers of knowledge are never far away in any science, and he revealed them to us constantly, sometimes explaining how a sector had recently been pushed back, or pointing out what needed to be done to push it back. Obviously, chemistry was alive, pregnant with advance and adventure, unfolding on all sides in new revelations and new mysteries. I did not get such good examination results in chemistry. But what did that matter ? I did receive the spirit of science, and so, for that much better reason, I elected to specialize in chemistry.

That reminiscence, which I hope you will excuse, will serve to illustrate the first three major points that I want to make about university science, namely, the sharp contrast between 'live' and 'dead' science teaching, the intimate mixing by compulsive common motivation of the former with research, and the absolute necessity for 'live' science in the training of scientists.

One does still hear teaching and research set in contrast; but that is only the hang-over from an exploded, but formerly hard-worked, though never very credible defence of the university teacher who takes 52 weeks' salary for 30 weeks' part-time work. "Some are born researchers, others are born teachers, and we need both"—so the argument ran. We in universities know just what that is worth, but the educated general public, including even some civil servants, seem not to. I recently read an official paper in which occurred the phrase, "the balance between teaching and research": and the context showed that "balance" meant balance. A no-doubt carefully educated civil servant, writing on university education (so you would expect him to know something about it), obviously did not know the first thing about university education in science. He did not know that live science teaching and research are intrinsically inseparable, and therefore cannot possibly be weighed or balanced one against the other. The rule in science is that the best researchers are the best teachers. Nearly always, they are the keenest teachers, and always, they are the most inspiring. Remember, these researcher-teachers are the individuals on whom we are wholly dependent for the production of the next generation of scientists.

A side-deduction from this is that we should not as a nation set up research institutes covering any of the main subjects of formal instruction to science students. For such institutes do not take care of the scientific succession: they sequester the men who should, by influence and example, be pointing the way to the next generation of scientists in their formative years. Research institutes of more specialized types are, of course, in quite a different case. I think that Britain is broadly sound in its policy on this matter. I could not say the same of all countries.

I might, perhaps, here slip in the explanation that my remarks on science have no concern with mathematics, which is not a science, until so applied, but is intrinsically a technique of thought, highly interesting it itself, and indispensable to many scientific, and to certain other, disciplines.

Let us now return after these digressions to our science student. Let us assume that he has been exposed for some years to 'live' science teaching (such as I had in chemistry), with the result that he well understands that science is a dynamic unfolding, and that, in that light, his interest, indeed his dedication, stands confirmed. Let us assume also that he has acquired some scientific background knowledge; how much, his bachelor's degree will show, though he will have to learn more afterwards. Finally, let us assume that he is beginning to build up a capacity for scientific judgment. All that is still not enough: he has to have technique. This involves going under a master for several years of research under personal guidance, at least to the stage which is usually marked by a doctor's degree. Some of those who eventually go farthest take an additional period of research under partial and relaxing guidance, before they consider themselves competent scientists.

Why is this apprenticeship so long ? Why does it depend on one master after another ? The answer lies essentially in the great difficulty and complexity of modern science. The arts are in a different case. The man of letters is usually self-made, and his work is strictly individual. A historian gathers scattered information, writes his book, and launches himself: he does not have to be launched by another historian. But every scientist comes out of a scientist: no modern scientist could launch himself unaided. One could write many scientific genealogies, reminiscent of the "begat" lists in the Old Testament.

Let us further consider the environment in which our scientist-to-be finds himself during this last phase of his training. Conditioned by the complexity of modern science, it is an environment of elaborate organization. Times have changed since the turn of the century when the Curies went into a dilapidated back-shed for four years, and with shovels, buckets, stone jars and beakers, isolated radium. To-day, techniques are enormously more powerful, but also enormously more complicated, diversified, and specialized. The first result of this is that even the scientific master can to-day do nothing by himself: he does not know enough: he is not skilful enough. He must enter, or gather around himself, and, with his students, work within, an organization of other scientists and technicians, having knowledge and skills complementary to his own. That is why scientists work in groups, in which constant mutual help is the tacit rule of life, and scientific cross-fertilization is accordingly universal and continuous. Scientific success goes to the strong groups, those that make themselves strong by thus harmoniously and intimately combining a maximum of complementary intellectual endowments and interests.

I hope that the new University of Lancaster will remember this when planning its scientific faculties. Science should be organized in the largest administratively feasible units. 'Little Kingdoms' are a source of weakness; and any eliminable internal frontier is a source of both weakness and waste.

I have so far discussed the situation of our potential scientist, first, as the schoolboy with science as one possibility before him, and then, later in his career, as the fully dedicated science student. I want now to fill the gap, that is, to consider his transition from the first of these two states of life to the second. Two problems are involved, one of adaptation, and one of selection; and they are closely interlinked.

Throughout most of the life of the schoolboy, the teaching to which he is exposed is necessarily of an *ex cathedra* character, and his attitude towards it is necessarily one of reasonably disciplined receptivity. He accepts his lessons as authoritative, does the prescribed homework, learns what he is told to learn, and practises the techniques in which he has been instructed.

In a university, the conditions of education are very different. The method is that of guided self-tuition. You are assumed to be a student; and receptivity will not make you one. A student must be purposefully such, with self-motivated, self-organized habits of study, and with an already mastered technique of self-tuition. He must learn in that way, with no more than general guidance, what can be gained from books. The lectures, which, as a science student, he will attend, will be directed fundamentally to the development of scientific judgment and scientific insight, things that cannot be obtained from books.

Now the adjustment of attitude required to convert the receptive schoolboy into the independently purposeful and self-organized student is profound. A new technique of learning has to be acquired. It must take time. In my opinion, a year would not be too long to allow. In general it cannot be done in universities, in which, as most are now organized, there is no spare time.

I was fortunate fifty years ago. In my last year at school I had no formal science lessons at all, though I received invaluable help from the masters. But I composed my own lessons, and prescribed my own home-work, with no more than general guidance from them. So my schoolmasters taught me the first of all academic lessons—that of how to learn: and when I later walked into a university, and was automatically treated as a fully re-adjusted student, I was one.

In the very best schools to-day, the method of work in the sixth forms is almost exclusively that of guided self-tuition. The boys that come out from these forms are students, ready for university education. But such schools are not in the majority. In most schools the children are lessoned and coached to the bitter end. When these pupils gain entry to universities, as they do in large numbers, they go in completely unadjusted, lost souls in an uncomprehended world. Only the toughest will survive unharmed. The rest will leave, some sooner, some later, all with more or less blemished records, which may never have been blemished before. It would have been better for them not to come. They constitute the main part of what is called 'student wastage': and it may not be because anything is wrong with them. Rather, it will be because they never had a fair start. They began with a handicap, from which it is extremely difficult to recover. 'Student wastage' is a term which summarizes severe discouragement to many young persons at the start of their careers, to more, indeed, than statistical returns plainly show, because the grievousness of 'wastage' is recognized, and so it is concealed as much as possible.

It is, of course, the competition for university places that creates this situation. Only the very best schools can rise above it, that is, refuse, despite parental pressure, to push into universities those of their pupils who could not get there with no more than general guidance. The fact is that many more of our population aspire to university education than have any notion of the severity of its rigours, or are constitutionally suited to withstand them.

So, between school and university, selection has to be applied. Great effort is expended in universities in trying to do this job well, that is, so to select as to eliminate 'student wastage'. Actually, the job is done badly: 'wastage' continues. The reason is that any properly acceptable candidate should satisfy on all of three criteria, on two of which one can, at the time of selection, get no information. The criteria concern academic attitude as just discussed, native capacity, and acquired information. Only the last of these three requisites has a yard-stick, that of examinations, which in fact jointly measure the pupil and his schoolmaster in some unknown proportion, and hence give no clue to capacity, or to attitude. Remember that the applicants for any one university come from all over the country, and that it is therefore quite impossible for the admitting officers adequately to know all the schools. As to interviews let me speak for myself, and say that I cannot assess either of the two vital imponderables on the basis of a half-hour interview. Most of the candidates know the right things to say, and those that do not may well do themselves less than justice. But a decision has to be made; and so, after trying everything, one comes back to the only, though woefully inadequate, yard-stick, and, more often than not, decides accordingly, with not much better than even chances of being right.

I think that there is an answer to this double problem of adaptation and selection. It is to shift the moment of selection from where it is now, between school and university, to one year after entry into the university. This partly resembles what is done in Scotland, and it is what is done in Australia. The university runs a first, relatively unselected, propaedeutic year, and then, after selection, three following years leading to an honours degree. The original acceptance is based purely on a school-leaving examination, and it commits the university for no longer than one year, at the end of which selection is applied. Under this system, anyone with a reasonably good school record, who wants a year in a university, can have one; and so many will get no more that no stigma attaches to the shortness of the period. Those short-term students will consolidate, and somewhat enlarge, their school knowledge; and, what is more important, they will gain some independence, and capacity for responsibility. But those who will be kept on to read for a degree will have this preliminary year, in which with help of staff, to lose their school attitudes, to habilitate themselves as students, and hence, if they are science students, to fit themselves to feel as partners with those under whose influence they will come in the three subsequent years. For its part, the university will have the year in which to find out all it needs to know for the purpose of rational selection.

There would be no sense in minimizing the operational size of this proposal. It means new university buildings, and new staff. The propaedeutic year, with its large numbers, and very special pedagogic objectives, quite different from those of university education as generally understood in England, could not, in science at least (and science is all I can speak for), be run by the same people as take care of the subsequent years. In any science subject, the territory, equipment, staff and form of organization of the propaedeutic year, would have to be distinct. Exactly how this is arranged is less important, but not unimportant. One way would be to leave the first-year organization in any subject as a 'junior branch' of the relevant department. Another way would be to put together the first-year organizations of all subjects, and call the result a college of the university. I think myself that the latter kind of arrangement might well turn out to be the happier.

In conclusion, let me recapitulate, now in chronological sequence, the changes in education which I think necessary in order to produce citizens adapted to the scientific age, and, in particular, to create the scientists themselves. I should like to see at least two modern foreign languages started in the primary schools, and kept up in the continuation schools. I should like to see substantially less specialization in the grammar schools, with physics and chemistry, the foundation subjects of science, made foundation subjects, in secondary and grammar schools, of everyone's general education. I should like to see the burden of competing for university places taken from the schools, and the burden of selecting on inadequate data taken from the universities, by a shift in the time of selection to one year after entry to universities on the basis of a paper requirement only. To provide for this large, relatively unselected, preliminary year would involve special organization and substantial expansion in most English universities, changes equivalent to the adding of a college to each university. During that year, the main pedagogic objective would be to produce fully habilitated students; and the main administrative objective would be to assess their potentialities as students, their intrinsic capacity, and their depth of interest, and so to select them rationally. From then on, our selected scientist-to-be must be exposed to the living spirit of science. He must become partner from the outset with his research-teachers. As he matures in the succeeding years, his share of responsibility in the partnership will grow, until, indeed, in some cases, the final responsibility becomes wholly his. Thus will the next generation of scientists be created.

I have dealt only with general national policy, which must, I think, constitute one's first approximation to the subject. The second approximation would involve detail, less well suited to a discourse such as this. It would consist in a discussion of those variations from general policy which would be necessary to accommodate the conditions in a minority of particular universities, colleges and schools. But as long as the general policy is so far from being nationally agreed, there is no sense in raising these more particular questions. Yet it is worth while now to note the general point that the variety in the English educational scene is such that one must be prepared to apply special treatment to outstanding special cases.

THE NATIONAL LENDING LIBRARY FOR SCIENCE AND TECHNOLOGY

By DR. D. J. URQUHART
Director

IN November 1956 the Research Council of the Department of Scientific and Industrial Research decided that the planning of a new national science lending library should begin. On November 5, 1962, the National Lending Library for Science and Technology was opened by the Minister for Science, Lord Hailsham, at Boston Spa in the West Riding of Yorkshire (see also p. 1019). Such in brief is the history of the Library. Its 'pre-history' includes the efforts of S. C. Bradford in the 1920's to expand the Science Museum Library and to start a national loan service. The 'pre-history' also includes discussions at the Royal Society Scientific Information Conference in 1948 and within the Advisory Council on Scientific Policy and its Library Committee.

The essential purpose of the new Library is to ensure that the practising scientists and technologists in the United Kingdom can obtain quickly whatever scientific literature they may need. The need for such an organization was underlined by the observation in 1956 that only half the Russian scientific literature which the Russians thought worth while abstracting was reaching Britain at all[1]. The reason for this was quite simply that there was no organization specifically charged to prevent this sort of situation arising.

Planning

The outline plans for the National Lending Library were prepared in 1957 by assembling the available data about the demand and output of scientific literature. A great deal of this information was obtained by treating the Science Museum Library as the prototype for the new Library and examining its experience[1-3]. The plans evolved envisaged establishing in 1962 a library which would receive then about double the volume of current literature which the Science Museum Library was receiving in 1956. The year 1962 was chosen only because it was thought in 1957 that the Science Museum Library might have a new building in 1962. The need to link the rate of development of the new library to possible developments in South Kensington arose because it was proposed that part of the stock of the Science Museum Library should be transferred to the National Lending Library.

The preliminary surveys[1] suggested that the Library might have to hold something of the order of 15,000,000 volumes in a hundred years' time, and that then the world's output of scientific literature might be about half a million volumes a year. These figures were obtained by extrapolation from the existing situation, assuming there was a finite limit to the creative capacity of a population of a given size.

In opening the Library, Lord Hailsham observed that this estimate was "almost certainly wrong as extrapolation—the process whereby these figures have been obtained—is the only thoroughly unscientific habit in which professional scientists habitually indulge". So far the only use made of these estimates was to specify that the Library would need a large site. The only other essential requirements regarding the site was that it should have access to postal facilities which would make a "by return of post" service possible.

The search for a site took place in 1958. It revealed that a suitable site with some industrial buildings on it existed in part of the Royal Ordnance Filling Factory at Thorp Arch, Boston Spa, Yorkshire, which was then going out of production. As it was found that it would be possible to adapt the buildings economically to house the Library, this site was accepted. The buildings taken over by the Library were single-story buildings with a floor area of about 130,000 square feet. The adapted buildings came into use in 1961. The only building work on new foundations required was a boiler house and two linking corridors. By the bold use of colour the original nature of the buildings has been successfully disguised. In opening the new Library, Lord Hailsham said: "It is, of course, a filling factory, and nothing could be more appropriate than to fill it with books instead of explosives; nothing is more explosive than books unless it be science or technology. It is, however, nicer than the New Bodleian in appearance, and by using the old buildings we got it cheaply, and by acquiring the old site we got it more quickly than might have been the case otherwise".

Stock

At present the library is receiving about 12,000 current serials and a further 10,000 are on order. The aim is to have all the recent scientific and technological serials published in the world which are, or perhaps should be, abstracted. The subjects covered include all branches of science and technology including agriculture and medicine. Books, as distinct from serials, form only about 10 per cent of the collection, and consist mainly of Russian books published since 1957 and English-language books published since 1960. In all, the Library contains about 350,000 volumes. This figure has been estimated from the fact that about 700 tons of literature have been moved to Boston Spa, the great majority of it from London.

The Library only collects microforms where material is not available in the original size, but it has a collection of about 125 miles of microfilm. This consists mainly of copies of the report literature issued by the U.S. Office of Technical Services and copies of *ad hoc* translations prepared in the United States of articles in Russian scientific literature.

The Library stock consists, in roughly equal parts, of : (*a*) literature which has been obtained by the National Lending Library by purchase or exchange ; (*b*) literature which was transferred to it from the Science Museum Library ; (*c*) literature which has been presented to the Library by other libraries. The flow of literature from other libraries to the National Lending Library started as a result of an invitation to libraries to transfer to it, on economic grounds, volumes which were not heavily used in the holding libraries, on the basis that the literature could always be borrowed rapidly if it was required. This appeal produced serial literature from a large number of libraries. This flow of literature is continuing, and it is proving very useful in extending backward some of the serial holdings of the Library and in duplicating more frequently used titles. For by a strange chance most copies are received of the most heavily used titles. This result was unsuspected when the appeal for literature was first launched; but it is directly related to the observation that the serial titles which were found to be most heavily used in the Science Museum Library were those which were most widely held in Britain[3].

Service

The Library only lends to organizations on an approved list of borrowers : these include universities, colleges, research organizations, Government departments and industrial firms as well as a small number of public libraries. It uses special loan request forms which cost £3 a pad of 50—the price is intended to cover the average cost of postage arising from 50 requisitions. The aim of the Library is to deal with all straightforward loan requests the day they are received, and as a rule this target is achieved.

To facilitate the use of letter post in dispatching loans the parts of about 1,500 of the most frequently used serials are bound in a light flexible binding as soon as they are received. Even where buckram binding is used publishers' volumes are split if possible to produce small volumes[4]. At present the Library is able to satisfy 75 per cent of the loan requests it receives from its own stock. Some of the requests for items not available at the National Lending Library are sent to the Science Museum Library, where that Library is likely to be able to satisfy them.

In addition to its loan service the library maintains a public reading room and it has a photocopying service. The facilities available at the Library are described in a brochure[5].

Library Techniques

The techniques used in the Library are somewhat unusual. This is partly due to the fact that the main task of the Library is to be a library for libraries, and few libraries have this problem. It is also partly due to the fact that the initial planning section consisted of three officers who had each been trained in physics and some procedures have been adopted after deliberate experiments. In developing internal procedures the aim has been to cut down records to a minimum and to obtain a maximum amount of literature with the available staff. There is, for example, no record in the Library which is called 'the catalogue'. The literature is arranged on the shelves according to its titles, and it is only possible to say whether a particular publication is available by consulting the shelves. This system permits the rapid issue of the majority of items requested, as they can be found on the shelves without consulting any records[6]. As a result of this approach to techniques Lord Hailsham said in opening the Library: "In many ways this Library breaks away from current library practice. The fact that this break has taken place in the field of scientific literature, and that the planning of the Library has been done by scientists, and that the senior staff of the Library is composed of science graduates has, of course, largely determined the form which these particular innovations have taken. But it would be a mistake to suppose that the creation of this great National Lending Library for Science and Technology would have no repercussions in other fields affecting libraries of other kinds".

Promoting the Use of Scientific Literature

In addition to being concerned with collecting and supplying literature, the Library hopes to contribute to the study of the flow of scientific information. In 1963 the Library proposes to carry out a survey of the use of serial literature. Besides using the results for administrative purposes such as deciding where duplicating is necessary or what the binding policy should be, it is proposed to study the existing system in the English-speaking world for making known the contents of serials which have not been used. It is hoped that this may throw some light on the efficiency of the present arrangements for making information available. It may, for example, reveal the relative importance of such factors as the inadequate coverage of abstract publications or the lack of awareness among potential users of how to use the guides to the literature of science.

This last factor has already been the subject of a small experiment. During September 1962 eight research students holding Department of Scientific and Industrial Research awards were invited to attend a four-week course at the Library on the use of scientific literature. The preliminary results indicate that formal training in this subject might usefully receive more attention than at present.

It is hoped that the survey on the non-use of literature may indicate which of the possible ways of improving the existing channels, which link the producer of scientific literature to the consumer, should receive priority. The survey may also indicate how important it is to develop entirely new channels based on computors. A useful computor would be one capable of reading types in all languages, analysing, translating and selecting. At the moment the input required is about ten million words a day and at present this is expanding exponentially.

The National Lending Library hopes to keep the possibility of such developments in mind and to act as a centre for innovations in the fields of librarianship and documentation. Such innovations are not only necessary in the field of scientific literature. As Lord Hailsham said: "Science and technology form, of course, the field in which the corpus of human knowledge is growing at the most rapid rate, and the need for adequate documentation, classification and bibliography is therefore greater in this field than anywhere else. But it is not the only field. The time has for a long time been ripe for technical and organizational advances in other library fields. The existence of this great new step in the field of libraries—perhaps the most important in this country ever to have been made since the foundation of the British Museum Library—embodying as it does so much scientific planning and so many revolutionary new techniques and conceptions, cannot fail to have a profound and increasing influence on libraries and librarianship generally".

CLOSURE OF THE *MERLIN* RESEARCH REACTOR

MERLIN[1] was the first, and may well be the last, industrial research reactor in the United Kingdom. It was made critical for the first time on July 16, 1959, and was officially opened by H.R.H. Prince Philip, Duke of Edinburgh, in November 1959. It achieved its full design power of 5 MW in 1961 and ceased operating on August 31, 1962. During its period of operation the reactor went divergent 675 times and about four hundred separate irradiations were performed. *Merlin* will be maintained so that it can be used again if the need for reactor irradiations increases significantly in the future.

Before and during the initial period of operations the following studies were started and techniques developed: (*a*) Sub-critical studies of different arrangements of reactor cores. (*b*) Safety studies, especially the effects of reactor power transients, and of heating by radiation experimental materials placed in the reactor. (*c*) The proving trials of the reactor. (*d*) The measurement of radiation fluxes and doses. (*e*) Fission product detection. (*f*) Reactor chemistry. (*g*) Effluent measurements and disposal.

Following these initial projects the main research programme had begun to produce significant results. Shielding studies for gas-cooled, graphite-moderated power reactors were carried out on assemblies simulating various portions of such a reactor. This was done in a *Merlin* thermal column with the graphite removed to provide a large volume, about 4 ft. × 4 ft. × 6 ft. deep, for irradiations. These investigations included measurements of the neutron distributions above a simulated reactor top-reflector where streaming along the fuel channels produces large perturbations in the distribution. The results were used for providing a computer programme for the estimation of such distributions in practical power reactors. The boiler shield design for one of the new power stations was checked, as was the attenuation produced by the complicated ducting for the coolant at the top of the boiler shield. The thermal column was also used to determine the fine structure of the thermal neutron flux in a fuel element of a new shape for future gas-cooled reactors. In order to obtain as much information as possible from such measurements the spectra of the neutrons have been characterized by means of the reaction-rates of various threshold detectors.

Another field in which it was useful to obtain information on the neutron spectra was that of radiation damage research. Investigations were made, under contract to the U.K. Atomic Energy Authority, of the basic mechanisms of radiation damage to fuel materials such as uranium oxide. Radiation damage to materials such as zirconium was also being investigated, as was the effects of radiation on the corrosion of these materials. Materials were also investigated, with regard to their impurity content, using activation analysis. These materials were of two types, those to be used in reactors and those of interest as semiconductors. A fast transfer unit was built which could transfer a sample from the centre of the reactor core to a nearby radiochemistry laboratory in about 5 sec. The research in this field was aimed at minimizing the time of any necessary chemical procedures after irradiation so that analyses, as well as the irradiation, could be carried out rapidly. Since the neutron flux at the centre of the core was high, 5×10^{13} thermal neutrons/cm^2, the sensitivity was also high.

A single-crystal neutron spectrometer was built in the Laboratory. Its operation is fully automatic; the counting-rates of the various detectors are recorded on magnetic tape. The spectrometer was to be used initially for investigations of neutron capture γ-radiation; it could also be adapted for neutron diffraction experiments. In the short time in which the spectrometer was in use the spectra of neutrons from the experimental tube was determined and the variation of the gold absorption cross-section as a function of neutron energy was measured to check the operation of the instrument.

The reactor has also been used for training personnel in reactor operations and in providing experience in reactor research. Engineers came for training from associated companies in the United Kingdom, and also from Canada, Italy, Germany, Greece and the Netherlands. Scientists came for experience from the Imperial College of Science and Technology, and Queen Mary College, London, the Universities of Birmingham and Southampton and from Greece and South Africa.

The reason for closing the facility is the present economic position of the electrical industry in general and of the nuclear power industry in particular. The heavy losses in the latter field have had their effect on the amount of money which industry is prepared to invest in long-term research on nuclear power. Reactors are relatively expensive items of research equipment, and to use them to economic advantage they ought to operate almost continuously: indeed, for many experiments continuous irradiation is essential to avoid relaxation of the effects produced.

To justify such continuous operation many more experiments were necessary and these were being discussed with the National Institute for Research in Nuclear Science on behalf of several universities, and with other bodies with the view of operating continuously from 3–5 MW starting at some date in 1963. Unfortunately, the climate in the whole of the atomic energy field deteriorated rapidly, and in view of the grave uncertainty over external contracts it was decided that the reactor should be closed down.

T. E. ALLIBONE

OBITUARY

Prof. Niels Bohr, For.Mem.R.S.

BY the death, on November 18, of Niels Bohr we have lost the most distinguished physicist of our time, the founder of the quantum theory of atomic structure, a natural philosopher whose profound insight enabled us to understand the complementary dual behaviour of atomic objects and who was a pioneer in explaining the internal behaviour of atomic nuclei.

Niels Bohr was born on October 7, 1885, the eldest son of Christian Bohr, professor of physiology in the University of Copenhagen. In his youth both he and his brother, Harald Bohr, the mathematician, were expert footballers. After taking his doctorate in 1911 he went to the Cavendish Laboratory at the time J. J. Thomson was putting forward his "plum pudding model" of atomic structure—a sphere with positive electricity distributed uniformly with electrons embedded in it. From the Cavendish, Bohr moved in 1912 to work for a few months with Rutherford, who in the previous year had published his theory of the nuclear atom. The difficulty of the theory was to understand why the electrons did not fall into the nucleus, and Bohr's profound contribution was to quantize the orbits of the electrons and, in particular, to show how the line spectra of hydrogen could be explained by quantized transitions between orbits. Rutherford's first reaction in March 1913 was to write, "Your ideas as to the mode of origin of spectra in hydrogen are very ingenious and seem to work out well; but the mixture of Planck's ideas with the old mechanics makes it very difficult to form a physical idea of what is the basis of it all". Bohr's ideas also explained how the physical and chemical properties of every element could be based on the atomic number, the number of units of positive charge in the nucleus. From this it also became clear how the emission of α- and β-rays from heavy nuclei would shift the nucleus two places down or up in the Periodic Table.

At the meeting of the British Association in the autumn of 1913, Bohr's ideas were discussed, and according to Bohr, Jeans's introductory survey of the application of the quantum theory to the problems of atomic constitution was "the first public expression of serious interest in considerations which outside the Manchester group were generally received with scepticism".

During the autumn of 1914, Bohr returned to Manchester with his wife, Margrethe, to succeed Darwin as Schuster's reader in mathematical physics, and for a time worked with Makower on building apparatus to investigate phenomena in the Franck–Hertz experiments on quantum phenomena in the excitation of atoms. However, the fine quartz apparatus built by a German glass-blower was ruined in an accident, and Bohr soon afterwards returned to a new chair of theoretical physics in Copenhagen. In 1920 he was appointed the first director of the newly created Institute of Physics. The Bohr Institute soon became a magnet for theoretical physicists from many countries—his visitors and students included Kramers, Heisenberg, Pauli, Darwin, Dirac, Fowler, Hartree, Mott, Landau, Peierls, and many others who in turn became leaders in their own country. Of this period Bohr has said that "a unique co-operation of theoretical physicists from many countries created, step by step, a logically consistent generalization of classical mechanics and electro magnetism and has sometimes been described as the heroic age in quantum physics. Many obstacles had to be overcome before this goal was reached and time and time again progress was achieved by some of the youngest of us".

In May 1930 Bohr visited Cambridge to give in the Scott Lectures an account of his ideas on the complementary nature of different aspects of behaviour of 'atomic objects'. He discussed how the interaction between the 'atomic object' and the measuring tools prevented unambiguous answers as to whether the atomic object was a particle or a wave. Bohr was always difficult to hear and understand, and I had the difficult task of writing a verbatim account of his lecture and sending it to him to be used for publication.

In 1936 Bohr invented the liquid drop model of the nucleus, which was later to have great importance in understanding the phenomenon of fission and of the different modes of excitation of nuclei when disturbed.

When the fission of uranium by neutrons was discovered in January 1939 and the physical character of fission elucidated by the experiments of Frisch and Meitner, Bohr was on his way to Washington and took part in the discussions on the fission phenomena. By February he suggested in a letter to the *Physical Review* that it was mainly the isotope U-235 which was fissioned by slow neutrons, while the U-238 isotope would usually absorb the neutrons without fission. This led to the realization that the isotope separation of U-235 would be necessary to produce a fast chain reaction.

When Denmark was invaded in 1940, Bohr felt it his duty to remain there to protect the refugee scientists at his Institute. In the autumn of 1943, however, it became known that Hitler's policy towards the Danish Jews was to change and that Bohr, whose mother was of Jewish stock, was to be arrested. He and his wife and four sons escaped in small boats to Sweden. In accordance with a prearranged British plan, he was then flown on October 6, 1943, in a Royal Air Force *Mosquito* to Britain; failing to get oxygen, he was unconscious for most of the flight. His son Aage, who was also a physicist and was to act as his personal assistant, arrived a few days later. Bohr was welcomed by Chadwick and many friends, including myself. Chadwick was about to depart for the United States to resume co-operation with U.S. scientists on atomic energy.

Niels and Aage Bohr joined the British Group in December 1943, and Niels was known as Mr. Nicholas Baker and his son as Jim Baker. They were provided with guards by the Manhattan Project wherever they went in the United States. The guards turned out to be most useful in preventing Niels Bohr crossing the streets against the traffic lights. Bohr paid extensive visits to Los Alamos, where he took considerable interest in the theory and design of the atom bomb and acted as a father confessor or tranquillizer to the high-powered and sometimes temperamental physicists.

As soon as Bohr heard how far the development of the bomb had gone he was struck by the political implications. He saw it not only as a great threat to the world but also as a great opportunity to bring about a saner international order. He discussed this with Sir John Anderson, who was in charge of the British atomic energy project, and in May 1944 he had an unfruitful interview with Mr. Winston Churchill. Later, in August of that year, he obtained through Mr. Justice Frankfurter an interview with President Roosevelt and urged him to inform the Russians about the existence of the bomb though not the details, "in an effort to achieve international control and to head off a fateful arms race". Drs. Vannevar Bush and J. B. Conant were also thinking at this time about the establishment of an International Control Agency with Russian membership. When the President and Prime Minister met on September 18, 1944, they considered Bohr's suggestions but decided that the project should continue to have the utmost secrecy.

The idea of the international control of atomic energy was, however, pursued by Bush and Conant and led to the Acheson–Lilienthal proposals for international control, which in the end came to nothing in the face of Russian opposition in the United Nations.

In his later years Bohr continued to devote a great deal of thought to these problems and I have on several occasions walked round and round the grounds of his "House of Honour" at Gamle Carlsberg hearing about his discussions with Sir John Anderson and an account of his interviews with Sir Winston Churchill and President Roosevelt.

During this period Bohr was a founder member of CERN and took a great interest in its development. A meeting at his Institute decided what type of accelerator should be built, and the Theoretical Physics Group of CERN was first located in Copenhagen.

The 1962 Lindau Conference was saddened by Bohr's having a minor attack of the illness which finally led to his death.

Throughout his life Bohr was greatly helped by his wife, Margrethe, a daughter of the mathematician Prof. Norlund, who presided over the "House of Honour"—a hospitable house where innumerable Institute parties were held in the great conservatory with music and talk and barrels of Carlsberg beer provided by the science-loving brewery.

Bohr received the Nobel Prize in 1922 and was elected a Foreign Member of the Royal Society in 1926. He received the highest Danish honour of the Order of the Elephant and the Atoms for Peace Award in 1953.

We will remember him above all for his humanity and his great friendliness to, and encouragement of, young scientists. JOHN COCKCROFT

NEWS and VIEWS

Wykeham Professorship of Physics, Oxford: Prof. R. Peierls, C.B.E., F.R.S.

PROF. RUDOLF PEIERLS, professor of mathematical physics in the University of Birmingham, has been elected to the Wykeham professorship of physics in the University of Oxford, and will take up his new position in October 1963. He succeeds Prof. W. E. Lamb, jun., who has been appointed Ford professor of physics in Yale University. Prof. Peierls was born in Berlin in 1907, and received important parts of his education at the Universities of Berlin, Munich, Leipzig and the Technical High School in Zurich. When he went to Manchester as Research Fellow in 1933 he was already very well known for his pioneering researches on the quantum theory of thermal conductivity and other solid-state phenomena, and for his work with Landau on quantum electrodynamics. He was at the Mond Laboratory, Cambridge, during 1935–37, where important contributions to the theory of co-operative phenomena and nuclear reactions were made. Except for a period during the War when he was engaged on the atomic energy project in the United States, Peierls has been at Birmingham since 1937, first as professor of applied mathematics, and then as professor of mathematical physics. Under his guidance and stimulating leadership a very important school of theoretical physics has developed at Birmingham.

Peierls was awarded a C.B.E. in 1946 and was elected a Fellow of the Royal Society in 1945, receiving its Royal Medal in 1959. He is a member of the Governing Board of the National Institute for Research in Nuclear Science. Besides numerous research papers in many different branches of theoretical physics, Peierls has written two highly regarded books, *Quantum Theory of Solids* (1955) and *The Laws of Nature* (1956). His transfer to Oxford is a very favourable development for that University, where the activities in experimental physics cover a wide range, which, however, is fully matched by the breadth of the new professor's interests and talents.

Zoology at Edinburgh: Prof. J. M. Mitchison

DR. JOHN MURDOCH MITCHISON, at present reader in zoology in the University of Edinburgh, has been appointed to the chair of zoology at that University. This chair, which is in addition to the chair of natural history occupied by Prof. M. Swann, has not been filled since Prof. J. H. Ashworth was transferred in 1927 to the chair of natural history. The appointment will take effect from January 1. Dr. Mitchison's undergraduate career at Trinity College, Cambridge, was interrupted by war service spent in Army Operational Research, in which he attained the rank of major. Nevertheless, he added in 1946 a first-class honours in Part 2 of the Natural Science Tripos to the first-class honours in Part 1 which he had gained in 1941. He spent the period from 1947 until 1953 in research in the Department of Zoology at Cambridge, and was awarded the degree of Ph.D. in 1950. In the same year he was elected to a Prize fellowship in his own College, Trinity, which he held until his appointment to the Department of Zoology in Edinburgh in 1953. Dr. Mitchison has also accepted several invitations to pursue his research overseas. In particular, he worked as a research associate at the University of California, Berkeley, in 1957, while holding a Carnegie travel fellowship, and in 1960 he was appointed visiting professor at the Marine Biological Station, Wood's Hole. Throughout this period, Dr. Mitchison's principal research interest has lain in the field of cell biology.

British Committee on Chemical Education

Prof. R. A. Morton, professor of biochemistry in the University of Liverpool, has been appointed the first chairman of the new British Committee on Chemical Education, established jointly by the Royal Society and the Royal Institute of Chemistry. This Committee comprises nominees from the Royal Society, Royal Institute of Chemistry, Chemical Society, Society of Chemical Industry, Science Masters' Association, Association of Women Science Teachers, Ministry of Education and the Scottish Education Department, together with several persons who have been invited to serve in their personal capacity but with special reference to their experience in diverse fields of chemical education. The secretary of the Committee is Mr. D. G. Chisman, Education Officer, Royal Institute of Chemistry, 30 Russell Square, London, W.C.1. One of the main functions of the new Committee will be to co-ordinate and make more widely known the various developments that are taking place in chemical education and generally to disseminate information on what is happening in different spheres of chemical education in Britain and overseas.

At the first meeting of the British Committee, preliminary consideration was given to the function of examinations in chemistry at school-level, especially in the light of the new approach to the teaching of chemistry that is being developed as part of the project for the improvement of school science and mathematics curricula, sponsored by the Nuffield Foundation. The desirability of ensuring that questions set in public examinations are in harmony with the new approach to the teaching of chemistry was stressed, and to this end the Committee hopes to establish co-operation and sympathy with the General Certificate of Education Examining Boards, many of whom are known to be revising their chemistry syllabuses at the present time.

Atomic Energy at Capenhurst and Aldermaston

In an adjournment debate in the House of Commons on November 19 on the Atomic Energy Establishment, Capenhurst, the Parliamentary Secretary for Science, Mr. D. Freeth, repeated his previous assurance that the reduction of output to the minimum level to keep the plant in production was being effected by a phased process over about 18 months. The level of activity at Aldermaston was unlikely to change significantly over the next 18 months or so.

Commonwealth Scholarships and Bursaries

In a written answer for the Secretary for Technical Co-operation in the House of Commons on November 22, Mr. Iain Macleod stated that attendance at the introduction courses for overseas students arranged each autumn by the British Council, including special courses in London for Commonwealth scholars and bursars, had doubled within the past three years. The Council encouraged institutions of higher education to arrange their own courses and would do all it could in co-operation with the educational authorities to extend this work. Under the Commonwealth Teacher Training Bursary Scheme, Britain had awarded 97 bursaries leading to a technical teacher qualification, and 54 bursars had completed their courses. Under a new scheme announced at the second Commonwealth Education Conference, 40–50 bursaries would be awarded annually for teachers of craft subjects, students attending a technical college for six months, and after six months practical training in industry, spending a second year in a technical teacher training college. The first intake of bursars would be offered courses in mechanical engineering, electrical engineering, constructional engineering and building. Every encouragement was being given to postgraduate scholars in science and technology to take advantage of part-time teacher training courses.

The U.S. National Science Foundation

An admirably illustrated brochure recently issued describes briefly but clearly the many-sided activities of the National Science Foundation (*National Science Foundation.* Pp. 32. Washington, D.C.: National Science Foundation, 1962). The way in which the Foundation supports research, its varied programmes in support of education in the sciences, its work in the field of scientific information, in assessing the potential and need for national research and its support for international scientific activities are summarized. Included also are an outline of the organization of the Foundation and a brief list of publications giving further information on particular activities.

Scientific Research in Schools

The fifth annual report of the Royal Society Committee on Scientific Research in Schools indicates the progress being made by the Royal Society to foster scientific research projects by science teachers in schools. During the year covered by the report, the number of research projects increased to seventy, involving sixty-one schools. This represents an increase of seven projects and five schools over the fourth report. The Council of the Royal Society again made available a grant of £2,000 for the provision of special equipment and apparatus. During the year, the U.K. Atomic Energy Authority offered the Committee a grant of up to £1,000 per annum for the purpose of providing grants to school science teachers requiring special equipment to pursue research of interest to the Authority: the first contribution by the Authority will be made early in 1963. A gift is also acknowledged of £105 from Griffin and George, Ltd., which is to be transferred to the Science Masters' Association for the development of laboratory apparatus for schools. All the work included in the various projects was carried out with the specialist advice and assistance of Fellows of the Royal Society and of others, all of whom have generously given their help, and the Committee gratefully acknowledges the valuable help given by these advisers. Five papers have been published in learned publications by science teachers concerned with projects supported by the Committee. Appended to the report is a list of the science teachers concerned with their scientific research projects, arranged alphabetically according to schools.

British Education

THE second edition of Prof. H. C. Dent's *British Education* gives a concise but comprehensive account of the evolution of education in England and Wales, Scotland and Northern Ireland and of contemporary developments up to and including the new universities (Pp. v+70+17 plates. London: Longmans, Green and Co., Ltd. Published by the British Council, 1962. 2*s*. 6*d*.). The balance between primary, secondary and further education of all types is fairly held and all aspects are reasonably presented. With a select, but fully representative, bibliography and well-chosen illustrations it provides not only a lucid popular account but also one which the serious student may well find convenient to have at hand.

Technical Translating in Canada

THE optimistic claims that machine translation will be practicable in the foreseeable future are strongly criticized in a paper that was written by D. A. Sinclair, chief translator of the National Research Council in Canada, for the Committee on Science and Astronautics of the U.S. House of Representatives (*Man or Machine. An Assessment of the Possibilities for Closing the "Translation Gap"*. National Research Council of Canada, Ottawa, 1961). As an alternative, Mr. Sinclair proposes a comprehensive scheme for the selection, training and employment of scientific and technical translators, taking into account existing conditions in North America. Much of this would seem to be directly applicable to Great Britain, where the demand for better translations is similarly great, and it is interesting to note that French-speaking Canada has a flourishing translating profession that exemplifies many of the features recommended by Mr. Sinclair. Neither the selection nor the training of suitable candidates should provide insuperable difficulties, but employment at adequate remuneration is quite a different problem. In Canada, competent translators are said to earn less than secondary school and college teachers.

Kodak Research and Development

THIS year the Kodak Research Laboratories celebrate their jubilee. To mark the occasion, the Eastman Kodak Company has issued an attractive and informative brochure describing the scientific work carried out in these laboratories in the fields of chemistry, physics, and photographic science and technology (*Research at Kodak*—Illustrated Brochure. Pp. 20. Rochester, New York: Eastman Kodak Co., 1962). The research programme covers: (1) fundamental research, in which the objective is new knowledge; (2) exploratory research, in which basic information is utilized in the search for new materials, processes and techniques; (3) early-stage development, in which work is directed towards new materials and processes for general sale and for scientific and military applications. Members of the research staff are encouraged to write for scientific journals and more than 2,300 scientific papers have been published since the laboratories were established, including among them outstanding contributions in the field of photosensitive polymers and in the theory of the photographic process. Techniques used in the organic chemistry laboratory include nuclear magnetic resonance, electron-spin spectroscopy, ultra-violet and infra-red spectroscopy, and gas chromatography. In physics, methods of sensitometry, psychophysics, radiometry, spectrophotometry and colorimetry together with mathematical analysis have been successfully applied to the Company's problems, while fundamental research has been carried out into the effects of turbid media and atmospheric conditions on the attenuation and scattering of light. Kodak scientists are given freedom to conduct their far-ranging exploratory research for new methods of obtaining monochrome or colour images and for new applications of photography. This type of research has produced such products as simplified photomechanical printing plates, a colloidal transfer system for copying printed matter, an emulsion-coated elastic base for use in the detection of stomach, breast and intestinal cancer, and a unique photographic paper which can be processed in less than one second.

Mount Stromlo Observatory

AFTER site testing intensively in New South Wales since 1958 and more generally since 1951, it has now been announced that a final choice of site has been made for a Field Station of Mount Stromlo Observatory of the Australian National University. The Field Station is to be at Siding Spring Mountain near the town of Coonabarabran about 200 miles northwest of Sydney. The mountain has a flat top, and being one of the highest peaks (altitude, 3,820 ft. above sea-level) in the area, it has a large open horizon on all sides. Services to the region seem adequate. It is hoped to erect the new 40-in. reflector, a 26-in. reflector (now at Mt. Bingar) and a new 16-in. reflector at this site. It is hoped at a later date to move some of the telescopes now at Mount Stromlo to the Field Station and the 50-in. reflector now at Mount Stromlo may be the first to be moved, though the 74-in. reflector will not be moved. It is hoped to make the Field Station the chief observing station of Mount Stromlo while keeping the Department of Astronomy of the Australian National University, workshops and offices in their present place. Further site testing is now in progress to find the best possible observatory site in the whole of Australia. The aim here is to have a suitable site for suggestion should sufficient finance for a 120-in. reflector become available. Further details can be obtained from the Mount Stromlo Observatory, Australian National University, Mount Stromlo, Canberra.

Prestressed Concrete

IN September the Cement and Concrete Association issued a booklet by M. R. Hollington entitled *An ABC of Prestressed Concrete* (Pp. 56. London: Cement and Concrete Association, 1962). The object of this excellent and informative publication is ". . . to provide the designer and the contractor with some concise information about prestressed concrete and its constituent materials". As the title implies, the subject-matter is arranged alphabetically and the scope is revealed by these headings: anchorages, anchor stressing, bond, cap cables, codes of practice, compacting factor test, composite construction, concordant tendon profile, concrete testing, cover, creep, deflexion, ducts, elastic deformation, end-block design, fire resistance, formwork, frictional losses, grading of aggregate, grouting, high-tensile alloy steel bars, indented and crimped wire, jacks, joints, kern, load testing, losses of prestress, mix design, notation, overloading, partial prestressing, permissible stresses, portland cements, post-tensioning, precasting, prestressed concrete designs, pretensioning, proof stress, quality control, relaxation, shrinkage, spacers, standard bridge beams, steam curing, strand, transfer, transformed tension profile, ultimate strength of beams, vebe test, vibration, wire, and Young's Modulus. This *ABC* is a most useful contribution to the literature of prestressed concrete and will be found to be of great practical value to all concerned with the use of normally reinforced concrete as a structural material. While assuming that the reader possesses a basic knowledge of the theory of prestressing, the explanations under each heading are clear and concise. It is pointed out that working efficiency of any prestressed member is dependent on a number of variables the quantitative assessment of which is often necessary by the structural engineer. In this connexion numerical values given to these factors in this booklet are based on the British Standards *Code of Practice CP 115 : 1959, The Structural Use of Prestressed Concrete in Buildings*. References are made to experimental results obtained at the Research Station of the Cement and Concrete Association, and footnotes direct the reader to relevant British Standards and other works on this important subject.

The Ciba Journal

THE *Ciba Journal* for Autumn 1962 (No. 23) includes a note on demonstrations of advances in photochemistry shown in colour on the 'Eidophor' screen at Zurich last summer, Dr. K. Hofmann's remarks on molecular medicine delivered at the dedication last May of Ciba Summit's Development Research Centre, and some account of the Goregaon Centre for fundamental biological chemical research, near Bombay, to be completed next spring. The new institute will co-operate fully with university and Government research institutions in India and other parts of Asia. There is a note outlining the differences in structure and behaviour between 'Doriden' (or glutethimide) and thalidomide, and an account of the scope and activities of the Summit Scientific Information Centre, in which Dr. F. Knill stresses the need to limit mechanization to the purposes which justify its expense and effort: the human factor is still important. Among shorter articles there is a description of the Snowy Mountains hydroelectric and irrigation scheme.

Bibliography of Gas–Liquid and Liquid–Liquid Interfaces

THE Research Department of Joseph Crosfield, Ltd., have made a handsome present to the scientific world with their new bibliography of published work on gas–liquid and liquid–liquid interfaces. The compiler is Dr. D. W. Stephens, and he has done a very thorough job: there are more than 2,600 references. The topics covered include some in which solid surfaces are involved also, a large number of papers on contact angles being cited. The work since 1890 is very thoroughly dealt with, and very little seems to have been missed; some references have dates as recent as 1961. Rayleigh's classical work is noted; but perhaps wisely, since the bibliography is intended for present-day research workers, the early history is lacking; there is no mention of Thomas Young, Laplace or Dupré, and Clerk Maxwell's comprehensive article "On Capillarity", in pre-1914 editions of the *Encyclopædia Britannica*, is not mentioned. This is a pity, since it contains an admirable summary of the very early work, even back to Leonardo da Vinci. But one cannot have everything, and this bibliography is so comprehensive that it will save research workers and writers of books untold hours of searching in the literature. In an introduction, Prof. J. T. Davies directs attention to the alarming and self-defeating increase in the rate of publication of papers. One example may be quoted: more than 100 communications on the effect of surface films on the rate of evaporation of water, a subject which assumed technical importance only a few years ago, are cited. But bibliographies such as this, easy to use and concise, arranged under both authors and subjects, do help to overcome this ever-increasing plague which now besets scientific literature, in a most helpful way. The publishers' address is: Joseph Crosfield and Sons, Ltd., Bank Quay, Warrington, Lancashire.

Genesis of Volcanic Pipes by Fluidization

IN 1961 the Russian geologists, V. I. Mikheyenko and N. I. Nenashev, published a remarkable demonstration that the diamond-bearing pipes of Yakutia were intruded as a relatively cold, gas-charged mush of solid-rock fragments, and not, as hitherto supposed, predominantly in a water-enriched magmatic state. An English translation of this report has recently appeared (*International Geology Review*, 4, 916; 1962). Although these diamantiferous pipes and dykes were emplaced in late Mesozoic times, the absolute age of the kimberlites of which they are formed, established by potassium : argon ratios on the component phlogopite mica, is not less than 660 million years. In other words, the formations were not molten within 500 million years of the time of their intrusion, but were emplaced from depth as a cold, fluidized, aqueous slurry which in its ascent disrupted from the country-rocks the many types of xenolith which the pipes contain. These observations, coupled with the recent Russian discovery of diamonds in a xenolith of plagioclase-bearing eclogite-like rock of crustal type, may materially affect geological thinking on the origin of diamonds and on the deeper structure of the continental crust. Contemporaneously, emphasis has been placed on the importance of fluidization or 'gas-tuff streaming' in a series of recent papers by Dr. E. H. Francis on the Carboniferous volcanic vents in the Midland Valley of Scotland, the latest of which is on "Volcanic Neck Emplacement and Subsidence Structures at Dunbar, South-East Scotland" (*Trans. Roy. Soc. Edin.*, 65, No. 2. Pp. 41–58 + 2 plates. Edinburgh: Royal Society of Edinburgh, 1962. 8*s*. 6*d*.). Sixty years ago, Sir Archibald Geikie drew comparisons between the Scottish necks and the diamond pipes of South Africa. The former have never yielded a diamond; but it is nevertheless of interest to find genetic conclusions drawn from field observations in Scotland so closely paralleled by the results of geochronological research on the diamantiferous diatremes of Siberia.

Pinus radiata

Pinus radiata, although a tree of little importance in its native habitat of southern California, has established itself as a most important exotic, particularly in the southern hemisphere. Wherever climate and soils are suitable, it has given outstanding results. It occupies a very prominent position in New Zealand forestry, supplying about half the total cut of home-grown timber. In addition to lumber, it is the sole raw material used in the New Zealand pulp industry. Thus, besides home consumption, this exotic is also providing produce for export. The successes achieved are all the more remarkable because the *radiata* stands are only 40 years old or less. Similar results, although on a smaller scale, are being obtained in Australia and South Africa, and it is likely that much of Chile's pulp industry will be dependent on this pine. Success is also being obtained in Spain, where the increment is much higher than obtained from the indigenous conifers. The recent Food and Agriculture *Forestry and Forest Products Studies*, No. 14, by C. W. Scott, is a remarkably complete monograph on *P. radiata* (Pp. xii + 328. Rome: Food and Agriculture Organization of the United Nations; London: H.M.S.O., 1962. 17*s.* 6*d.*; 3.50 dollars). It begins with a detailed description of the tree in its habitat and then as an exotic. Sylviculture, management, pathology, utilization and marketing are all considered, and there are ten appendixes and a good bibliography. The illustrations are excellent. It is fortunate that a person of C. W. Scott's experience was found to prepare this monograph. Not only is he familiar with *P. radiata* in Chile but he is also a forester of great experience who knows what to record in a book to make it of real value. Throughout the monograph one appreciates the balanced outlook of the author in such statements as "The whole future of *P. radiata* and all other exotics depends on so handling them that they remain healthy and free from disastrous epidemics or soil deterioration".

The Society for the Study of Growth and Development

THE following have been elected officers of the Society for the Study of Growth and Development: *President*, John G. Torroy (Harvard University); *Secretary*, William A. Jensen (University of California); *Treasurer*, Dr. Marcus Singer (School of Medicine, Western Reserve University); *Editor of the symposium volume*, Dr. Michael Locke (Western Reserve University); *Member of the Executive Committee*, Dr. Clement Markert (Johns Hopkins University).

The twenty-second annual symposium of the Society will be held at the University of Connecticut during June 17–19. It will be devoted to the general topic, "Cellular Membranes in Development". Further information concerning the Society or the symposium can be obtained from Dr. William A. Jensen, Department of Botany, University of California, Berkeley 4, California.

The John Murray Travelling Studentships in Oceanology and Limnology

THE following awards have been made by the Council of the Royal Society of John Murray travelling studentships for research in oceanography and limnology: to M. V. Angel of the Department of Zoology, University of Bristol, to enable him to extend his experience and knowledge of marine plankton and apply the techniques developed for investigating *Daphnia* endocrine systems to marine plankton in R.R.S. *Discovery* during the International Indian Ocean Expedition; to P. Herring of the Department of Zoology, University of Cambridge, to enable him to investigate the control and functions of the vertical distributions of zooplankton in R.R.S. *Discovery* during the International Indian Ocean Expedition; to Dr. A. Prakash of the Fisheries Research Board of Canada to enable him to carry out work on the dynamics of plankton blooms, with particular reference to efficiency of primary production in tropical waters, and other studies within the framework of the International Indian Ocean Expedition; to G. Topping of the Department of Oceanography, University of Liverpool, to enable him to carry out general chemical work and to study the distribution and variation of trace elements in sea-water aboard R.R.S. *Discovery* during the International Indian Ocean Expedition.

Announcements

H.R.H. PRINCE PHILIP, DUKE OF EDINBURGH, has been admitted as a Royal Fellow of the Australian Academy of Science in Canberra.

DR. E. VAN TONGEREN has joined Mr. M. D. Frank in the management of the North-Holland Publishing Co., Amsterdam.

A SYMPOSIUM on "Equatorial Geophysics", sponsored by the International Union of Scientific Radio and the Interamerican Union of Geodesy and Geophysics, will be held at the Instituto Geofisico del Peru during February 4–8. Further information can be obtained from Albert A. Giesecke, Instituto Geofisico del Peru, Apartado 3747, Lima.

THE fourth omnibus conference on "The Experimental Aspects of Nuclear-Magnetic-Resonance Spectroscopy" will be held at the Mellon Institute, Pittsburgh, Pennsylvania, during February 28–March 2. Further information can be obtained from the chairman, C. W. Wilson, Research and Development Department, Union Carbide Chemicals Company, South Charleston, West Virginia.

THE third international symposium on "Quantum Electronics", sponsored by the Office of Naval Research, the Institute of Radio Engineers and the Société Française des Electroniciens et des Radioélectriciens, will be held at the Unesco Palace, Paris, during February 11–15. Further information can be obtained from the Third International Symposium on Quantum Electronics, 7 rue de Madrid, Paris 8.

A COURSE of lectures and practical work on "The Immunological Assay of Insulin", organized by the School of Clinical Research and Postgraduate Medical Teaching, University of Cambridge, will be held in the Department of Biochemistry, University of Cambridge, during December 17–18. The course is designed for research workers and hospital laboratory workers interested in the assay of insulin in body fluids, tissue extracts, etc. The fee for the course will be two guineas. Further information can be obtained from the Secretary, the Medical School, University of Cambridge.

THE first Australian conference on "Electrochemistry", sponsored jointly by the Royal Australian Chemical Institute, the University of Tasmania and the University of New South Wales, will be held in Sydney during February 13–15 and in Hobart during February 18–20. The following topics will be under discussion: (1) Sydney, solid-state chemistry, thermodynamics of electrolytes, electroanalytical methods, applications (plating, anodizing), corrosion and theory of boundary layers; (2) Hobart, electro-winning and electro-refining, electrode processes, fused salts, fuel cells and non-aqueous electrochemistry. Further information can be obtained from Dr. Felix Gutmann, Physical Chemistry Department, University of New South Wales, P.O. Box 1, Kensington, New South Wales.

THE SUB-DEPARTMENT OF ANIMAL BEHAVIOUR, UNIVERSITY OF CAMBRIDGE

IN 1950, the Cambridge University Department of Zoology established an Ornithological Field Station at Madingley, about four miles from the centre of the City. The object of this was to provide aviary and other facilities for the investigation of bird behaviour, with special reference to the relative influence of two factors affecting the development of behaviour in the individual. These two factors are, on one hand, the innate disposition of the animal—in broad general terms, its 'instincts'—and on the other its ability to profit by experience, that is to say, the degree to which it can display the various types and degrees of learning. Birds are of particular interest from this point of view in that they combine high learning ability with elaborate instinctive behaviour patterns to an extent which is probably unique in the animal kingdom. The Field Station was from the first under my general direction, with Dr. R. A. Hinde as curator. As the work developed, experiments were extended to a number of species of mammals in addition to birds and the title was changed to the Field Station for the Study of Animal Behaviour. In 1960, the University established a Sub-department of Animal Behaviour as part of the Department of Zoology, with me as director and Dr. Hinde as assistant director of research. It was envisaged that there would ultimately be 8–10 other workers. Of these, three or four would be rather senior, holding relatively long-term research grants or appointments—the total scientific strength of the Station being completed by research students and senior visiting workers from other universities. In addition, there would, of course, be an appropriate technical staff.

This development, and the experience of a number of years, made clear the necessity for a permanent building in addition to the temporary accommodation which had sufficed hitherto. The earlier stages of development of the Field Station had been made possible by generous help from various sources, particularly the Nuffield Foundation and the Josiah Macy Foundation of New York. When the more extensive needs became known, the former again came most generously to our aid and gave the University a grant of £50,000, of which £30,000 was to be allocated to the immediate capital needs and the remaining £20,000 to be devoted to the current expenditure over a period not exceeding seven years. The Rockefeller Foundation generously followed this up with a grant of £23,330 of which £5,830 is to be used for the purchase of scientific equipment and £17,500 for more general expenses of research over a five-year period.

The site consists of about 4½ acres of field and woodland, the whole fenced with vermin-proof fencing. Within this area are outdoor pens and enclosures, a monkey house for the accommodation of four groups of seven or eight monkeys, each with extensive indoor and outdoor quarters. Madingley Wood

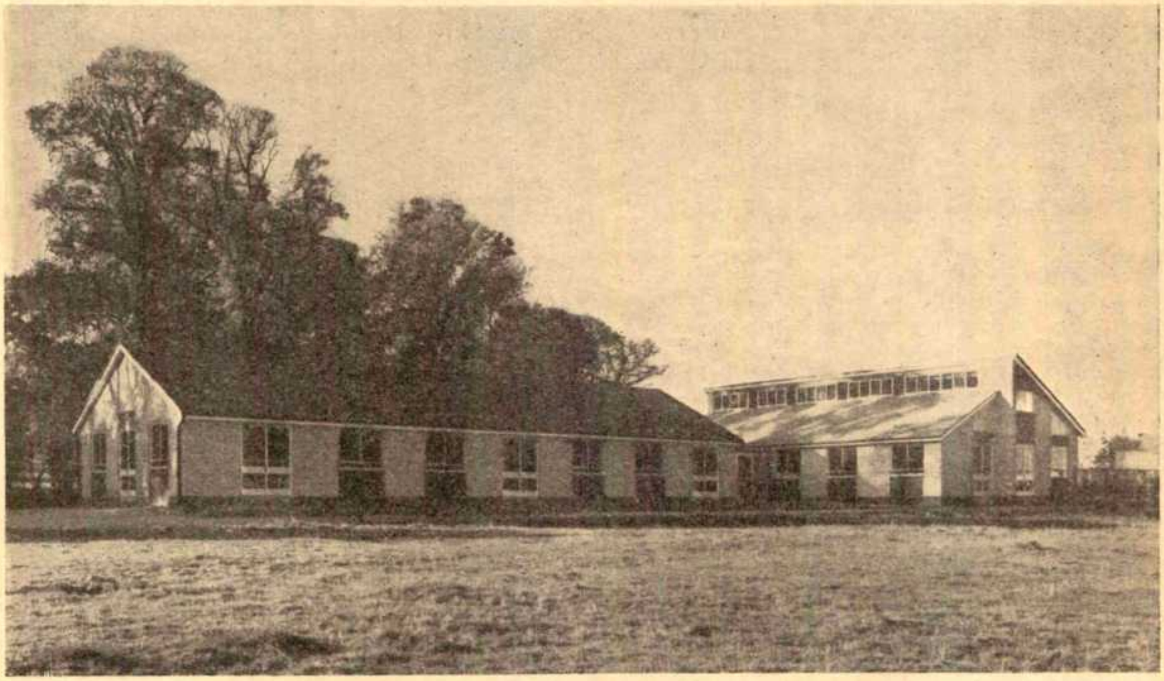

Fig. 1. The Sub-department of Animal Behaviour, University of Cambridge

(38 acres), which is a biological preserve of the University, and the lake in Madingley Park are also available for certain research projects. There are 60 small and 12 large aviaries and a large number of indoor bird-rooms and flights, as well as two sound-proof rooms especially constructed for the isolation of experimental birds from those frequencies which constitute the essential basis of bird songs and call notes. An admirable building (Fig. 1), designed by Mr. Peter Bicknell, of Messrs. Hughes and Bicknell, Cambridge, has now been erected and the Sub-department occupied it in August 1962. The new building is divided into approximately twelve individual research rooms, dark room, histology room, office, accommodation for full equipment of sound-proof cages, garage, workshop, etc. There are also three large rooms, one of which is at present being used as an isolation room for primates and birds, while the others accommodate small mammals and fish. The roofs are pitched, and the whole of the roof space is utilized. In one block the two roof slopes are split at the ridge to give a continuous clerestory, lighting small workrooms. In the other block there is a continuous loft 80 ft. × 30 ft. uninterrupted by roof timbers, which can be used for experiments requiring a long indoor runway or large choice chambers. There is also a house for the senior assistant in charge.

It is intended that the first main line of investigation of workers in the Sub-department should continue to be the instinct/learning problem, particularly as exemplified in the study of sensitive periods in learning. Such a heading includes several lines of work which the experience of the past few years has shown to be the most promising. With birds it would include studies on the ontogeny of new motor actions, and the continuance of studies on song-learning and vocal imitation and their sensory and motor control. Studies on the ontogeny of species-characteristic behaviour, particularly work such as that on the analysis of the role of experience in nest-building, will be continued. Studies on mammals will, as hitherto, centre round the mother–offspring relation, and the work with the now well-established colony of rhesus monkeys is proceeding. The second main field of investigation can broadly be described as 'motivation'. This, of course, interdigitates with the first—for example in the analysis of song patterns, endocrinology (particularly of nest-building) and studies of changes in responsiveness to a constant stimulus.

The third main aspect of the work can broadly be called physiology. Studies on the hormonal control of the cycle of reproductive behaviour, especially of nest-building in canaries, has already been mentioned, but a new development is the initiation of neurophysiological investigations. While much is known about the neurophysiological changes concerned with learning in mammals, the neurophysiological understanding of the essential mechanisms involved in what are generally known as 'instinctive actions' is, by comparison, meagre in the extreme. When we come to birds, in which these instinctive actions are far more obvious and highly developed than they are in the mammals, neurophysiological information is almost non-existent. The application of new techniques of central stimulation seem to offer great promise in this field.

In the past, workers in the Sub-department have been fortunate in being able to maintain close contact with colleagues in related fields. Thus we have had close co-operation with members of the Department of Experimental Psychology, under Prof. O. Zangwill, and especially with the workers on primates there—Dr. L. Weiskrantz and his associates. Also within the University, contact has been maintained with the Department of Physiology (Sir Bryan Matthews), and we look forward to future collaboration with the new Department of the Physiology of Reproduction under Prof. A. S. Parkes. Outside Cambridge, we have worked closely with Dr. John Bowlby of the Tavistock Clinic, who is investigating mother/infant interaction in man. We hope that such co-operation will be increased and extended as a result of the new developments because we believe that ethology has a special part to play in the establishment of mutually profitable relations between the various behavioural sciences.

W. H. THORPE

PROBLEMS OF COMMUNICATING SCIENTIFIC IDEAS

A *TENTATIVE Study of the Publication of Original Scientific Literature**, issued by the Abstracting Board of the International Council of Scientific Unions, like the study of *The Foreign Language Barrier in Science and Technology* †, recently published by Aslib, is concerned with the availability of original publications in foreign languages. Both are based on fresh surveys, but, except in respect of courses in Russian for scientists, neither adds substantially to the findings of the report, *Scientific and Technical Translating and other Aspects of the Language Problem*, issued in 1957 by the United Nations Educational, Scientific and Cultural Organization (see *Nature*, **180**, 1170; 1957). However, the Aslib report refers to this earlier and much more comprehensive report. The report from the International Council of Scientific Unions is based on a questionnaire sent early in 1960 to 260 selected periodicals, mainly in Europe, but 86 did not reply. The survey did not pretend to give a representative sampling of original publications, but in view of the fact that a sampling of 1,000 periodicals for the Unesco survey indicated that some 61·5 per cent of the papers were in English and only 17·4 per cent in French and 2·2 per cent in German, the selection of 72 French periodicals and 33 German compared with 39 British and 63 United States seems to rob the findings of some substance. Russian periodicals, which in the Unesco survey accounted for some 10 per cent, were not included, though this language was in 1957 competing for the second place, and Japanese was then challenging French for fifth.

---

* Conseil International des Unions Scientifiques, Paris. Bureau des Resumes Analytiques. *A Tentative Study of the Publication of Original Scientific Literature.* Pp. 11 + 16 tables. (Paris: Conseil International des Unions Scientifiques, 292 rue Saint-Martin, 1962.)

† *The Foreign Language Barrier in Science and Technology.* (A study based upon three investigations carried out in the Research Department by Moira Phillips.) Pp. vi + 57. (London: Aslib, 1962.) 12*s*.

This survey, however, was not primarily concerned with language: it was equally concerned with the selection of papers for publication and with financial aspects, on which later, however, the only firm conclusion drawn was that no law of political economy appears to have any validity in this field of publication. Only in Canada did some effort appear to have been made to organize scientific publication financially and there is a very wide variation in the price demanded of the scientific subscriber for 10,000 words of scientific literature. Sometimes a single periodical has widely different subscription rates for different categories of subscribers; even within one country and one scientific discipline, rates may vary widely with no apparent explanation. The mean value for commercial publishing seems to be higher everywhere than the mean value for periodicals owned by non-profit concerns or societies, though a few exceptions can be found.

Submission of papers to a referee was practised by 71 per cent of the periodicals, but was not universal, especially outside the United States; 72 per cent of the periodicals publish authors' abstracts, but only 40 per cent decline to publish a paper unaccompanied by an abstract written by its author. Only 38 per cent of the periodicals appeared to be aware of the *Guide for the Preparation of Synopses*, in spite of the efforts made since 1949 by Unesco and the Abstracting Board of the International Council of Scientific Unions to distribute this and make it known; only a minority (6 per cent) of editors have taken steps to make it known to the authors of papers, while only a very few have framed and distributed their own rules.

The Aslib report is based on three studies carried out by Miss Moira Phillips, of the Aslib Research Department, but the introduction, while rightly stressing that in the immediate future an increasing proportion of the world's scientific literature will be in Russian, Chinese and Japanese, in urging the importance of a knowledge of these languages, and of cover-to-cover translations, appears to underestimate both the outstanding importance of English itself as a medium of communication and of the economic and other considerations which will tend to encourage publication in one or other of these four major media as against nationalistic considerations. The first of the three studies sought to establish how many hours of tuition were necessary to enable a scientist to acquire sufficient knowledge of Russian grammar, construction and vocabulary to understand Russian papers at least on his own subject. The second was a study of cover-to-cover translations with the view of seeing to what extent it would be feasible to meet the demand for translations by cover-to-cover publications. In this, Dr. D. J. Urquhart comments that the number of *ad hoc* translations made before a cover-to-cover translation is no measure of the use of the cover-to-cover translation, which is a disseminating medium in its own right. The third study was of the participation and co-operation in the *Commonwealth Index of Unpublished Scientific and Technical Translations*.

Summarizing the three studies, Mr. C. W. Hanson concludes that language barriers separate English-speaking scientists and engineers from about one-third of the world's scientific and technical literature, to which learning to read foreign languages, and especially Russian, at present offers the most direct approach. A reading knowledge of Russian sufficient to enable a scientist to make sense of a paper on his own subject can be acquired with about 50–200 hours of tuition, and it would be feasible to provide sufficient courses in the United Kingdom for about one-quarter of the annual output of graduate scientists and engineers. While the demand for cover-to-cover translations of individual articles is concentrated on a few periodicals, the production of some additional cover-to-cover versions would be justified as providing ready-made translations of individual articles which may be needed. Generally, the demand for translations of individual articles is too thinly scattered over a large number of periodicals to justify a massive programme solely as a means of meeting demand. The need for translations to meet individual wants will continue, and co-operative indexes and pools provide a means of avoiding duplication of effort. The *Commonwealth Index of Unpublished Scientific and Technical Translations* operates at a profit to the community even when judged on the criterion of avoidance of duplication alone and has scope for growth. A study of the literature supports the view that the progress already made and the magnitude of the rewards of success justify major efforts in machine translation, although comprehensive machine-translation services comparable in adequacy and cost with those provided by human translators are unlikely to be achieved in less than a decade.

DANGERS OF DRINKING SEA WATER

THE salt content of body fluids is about 1 per cent. In the open ocean the salt content of the sea is about 3·5 per cent. In health, when food and water consumption is adequate, the salt concentration in the body is kept relatively constant by the kidneys; it varies, but only within a small range. In a healthy individual suffering from deprivation of water the concentration of salt in the urine does not average more than 2 per cent. This difference in salt content between the body fluids and sea water, and the physiological inability of the kidney to excrete more than a certain proportion of salt in the urine, form the basis of the generally accepted view that drinking sea water does harm. It introduces a hypertonic solution into the circulation, water is withdrawn from the tissues to restore the osmotic balance between the tissues and vascular system, the blood volume is increased, and the kidney is called on to excrete the excess fluid. The net result is progressive dehydration of the tissues, leading to disturbances in the acid-base balance, a rise in the non-protein nitrogen of the blood and the plasma protein concentration, a reduced cardiac output, thirst, and, in due course exhaustion, collapse and death.

This view was challenged by Dr. Alain Bombard who crossed the Atlantic Ocean in 1952 on an inflatable raft, taking more than two months for the voyage and relying chiefly on sea water and fluids expressed from fish to quench his thirst. The opinion he reached after these trials on himself was that people should begin drinking sea water as soon as possible before dehydration starts but in small quantities only to avoid nausea and diarrhœa. Whatever fresh water is available should be carefully husbanded, and, if there is none, fluids should be expressed from fish by squeezing them in plastic bags or towels.

Bombard's experiments were followed by Dr. G. Aury, principal medical officer of the French Navy, who, in 1953 and 1954, carried out experiments on volunteers subjected to shipwreck conditions, he himself taking part. Aury described the experiments as being successful; the sea water was readily drunk by the volunteers, they suffered from no serious complaints, and, when the experiments were over, they were able to resume their duties immediately. The experiments lasted only 2–4 days.

A German physician, Dr. Lindemann, made no less than three voyages across the Atlantic ocean, in a canoe and then in a collapsible boat. He reached diametrically opposite conclusions to those of Bombard and Aury. Sea water, he held, should never be drunk; fluids could only be expressed from fish by means of a press; and no fish should be eaten if no fresh water is available.

In 1959 the question of drinking sea water came before the Maritime Safety Committee of the Inter-Governmental Maritime Consultative Organization. The experiments of Bombard and Aury, and the wide publicity they had received, created much confusion about the drinking of sea water, and the impression had spread that the dangers of drinking sea water had been grossly exaggerated. The Maritime Safety Committee felt that an authoritative opinion was required on what had become a controversial question and asked the World Health Organization for its views. Pending a firm opinion to the contrary, however, the Committee urged that no Governments should advocate the drinking of sea water by shipwrecked mariners.

The World Health Organization convened a meeting of five internationally recognized experts, Surgeon Captain F. W. Baskerville (United Kingdom), Dr. J. Fabre (Switzerland), Dr. H. Laborit (France), Prof. R. A. McCance (United Kingdom) and Prof. A. V. Wolf (United States). They considered the effects of drinking sea water under three headings: effects on the bowel, on the body as a whole and on the mind*. Because of the well-known cathartic effects of salts, drinking sea water is likely to lead to intestinal discomfort, if not to frank diarrhœa. This effect varies in different individuals and is more likely to follow if large amounts are ingested. On the body as a whole, the effect of sea water is to overload the circulation with salt, which can only be excreted by drawing on the body water and so dehydrating the body even more. If the salts are not excreted the effect will be equally harmful because of the increase in the concentration of salts in the body fluids. Finally, the evidence shows that even small amounts of sea water affect some individuals unfavourably, while large amounts have been shown to lead to mental disturbances and even suicidal impulses.

The experts examined the contention that a limited supply of fresh water could be made to last longer if it were mixed with sea water. This has been shown to be feasible experimentally in certain animals and is theoretically possible in man. But—the group emphasized—no acceptable evidence has ever been adduced that in man sea water can be used satisfactorily to eke out supplies of fresh water. This as yet unproved hypothesis cannot, therefore, be made the basis of a practical recommendation for saving the lives of people shipwrecked at sea.

One of the reasons for advocating the drinking of sea water is to preserve morale, which, in the circumstances of shipwreck, is likely to be low. The experts held the view that morale can be maintained if it is made clear to the castaways that death from lack of water alone is scarcely possible for several days. It has been shown from experimental work that a man can remain reasonably fit without water for six days, and men have survived without it for twice that period at sea. It has also been shown that 500 ml. (one pint) of fresh water daily, if possible supplemented by 100 g (3½ oz.) of carbohydrate, will maintain a man almost without deterioration for at least six days.

The group ended its report with advice to those who have to abandon ship, including the warnings to "*Never drink sea water*. Never mix sea water with fresh water if fresh water is in short supply. Sea water has been used to moisten the mouth, but the temptation to swallow it may be irresistible and it is better not to use it for this purpose. Never drink urine".

* *WHO Chronicle*, 16, No. 9 (September 1962).

ECONOMIC LIFE OF CHEMICAL PROCESS PLANTS

"ECONOMIC Life of Process Plant" was the subject of a symposium held under the auspices of the Institution of Chemical Engineers in London on October 30. Obsolescence of chemical process equipment is a vital factor which has to be taken into account by the engineer responsible for designing chemical plants to operate at minimum cost over a reasonably predictable time, having regard to certain constraints governed by operating conditions. The author of a paper on this subject, C. S. H. Munro, concludes ". . . that the physical durability is by no means the only determining factor in the life of chemical plant equipment and that the designer must consider very carefully the future capacity requirements and the likelihood of process change". All requirements for capacity increase of plant appear to arise after periods of more than five years ". . . which is perhaps as long as any commercial estimates might be considered valid". The argument would seem to indicate a case for increasing depreciation-rates to accord with actual chemical plant life, which, as is well known in the industry, is one of the most difficult to assess compared with many other engineering projects.

A method of determining economic optimum timing for replacing chemical plant was discussed by H. R. Fisher in his apparently new solution to this problem formulated in Terborgh's *Dynamic Equipment Policy* (McGraw-Hill Book Co., New York, 1949). H. C. D. Phillips, D A. Peters and J. A.

Hodson, of the Esso Petroleum Co., Ltd., Fawley, in a paper "... written against a background of experience in the design of refinery process plant", discussed the difficult matter of "Design Philosophy in the Economic Selection of Materials for Process Plants", including questions of selection of suitable materials of construction, also methods of calculation for carrying out economic evaluations. "The Economic Life of Chemical Plant in the Nuclear Fuel Industry" was considered by G. K. Dickson, K. J. Norman and R. R. Gunton of the U.K. Atomic Energy Authority. In the nuclear industry, established in Great Britain barely fifteen years ago, evolution has had the effect of transforming what was initially a national defence project to one based on normal commercial practice. They stated that "such a rapidly and drastically changing situation has required constant re-appraisal of the economic life of the plants involved".

"Process Plant in the Gas Industry" was the title of a paper given by C. Stott (S.E. Gas Board), emphasizing some of the problems of plant design for meeting 'base' and 'seasonal load' demands (under statutory obligation), and latterly the widespread adoption of oil gasification plant to meet such conditions and to replace outdated plant. The final paper, "The Economic Life and Size of Process Plant in Underdeveloped Countries", by A. P. Shahbenderian, demonstrated how "... it is possible to assess the economically optimum life and, in particular cases, the optimum capacity of chemical plant for situations where the market is static or the rate of growth predictable". H. B. MILNER

THE TEASEL

IT is one of the minor mysteries of modern crop husbandry that teasel growing should have survived in a restricted area of south Somerset when it has died out in all the former teasel-growing areas of Britain. About four hundred acres are now grown. Formerly, teasels appear to have been widely grown. Arthur Young reported teasel beds in Essex, where they were cultivated in rotation with medicinal plants like coriander, and there were acreages in Wiltshire and Gloucestershire. When it was that the hook-ended bract of the teasel flower head was first used to comb up the pile on cloth is not known, but the process almost certainly originated in the West Country to give the characteristic hard-wearing nap to West-Country broadcloth. It is probable, too, that the husbandry of teasel-growing was either begun, or at least received its first impetus to expansion and improvement, from the influx and settlement of the Huguenot weavers.

The broadcloth industry in the hinterland towns which teasel-growers served is now largely dead, but an isolated area around the Somerset villages of North Curry, Curry Rivel and Fivehead remains devoted to teasel husbandry. This has been examined by John L. Jones, who describes how acreage fluctuates from two to three hundred and the number of farmers participating is about fifty (*Land*, 11; Autumn, 1961). For most of them it is a crop which has been grown on the family farm for generations.

Why, then, has it survived? Where a highly specialized crop survives, climate and soil must obviously be right, and the heavy loams and moderate rainfall of south Somerset suit the teasel. Another unique aspect of the soil is that much of the land is 'teart'—in the region of the country distinguished by an excess of molybdenum, which expresses itself as a copper deficiency in cattle. This in itself may be a specific ecological factor of the teasel. More possibly, it was the economic aspect of teart land farming which may have contributed to the survival of teasel-growing. For until it was appreciated that the serious cattle sickness associated with teart land could be rectified with modern treatment, the farmers concerned would have been more interested to retain any lucrative cash crop for which their land was suited than those with sound and healthy land would have been to grow teasels. Added to this is the continuity of husbandry and the skill and specialized knowledge acquired in centuries of growing.

The superiority of the teasel—the fuller's teasel, as it was formerly called—lies in the supple hookends of the bracts or awns of the cylindrical flower-heads. To-day all the Somerset teasels are bought for the northern cloth-finishing mills, where they are used to produce the brushed effect on the best-quality face cloths. For these the action of the finest wire brushes is too severe.

The teasel crop begins as a fine seed sown in drills in the spring. The early husbandry is as for roots, and the crop is hand-hoed to keep down weeds and afterwards singled out to 4 in. apart. By the end of autumn the plants are ready for transplanting—the teasel is a biennial—and lifted with a special tool called a 'spitter', which severs the long tap root. They are dibbled on to the ploughed furrow at a rate of twelve thousand plants to the acre. The convention is 30 in. between the rows and 24 in. between the plants. During this second year the plants throw out big central stems and side branches surmounted by prickly heads, which are ripe for the teaselling knife in August.

The teasel is one of the latest crops to receive the benefits of modern crop protection, which has considerably increased the yields from the fields of the more progressive growers. Squat malformed plants producing soft teasels with numerous 'dead head' plants as well had long been a mysterious problem in the Somerset teasel beds. Long field rests did nothing to help. Then the eel worm was isolated as a major teasel pest, which explained why resting between crops for long periods had not helped. The pest was being perpetuated in the soil by other crops such as oats, mangolds and beans, and on numbers of hedgerow hosts such as cleavers and chickweed. It was also being transmitted by infested seed, and teasel seed can now be pre-treated like clover to kill the pest. The growing crop may also need dusting against the teasel leaf miner—small egg-laying black-flies which hatch maggots on the leaves and cause bacterial rots. Not so easily handled, but rarely occurring, are attacks by the cucumber mosaic virus which causes leaf mottling and stunted growths, and the fungus of violet root rot, which destroys the tap root and starves the plant of nutriment.

MAGNETIC RESONANCE

It has become customary to hold a workshop in magnetic resonance each year at Varian Associates in Palo Alto, California. At these workshops new workers are introduced to the principles and practice of nuclear magnetic resonance and electron paramagnetic resonance, while those already experienced in the fields have the opportunity to discuss new developments. This custom has been adopted by the Swiss daughter company, Varian *A.G.*, the second annual workshop of which was recently held at its Research Laboratory in Zurich during September 24–28.

Lectures and laboratory demonstrations in both subjects were offered, the lectures being given in the main building of the University of Zurich while practical work was conducted at Varian's Research Laboratory. The introductory lecture to the first part of the programme—devoted to high-resolution nuclear magnetic resonance—was given by Dr. E. Rogers of Varian Associates, who was one of the Bloch group during the early days of nuclear resonance. Dr. J. N. Shoolery, also of Varian Associates, talked about the theory of nuclear magnetic resonance spectroscopy during the following two lectures, thus providing a foundation for the interpretation by the participants themselves of high-resolution spectra. Further instruction in spectra interpretation and in spectrometer operation was given by Dr. P. von Philipsborn of the University of Zurich, Dr. R. J. Abraham of the University of Liverpool, and Dr. A. Melera of Varian *A.G.* The instrumentation of nuclear resonance spectrometers was discussed by Mr. R. Wenk of Varian *A.G.*, and the course was finished by Dr. Abraham with a lecture about recent applications of proton coupling constants in organic chemistry.

The introductory lecture to electron paramagnetic resonance was given by Dr. A. Horsfield of Varian *A.G.*, and this was followed by a lecture on free radicals in solution by Dr. A. Carrington of the University of Cambridge. Dr. J. Combrisson from the French Atomic Energy Authority at Saclay talked about the applications of double resonance and the Overhausser effect in chemistry. The principles of electron paramagnetic resonance instrumentation were given by Mr. R. Tschudin of Varian *A.G.* An account of oriented free radicals in crystals was given by Dr. A. Horsfield, and Dr. A. Carrington gave a second lecture on transition metal ions and the triplet state as studied by electron resonance. Prof. R. Adams of the University of Kansas, in closing the course, spoke of the use of electron paramagnetic resonance techniques in electrochemistry. Practical work included instruction in the analyses of electron paramagnetic resonance spectra and demonstrations with an electron resonance spectrometer were given.

A total of ninety participants attended the workshop, representing most of the countries in Europe. A ladies' programme was arranged for the wives of the conference members and a workshop dinner was held at one of the old guild-houses of Zurich. It is planned to hold another workshop in magnetic resonance in Zurich in September 1963.

OCTACALCIUM PHOSPHATE AND HYDROXYAPATITE

Crystal Structure of Octacalcium Phosphate

OCTACALCIUM phosphate (OCP), also called tetracalcium hydrogentriphosphate, $Ca_4H(PO_4)_3 \cdot 2{\cdot}5H_2O$, is frequently encountered in systems containing calcium phosphates more basic than dicalcium phosphate[1–4], and it appears to have a significant role in the chemistry of bones, teeth, phosphate fertilizers, and other precipitated calcium phosphates (see following communication). Its existence as a distinct crystalline phase rather than a hydrous 'defective apatite' has been questioned[5,6], but was established by single crystal[7] and powder-diffraction X-ray studies[8]. Its X-ray, optical, and chemical properties indicate[7] that OCP is structurally related to hydroxyapatite (HA), although the two salts are not isostructural, and that OCP is composed of apatitic layers that are parallel to the *b–c* plane and separated by hydrated layers. The structure of OCP, a preliminary account of which is given here, is in accordance with these indications. The method of preparation of OCP is described in the following communication.

The following unit-cell constants of OCP were used in the structure analysis:

a = 19·87 Å α = 89° 17′
b = 9·63 Å β = 92° 13′
c = $6{\cdot}87_5$ Å γ = 108° 57′
$Z = 2(Ca_8H_2(PO_4)_6 \cdot 5H_2O)$ Space group, $P1$ or $P\bar{1}$

The centrosymmetric space group, $P\bar{1}$, which was assumed in the analysis, was verified by the success of the structure determination. Chemical analyses do not yield constant numbers of waters of hydration, and this uncertainty reflects the ease with which water enters and leaves the OCP lattice. The cell contents listed in the tabulation were used in the final structure refinement which required 172 positional and thermal parameters for the 8 calcium, 6 phosphorus, and 29 oxygen atoms in the asymmetric unit. Eleven scale factors were included also, but the parameters of the 12 unique hydrogens were omitted, so that a total of 183 parameters was used. Altogether, 2,332 independent structure factors were utilized in the refinement; of these, 1,419 were from intensities measured photometrically and 913 from intensities estimated visually. Most of the visually estimated intensities were those of reflexions too weak to be measured photometrically.

The initial structure approximation was derived from Patterson sections, $P(U,V,W)$, at levels $W = 0$, 1/4, and 1/2. Positions in two dimensions for the eight calciums and five of the phosphates were derived mostly from a series of ($hk0$) Fourier projections. The remainder of the structure was determined by a series of three-dimensional Fourier syntheses and least-squares refinements which brought the disagreement between the observed and calculated structure factors within 12 per cent. The averages for the estimated standard deviations in the positional parameters are 0·005 Å for the calciums, 0·006 Å for the phosphorus atoms, 0·021 Å for the phosphate oxygens, and 0·045 Å for the water oxygens.

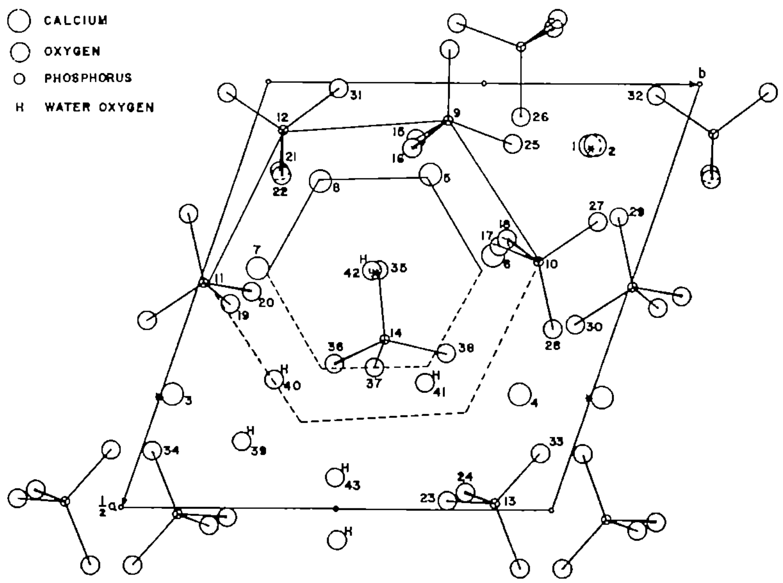

Fig. 1

The atomic parameters of OCP are listed in Table 1 and the structure, projected down the c axis, is shown in Fig. 1. The numbering of atoms in the figure corresponds with that in Table 1. The corners of the larger hexagon in Fig. 1 are the phosphorus sites as they occur in HA[*], and the corners of the smaller hexagon are the calcium sites. Only four of the sites on each of these hexagons are filled in OCP. The sites of the missing atoms are shown connected by broken lines. Four phosphorus positions of OCP closely match those of HA; but this is less true for the four calciums, particularly Ca(6) and Ca(7). A water molecule, O(41), appears to have replaced a missing calcium. The remaining four calciums of HA comprise two pairs of 'column' calciums. In OCP, one of these pairs, Ca(1) and Ca(2), is in virtually the same position as in HA, in which the two calciums lie one above the other in the position marked by the asterisk. The other pair of column calciums is split in OCP—one, Ca(3), is quite near its HA site as shown by the asterisk, and the other, Ca(4), is shifted by about 1·5 Å parallel to the b axis. The structure of OCP is a close copy of that of HA for small values of x. In the region where x approaches the value 1/4, the dissimilarities become quite apparent, and at larger values of x there is no similarity between the two salts. The region defined approximately by $1/4 > x > -1/4$ is referred to as the 'apatite layer'.

Table 1. ATOMIC POSITIONS OF OCTACALCIUM PHOSPHATE

Atom number	Parameter x	y	z

O(43)	0·4618	0·4718	0·6508

Of the remaining two phosphate ions, the one near the lower edge of the figure, P(13), ties the apatite layers together, and the other, P(14), lies in the region which in HA is occupied by the two 'hexagonal' calcium atoms which are missing in OCP. One of the oxygen atoms, O(35), of P(14) lies in the centre of the hexagon and occupies an OH^- site of HA. The other OH^- site of HA is occupied in OCP by a water molecule, O(42). Where the symbols for the phosphate oxygen, O(35), and the water molecule, O(42), overlap in Fig. 1, the asterisk depicts both the centre of the two hexagons and the OH^- sites of HA. The region bounded by the non-apatitic phosphates P(13) and P(14) is an irregular channel filled with waters of hydration. The portion of the cell defined approximately by $3/4 > x > 1/4$ is referred to as the 'water layer'.

The water molecule, O(43), shown as the pair nearest the symmetry centres at $x = y = 1/2$, appeared in the Fourier section with about one-half the electron density of the other oxygen atoms, and its temperature factor became abnormally large in the least-squares refinement. This is taken to indicate that this site was incompletely occupied in the crystal on which the X-ray intensity measurements were made.

Its layer-type structure and the similarity of part of its structure to that of HA are reflected in the chemical and physical properties of OCP (following communication). The close correspondence between the atomic positions in the apatite layer of OCP and those of HA indicates that epitaxial overgrowths of one compound on the other are very likely. The water layer, which occupies almost half the OCP unit cell, rules out consideration of OCP as a 'defect apatite' and makes formation of true solid solutions of the two compounds highly unlikely. Formation of lamellar mixed crystals of the two compounds, as described in the following communication, is more probable.

The channel in the water layer explains both the ease with which OCP loses water and the difficulty of establishing a definite degree of hydration. The formula for OCP used here is based on the assumption that the partially filled water site for O(43) is completely filled in the ideal compound. There is sufficient room at the site for a water molecule, where it is co-ordinated to eight oxygens by distances less than 3·5 Å. Complete loss of water from this site would yield the formula $Ca_4H(PO_4)_3.2H_2O$, which is sometimes given[3,4] for OCP. There is no space in the unit cell large enough to accommodate another water molecule, and it appears that earlier indications[7,8] of more than 2·5 moles of water are in error. Hayek *et al.*[3] found that two samples of OCP dried for a short time at 100° C contained 2·5 moles of water, indicating that drying at this temperature removes non-essential water without much loss of water from the lattice. In view of these results, the formula $Ca_8H_2(PO_4)_6.5H_2O$ would be a better designation for OCP because it avoids fractional moles of hydration, it represents the asymmetric unit, and it is consistent with the common name.

The asymmetric unit of OCP contains two non-water protons which may form interphosphate hydrogen bonds. One such hydrogen bond is indicated by a distance of 2·47 Å between oxygens O(20) and O(36). This hydrogen presumably contributes to the weak 2,400 cm^{-1} infra-red absorption reported for OCP (ref. 10) and for 'calcium-deficient' apatites[11]. The other interphosphate oxygen-to-oxygen distances are greater than 2·9 Å, and a second interphosphate hydrogen bond cannot be located definitely on the basis of the present information.

The great variety in the anion–cation combinations which form apatite-type structures indicates that a high degree of stability is associated with this atomic arrangement. OCP appears to be the first-established compound with this arrangement in a layer-type structure, and it is noteworthy that this structural feature persists even though it is present in only about one-half of the unit cell. Arnold[1] and Carlstrom[5] suggested that OCP is a hydrated, layer-type modification of HA. Their views that the layers are formed simply by replacement of calcium ions by hydronium ions and that the layers are normal to the *c* axis were not borne out by the structure determination.

The two most common habits of HA (following communication) are such that the forms (100) could be the major contributors to the surface area of the crystals. Since the layers of OCP also are parallel to the 100 face, the structure of the water layer may prove to be a useful model for describing the interface between the apatite crystal and the aqueous phase.

The two-dimensional phase of this work was done at the University of Amsterdam on a grant from the Rockefeller Foundation, Agriculture, with advice of Prof. Caroline H. MacGillavry of the Laboratory for Inorganic Chemistry. Mr. Abraham Kreuger of the Netherlands Organization for Pure Scientific Research (Z.W.O.) prepared the films from which the intensity data were collected.

Crystallographic and Chemical Relations between Octacalcium Phosphate and Hydroxyapatite

MANY investigators[1,5,6,12–14] have observed that precipitated calcium phosphates that give apatitic X-ray patterns often have mole ratios Ca : P less than that of hydroxyapatite (HA), $Ca_5(PO_4)_3OH$. Most of these investigators have advanced explanations for this apparent anomaly, none of which is entirely satisfactory. On the basis of a recent determination (preceding communication) of the structure of octacalcium phosphate (OCP), $Ca_4H(PO_4)_3.2{\cdot}5H_2O$, we offer another explanation which is consistent with the crystal structures of these two calcium phosphates. We have suggested[7] that HA and OCP form crystalline interlayered or lamellar mixtures analogous in this respect to clays. Such intra-crystalline mixtures not only account for apatitic precipitates with ratios Ca : P less than that in HA, but also explain observed chemical and physical properties of precipitated basic calcium phosphates.

We have obtained further evidence in support of this explanation from X-ray and petrographic investigations of basic calcium phosphates the mole ratios of Ca : P of which ranged from 1·33, that in OCP, to 1·67, that in HA, and of products obtained from OCP by dehydration in air, hydrolysis in boiling water, and treatment with fluoride solutions. Many of the alteration processes were observed with single-crystal X-ray techniques. The basic calcium phosphates were prepared in several ways, including titrations of phosphate solutions with solutions of calcium salts, ammoniation of acidic calcium phosphate solutions, hydrolysis of dicalcium phosphate, and diffusion of solutions of calcium acetate and sodium phosphate. The temperatures of the preparations ranged from 20° to 100° C.

The crystals used in the single-crystal X-ray studies were prepared by diffusion at 50°–60° C of 0·5 M sodium phosphate solution into a 0·5 M calcium chloride solution. Both solutions were also 0·5 M in sodium acetate, as was the barrier solution; all were adjusted to *p*H 8. The optical properties of some of the crystals showed that they had partially hydrolysed.

The optical properties of OCP were measured on crystals that were prepared by slow hydrolysis at 40° C of dicalcium phosphate in 0·5 M sodium acetate solution[7].

OCP crystallizes as thin (100) blades of triclinic : pinacoidal symmetry. The blades are elongated along *c* and modified by the set {010} and the terminating set {011}. Contact twinning with (100) as the twin plane was commonly observed optically. Single-crystal X-ray patterns commonly revealed twinning with *c* as the twin axis, and this is probably the polysynthetic twinning observed optically. In both modes of twinning the (100) is the composition plane.

The crystals are biaxial (–) with a $2V$ of 50°–55° (calc. 54°). The refractive indexes measured by the immersion method at 25° C are $N_\alpha = 1{\cdot}576$, $N_\beta = 1{\cdot}583$, and $N_\gamma = 1{\cdot}585$. The optic plane is inclined to the (100), where its trace on that face is at 78° relative to *c* in acute α. The acute bisectrix lies in the quadrant defined by *a*, *-b*, *-c*. One optic axis is roughly normal to (100), which accounts for the very low birefringence of crystals in their preferred orientation. Dispersion $(r > v)$ is very weak. The specific gravity obtained by the sink–float method is

2·61 g/cm^3, and the value calculated from refractive indexes[17] is 2·59 g/cm^3.

The indexes of refraction of microscopically coarse, euhedral crystals of synthetic HA with the correct chemical composition are $n_\epsilon = 1{\cdot}640$ and $n_\omega = 1{\cdot}646$.

Preparations with ratios Ca : P between those of HA and OCP give X-ray powder-diffraction patterns with lines of both salts, and the relative intensities of the OCP lines generally decrease and those of the HA lines increase as the ratio Ca : P increases. Individual preparations may appear homogeneous under the microscope because of the uniform appearance of the crystals. Optically, however, the individual crystals display wavy extinction, symmetrical extinction without the expected conoscopic figures, or marked variation in refractive indexes from one crystal to another. In some preparations, the variation in refractive indexes is slight; but in others it extends over much of the range between OCP and HA. The optical properties of individual crystals show them to be intra-crystalline mixtures, even when they appear superficially homogeneous.

The idea that crystals of this type are lamellar mixtures of HA and OCP (ref. 7) was supported by the features of close structural similarity in the two salts (preceding communication). Proof of this idea was supplied by a single-crystal X-ray study of an optically homogeneous 'crystal' the indexes of refraction of which were between those of HA and OCP. Its zero-layer Weissenberg pattern from a c-axis setting could be indexed on the basis that it contained both salts with the b and c axes of the HA collinear, respectively, with those of the OCP.

The mean index of refraction of a lamellar mixed crystal should increase roughly in proportion to the HA content, and Posner and Perloff[18] found a nearly linear relationship between the mean index and the ratio Ca : P in their preparations. An exact relationship of this type is unlikely, however, because both non-essential water[19] and the history of the sample have considerable effects on the refractive index. The optical indicatrix does not change in a simple manner with the ratio Ca : P because the mixed crystals are very thin, the OCP component has a pronounced tendency to twin, and the conoscopic figures are rarely visible and are indistinct and composite when they can be seen. Lamellar intra-crystalline mixtures should produce indistinct conoscopic figures when viewed normal to the plate because the direction then is nearly parallel to an optic axis of the OCP component and perpendicular to the optic axis of the HA. On edge view, OCP is optically length slow and HA is length fast. In a lamellar mixture these effects should tend to compensate each other, and the birefringence should be minimum in a crystal containing about two parts of HA and one part of OCP. This mixture would have a mean refractive index of about 1·625, and crystals with indexes near this value show feeble birefringence on edge view.

The lamellar crystals are so thin that the different layers cannot be distinguished under the microscope, so it is not known how many layers are in any given crystal or whether the usual number of layers is large or small. There are two processes by which the lamellar mixed crystals might be formed: one of these, epitaxial overgrowth, might produce crystals with many layers; and the other, hydrolysis, might produce crystals with few layers.

Because of similarities between the structures of HA and OCP (preceding communication), epitaxial overgrowths of one compound on the other should occur easily. Variations in the composition of the liquid phase in the immediate vicinity of a growing crystal, as in a dropwise neutralization, could cause alternate deposition of first one compound and then the other. This type of lamellar growth could result in crystals with many layers.

Hot aqueous solutions cause OCP crystals to hydrolyse to pseudomorphs the properties of which progressively approach those of HA. Crystals produced in this manner may contain few layers, such as a layer of OCP sandwiched between two layers of HA.

It would be difficult to demonstrate that the lamellar mixed crystals can be formed by epitaxial overgrowth alone. OCP hydrolyses so readily to HA, particularly at temperatures above 50° C, that this alteration could be occurring even under conditions where the epitaxial overgrowth mechanism appears predominant.

Hydrolysis of Octacalcium Phosphate. In boiling water the progressive hydrolysis of OCP to HA is reflected in a gradual increase in indexes of refraction. At the same time, the intensities of the OCP lines in the X-ray powder pattern of the residual solids decrease, and after continued boiling the solids give sharp patterns of HA. The Weissenberg pattern of an OCP crystal which had been boiled in water for 6 h showed reflexions from both OCP and HA, with the b and c axes, respectively, of OCP collinear with those of HA. The pattern of an OCP crystal that had been in boiling water for 72 h, however, was essentially that of HA alone. The reflexions were sharp, and the pattern showed the full hexagonal symmetry of HA, which indicated that there had been considerable re-organization of the lattice during the hydrolysis.

Even after prolonged boiling, the index of refraction of the residue was never higher than 1·635. It then appears either that the hydrolysis is never completed or, more probably, that the resulting pseudomorphs contain fissures that result from incomplete closure of the lattice after loss of water and phosphate ions, and possibly calcium ions. The fissures, which probably are parallel to the (100) face of the original OCP, could be sites of entry and retention of carbonate and other foreign ions in sedimentary phosphorites, hard tissues, and other apatitic materials that may be formed from OCP, and they could also contribute to internal or 'entrapped' surface area[20]. Pseudomorphs formed by hydrolysis of OCP in the presence of carbonate ions give strong tests for carbonate.

Anhydrous dicalcium phosphate (DCPA), $CaHPO_4$, is sometimes formed as a separate phase in the hydrolysis of OCP, in agreement with phase-rule considerations of the system $CaO–P_2O_5–H_2O$ (ref. 21).

Magnesium, even in concentrations as low as 0·001 N, markedly inhibits the hydrolysis of OCP. This inhibition may result from the formation of a magnesium complex on the terminal edges of the crystals that impedes loss of water molecules and ions from channels in the 'water layers' (preceding communication) of the OCP, and may be important in the growth and development of hard tissues.

OCP probably was not the most stable calcium phosphate under any of the conditions of its preparation, even though OCP precipitated in preference to HA and DCPA. The rapid precipitation and subsequent alterations of OCP go far to explain some complications in the chemistry of basic calcium phosphates. As an example, when 3 g of dicalcium phosphate dihydrate, $CaHPO_4.2H_2O$, was added to 100 ml. of distilled water at 85° C with continuous stirring, OCP crystals were observed as a separate phase within 5 min. These crystals grew for about 15 min until the dicalcium phosphate dihydrate nearly disappeared. At about this time, aggregates of extremely fine acicular crystallites of HA appeared, and soon rounding of edges of the OCP crystals indicated that the continued precipitation of HA was maintained by dissolution of OCP. The remaining OCP was converted to apatite, mostly through hydrolysis *in situ*, when the mixture was allowed to cool and stand overnight. Thus, HA apparently was produced by two mechanisms, and its acicular or platey habit showed whether it had been produced by direct precipitation or hydrolysis, respectively. At lower temperatures, conversion of dicalcium phosphate dihydrate to DCPA, rather than formation of HA, appeared to terminate the precipitation of OCP.

Precipitates with low indexes of refraction and with ratios Ca : P near those of OCP usually are relatively large thin blades similar in morphology to OCP. As the compositions and indexes approach those of HA, the typical habit becomes rosette clusters of very small scalar crystals. Precipitates in which the ratio Ca : P was essentially that of HA consisted of stellate clusters of delicate needles and only then did the crystallites have the hexagonal habit of HA.

Apatitic crystallites in bone are present with both scalar and needle habits[22]. The co-existence of crystals of two habits is consistent with the two mechanisms of formation of HA—scalar crystals from partial or complete hydrolysis of OCP (ref. 7), and needle crystals by direct precipitation of HA. There is a possibility, however, that a few layers of OCP in the seeds from which the scalar crystallites developed may have modified the directly precipitating HA into a platey habit. These crystallites, however, are (100) plates and not distortions of the (001) platey habit of HA as has been implied[1].

Reaction of Octacalcium Phosphate with Fluoride. In aqueous systems containing low concentrations of fluoride ion, fluorapatite is the most stable calcium phosphate[23], and OCP is reported to react with fluoride to produce an apatite[24]. It is significant that this reaction also occurs *in situ*, and the resulting crystals are pseudomorphs after the original OCP. In an examination of this reaction, a single crystal of OCP was mounted on an X-ray goniometer and its zero-layer Weissenberg pattern from a *c*-axis setting was obtained after the crystal had been immersed in 0·1 N sodium fluoride solution at 45° C for different times. Only OCP reflexions were present in the pattern of the untreated crystal; both apatite and OCP reflexions were present in the pattern after 5 h of immersion, and, except for a few very faint OCP reflexions, only apatite reflexions were present in the pattern after 9 h of immersion. The apatite reflexions were less sharp than the OCP reflexions, indicating that the apatite 'crystal' was composed of oriented sub-units. The orientation of the apatite crystallites relative to the original OCP was the same as for the OCP–HA crystals described previously.

The multicrystalline character of the apatite crystal was indicated further by the fact that it fell apart while being handled for optical study. In contrast to dehydrated or hydrolysed OCP crystals, fluoride-treated OCP crystals are very soft and smear easily, and their multicrystalline character implies that they may adsorb or occlude relatively large amounts of impurities. If OCP is present in tooth enamel, fluoride treatment would increase its chemical stability but may decrease its mechanical strength.

When a 1-g sample of OCP was treated with 100 ml. of 0·1 N sodium fluoride solution at 45° C for 7 days, the residue dried at 105° C for 1 h weighed 0·844 g and contained CaO 52·9, P_2O_5 41·2 and fluorine 4·0 per cent. This composition and the loss in weight indicate that the product was an impure fluorapatite (theoretical for $Ca_5(PO_4)_3F$, CaO 55·6, P_2O_5 42·2, fluorine 3·8 per cent). It is probable that the impurities can be attributed to the multicrystalline character noted here. With the same treatment, fine-grained HA took up only 0·4 per cent fluorine, indicating that HA reacts much slower with fluoride than OCP. Similar treatment of materials with compositions between those of HA and OCP caused fluorine uptakes roughly proportional to the OCP contents calculated from the ratios Ca : P. It is concluded that, when a lamellar mixed crystal of HA and OCP is treated with fluoride solution, the resulting crystal is largely fluorapatite interlayered with HA.

Dehydration of octacalcium phosphate. On drying at temperatures slightly above 100° C, OCP loses some of its water of crystallization without apparent change in its X-ray powder diffraction pattern (preceding communication and ref. 3), although the mean refractive index increases slightly. As the drying temperature is raised, the material progressively loses water, the 18·7-Å line of OCP shifts to slightly lower spacings, the OCP lines in the X-ray pattern gradually weaken and disappear at about 180° C, and the refractive index rises to a maximum of 1·61, which is well below that of HA. Except for the 002 line, the powder pattern of material dried at 180° C is very diffuse; it resembles that of a poorly crystallized apatite, and it contains no DCPA lines. The presence of DCPA in a sample heated at 220° C, however, has been detected[7] by X-ray diffraction.

The Weissenberg patterns of a single crystal of OCP which had been dried at 180° C contained diffuse spots which corresponded in position and intensity to those of an apatite. Their positions indicated also that the *c* axis and *h*00 planes of the apatite were parallel to the corresponding elements, respectively, of the original OCP. Present also were rather sharp reflexions of DCPA the positions of which indicated that the *b* axis and 00*l* planes of DCPA were parallel to the *c* axis and *h*00 planes, respectively, of the original OCP.

The patterns also contained diffuse streaks along the reciprocal lattice lines parallel to the reciprocal axis a^* of the original OCP. The streaks indicate the presence in the dehydrated OCP of amorphous, partially oriented, 'collapsed OCP layers' that remain after destruction of 'water layers' (preceding communication) of the OCP lattice. The diffuse streaks showed a two-fold symmetry about the *c* axis, in keeping with the pseudosymmetry of OCP, the 'apatite layers' of which presumably tend to persist in the collapsed lattice, and not with the hexagonal symmetry of HA. The intensities of the diffuse streaks indicated that the collapsed OCP layers comprised a considerable fraction of the dehydrated crystal.

Since DCPA was detected by the single-crystal method but not by X-ray powder diffraction, it is possible that DCPA has been present and overlooked in many apatitic materials. The strongest line of

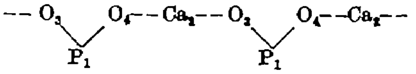
DCPA nearly coincides with the 002 line of HA or OCP which is frequently used to measure the particle size of apatitic material by line broadening. This measurement can be reliable only if DCPA, OCP and collapsed OCP are absent.

Results of previous studies[7] of dehydrated OCP were taken to indicate that the product was a defect apatite. The fact that OCP breaks down on drying into an apatite and DCPA, as shown by the single crystal X-ray investigation, makes it unnecessary to postulate the existence of a defect apatite, and the quasi-amorphous material, collapsed OCP, which is presumed to give rise to the diffuse streaks in the X-ray pattern, cannot properly be called hydroxyapatite.

The reasons for the orientations of the apatite and collapsed OCP relative to the original OCP crystals are apparent from structural considerations. The orientation of the DCPA relative to the original OCP crystal is understandable in terms of the three lattice elements of OCP (preceding communication) and DCPA (ref. 25) that lie in the plane of juncture; these are shown as follows:

OCP	DCPA
b = 9·63 Å	a = 6·91 Å
c = 6·88 Å	b = 6·66 Å
α = 89° 17′	γ = 89° 11′

Although the difference between b of OCP and a of DCPA precludes a normal epitaxy between the two compounds, there is a structural similarity which may orient the DCPA. In the notation of MacLennan and Beevers[26], DCPA has calcium phosphate chains of the type:



that are parallel to the b axis. These chains are similar to those parallel to the c axes in OCP and HA that involve the 'hexagonal' calciums (preceding communication). The ratio of the length of b of HA to that of a of DCPA is close to 3/2, which may be conducive to the orientation.

The zero-layer Weissenberg pattern of dehydrated OCP has strong reflexions with d values of $3{\cdot}37_5$, 2·70 and 2·25 Å on the central lattice line coinciding with that of the h00 reflexions of the original OCP. These spacings coincide almost exactly with the fourth, fifth and sixth orders of a 13·50-Å lattice spacing. This was first interpreted to mean that removal of the water had collapsed the OCP layers so that they had an average spacing of 13·50 Å instead of 18·68 Å as in OCP. It was found, however, that the $3{\cdot}37_5$- and 2·25-Å spacings could be indexed as the 002 and 003 reflexions, respectively, of DCPA, and the 2·70-Å spacing as the 300 reflexion of HA. The closeness of the fit shows that the thickness of the unit cell of HA, d_{100}, is very nearly equal to 5/6 of d_{001} of DCPA. The 002 and 003 reflexions of the DCPA component were relatively strong, and the possibility that some of their intensities arose from collapsed OCP layers with a spacing of 13·50 Å cannot be ignored.

HA and DCPA, the two crystalline phases in dehydrated OCP, are the stable solid phases at the invariant point near the water corner of the system $CaO–P_2O_5–H_2O$. Treatment of dehydrated OCP with boiling water then should cause these phases to increase at the expense of the amorphous phase, and, in accord with this, 6 h of this treatment sharpened the X-ray powder pattern of dehydrated OCP. This treatment of dehydrated OCP may be a method for preparing mixtures of HA and DCPA in which each particle would contain both phases. Such a product would be useful in studies of the uptake of phosphate by plants and in physiological studies because, according to the phase rule, the presence of the second solid phase reduces the number of degrees of freedom by one. We have no evidence of the formation of intracrystalline mixtures of HA and DCPA by direct precipitation or by hydrolysis of OCP; but, in view of the stability of the two solids, such mixtures should be anticipated.

Ignition at 500°–600° C converts DCPA to a pyrophosphate. The net process for OCP, then, could occur according to either of the equations:

$$4[Ca_4H(PO_4)_3 . 2{\cdot}5H_2O] = 2Ca_5OH(PO_4)_3 + 3Ca_2P_2O_7 + 11H_2O \quad (1)$$

$$4[Ca_4H(PO_4)_3 . 2{\cdot}5H_2O] = 4Ca_3(PO_4)_2 + 2Ca_2P_2O_7 + 12H_2O \quad (2)$$

Half the phosphate would be converted to pyrophosphate in the reaction of equation 1, but only a third in that of equation 2. Gee and Deitz[27] determined the pyrophosphate contents of several apatitic preparations with different ratios Ca : P that had been ignited at 600° C for 60 h. The experimental points shown in Fig. 2 of their paper are poorly represented by the line labelled 'equation 4' which corresponds, in effect, to our equation 1. They fall very close, however, to a line defined by the condition that all the OCP in the precipitates reacted according to equation 2. It appears from their results that little of the calcium pyrophosphate produced according to equation 2 reacted at 600° C. with the original HA (that is, in the HA layers) to form more tricalcium phosphate, but that this reaction did occur above 800° C. This behaviour is more readily understandable in terms of crystals which are interlayered than ones in which the acidic groups are distributed homogeneously in the lattice as they should be if the crystals were defect apatites or solid solutions.

Detection of octacalcium phosphate by X-ray diffraction. An unsuccessful attempt was made to use the intensities of the 100 (18·68 Å) and 700 (2·67 Å) lines in the powder pattern of OCP as quantitative measures of the amount of OCP in precipitates of intermediate composition. The intensities of these lines varied irregularly and disproportionately with change in the ratio Ca : P. For example, the pattern of a sample with mole ratio Ca : P of 1·52 contained neither line, whereas the 18·68-Å line was obvious in the pattern of a physical mixture of 5 parts of OCP and 95 parts of HA which had a mole ratio Ca : P of 1·65. Since these lines, which are the strongest lines distinguishing OCP from HA, did not appear in the pattern of a sample that contained about 50 per cent OCP, it is not surprising that OCP is not detected in bones and teeth from their X-ray patterns even if it is present.

The reasons for the faintness of the distinguishing lines of OCP are not far to seek. The lines arise from planes parallel to the platey direction of the crystals, so that the intensities of lines of very thin crystals, such as those in bones and teeth, would be expected to be low. Lamellation and twinning also are parallel to the platey direction, and so decrease further the effective particle thickness. Furthermore, loss of water from OCP crystals may also lower the intensity of the distinguishing lines.

Since X-ray powder methods are not reliable for the detection of OCP in its mixtures in poorly crystallized materials, suitable chemical or physical methods for its detection would be highly advantageous. Such a test might be based on differences in the reactions of OCP and HA with fluoride ions.

Infra-red absorption. Posner, Stutman and Lippincott[13] report infra-red absorption data on synthetic 'calcium-deficient' apatitic materials in which the intensity of the peak at about 3,400 cm^{-1} is inversely proportional to the ratio Ca : P. This relationship is interpreted to indicate that the positive charges of the missing calcium ions are supplied by hydrogen ions that form interphosphate hydrogen bonds in the apatite lattice. Winand, Dallemagne and Duyckaerts[11,16] disagree and state that the frequency of the absorption band is too high to be caused by a hydrogen bond of the type $O_3PO{-}H\cdots OPO_3H$; they suggest that the absorption is due to water adsorbed by the crystals.

An alternative explanation, which is consistent with interlayering in these materials, is that the intensity of the infra-red absorption peak is proportional to the amount of OCP in the preparation and so inversely proportional to the ratio Ca : P. Because of its water content, OCP has a broad absorption peak in the 3,400 cm^{-1} region[10].

Winand, Dallemagne and Duyckaerts[11] report a weak absorption at 2,400 cm^{-1} for some of their calcium-deficient apatitic materials. This absorption could be caused by the shortest interphosphate oxygen-to-oxygen distance in OCP which is 2·47 Å (preceding communication). Although these results indicate that the materials studied by Winand and co-workers contained OCP, the 2,400 cm^{-1} peak may have arisen from DCPA. Samples treated in a hydrothermal bomb[16] should not contain OCP, but may contain DCPA and HA.

Causes for low ratios Ca : P. It is apparent that at least two compounds, OCP and DCPA, are difficult to detect by X-ray powder diffraction in the presence of apatite, and each may contribute to low ratios Ca : P in apatitic materials. Collapsed OCP may behave similarly. The present results do not preclude the existence of calcium-deficient or defect apatites, occluded phosphate, solid solutions, or dubious crystalline compounds which have been suggested to explain the observed variations in the ratio Ca : P in apatitic materials, but to a large degree they make it unnecessary to hypothesize the existence of such materials. Surface adsorption certainly influences both the ratio Ca : P and the water content when the crystallites are small, as they are in bone and dentine. The crystals used in this investigation, however, were too large for the external surface to have had a significant effect.

The general formula for the unit-cell contents of calcium-deficient apatites, $Ca_{10-x}(H_3O)_{2x}(PO_4)_6(OH)_2$, given by Neuman and Neuman[6] has for $x > 0$ more atoms than can be contained in the unit cell of HA and, furthermore, is based on a degree of hydration of OCP that appears incorrect. The loss of two molecules of water for each mole of OCP postulated by them is in accord, however, with the reaction:

$$Ca_4H(PO_4)_3.2{\cdot}5H_2O = 3/2CaHPO_4 + 1/2Ca_5(PO_4)_3OH + 2H_2O \quad (3)$$

indicated by the single-crystal dehydration experiment described earlier. Dehydration experiments are difficult to interpret because of experimental ambiguity between waters of crystallization of OCP and non-essential water; the variability in the amount of water evolved when OCP is dehydrated, depending on whether the product contains collapsed OCP, HA and DCPA, or $Ca_2P_2O_7$ and $Ca_3(PO_4)_2$; and the uncertainty in the extent of reaction of hydrogen ions of the OCP layers with the hydroxyl ions of the HA layers. These factors prevent placing much reliance on dehydration experiments and probably account in part for the variation in the reported values for the degree of hydration of so-called tricalcium phosphate hydrate[15,20].

A general formula for lamellar mixtures of OCP and HA might be written as $Ca_{10-x}(PO_4)_6(OH)_{2-x}(H)_x.2{\cdot}5xH_2O$, provided it is not considered to represent an isomorphous series.

The several general formulæ proposed for these materials may be written $(10{-}x)CaO.3P_2O_5.nH_2O$, where n has the value 1 for the formula of Winand and Dallemagne[16], $(1 + x)$ for that of Stutman, Posner and Lippincott[14], $(1 + 3x)$ for that of Neuman and Neuman[6], and $(1 + 2{\cdot}5x)$ for the one we give above for lamellar mixtures of HA and OCP. In this formula, n includes both water of constitution and water of crystallization, and, in practice, some non-essential water may also be included. The value of n should be obtained, therefore, by difference after accurate analysis for calcium and phosphorus, and not by dehydration. In the foregoing form, the general formula clearly shows the inadequacy of the ratio Ca : P as the sole compositional description of apatitic calcium phosphates.

Crystallographic methods are unlikely to distinguish between HA, OCP, and lamellar mixtures of the two salts when the crystallites are as thin as 25–75 Å as they have been reported for bone[28,29]. These dimensions correspond to no more than five d_{100} thicknesses of OCP. It appears, therefore, that a comparative study of the chemical reactivities and solubilities of HA, OCP and their lamellar mixtures is one of the more promising means for gaining an understanding of the properties of biological and other cryptocrystalline apatitic calcium phosphates.

SOME POSSIBLE RELATIONSHIPS OF CARBOHYDRATES AND OTHER BIOLOGICAL COMPONENTS WITH THE WATER STRUCTURE AT 37°

By Dr. DONALD T. WARNER

Research Laboratories, The Upjohn Co., Kalamazoo, Michigan

IN two previous publications[1,2] some suggested conformations for polypeptides were discussed based on hexagonal arrangements of the carbonyl oxygens of the peptide bonds. One of the interesting aspects of these suggested hexagonal patterns was the very close correlation with a similar regular hexagonal arrangement of the 'second neighbour' oxygen positions in water at a temperature of about 37°. (My calculations were based on a 'first neighbour' oxygen distance of 2·93 Å at 37° as explained in ref. 2. Later, I found a brief mention by Brady and Krause[3] to a 'first neighbour' oxygen distance of 2·94 Å at 30°. This suggests a value of 2·95 Å at 37°, and would represent a 'second neighbour' oxygen distance of 4·82 Å in liquid water at this temperature, compared with our calculation of 4·79 Å.) Thus, a water layer lying over a peptide layer in this suggested conformation would have the possibilities for exact collinear hydrogen bonding between the respective oxygen atoms of the two layers at this temperature.

In view of these similar dimensions it seemed expedient to examine other biological substrates and see if their reactive groupings also permitted definite interactions with the water structure at about 37°. Because the conformations of the cyclitols have been extensively studied and are well defined, a specific example, *scyllo*-inositol, was selected to serve as a model for some of the interrelations which may exist. Many other substances have been studied in less detail, and I will mention some relevant points about them.

Scyllo-inositol and the water structure. *Scyllo*-inositol is a hexahydroxy *cyclo*hexane having the all-*trans* conformation with the six hydroxyl groups equatorial[4]. A model of this compound was constructed from the Dreiding stereomodels using the stable chair conformation for the *cyclo*hexane ring. (It was interesting to note that even in the models the boat form of *cyclo*hexane is non-rigid and allows considerable rotation around the bonds between carbons. However, once the model is forced into the chair form, this conformation is very rigid and allows no rotation about the carbon–carbon bonds. Only the hydroxyl hydrogens can rotate around the C–O axis.) The conformation of *scyllo*-inositol is given in Fig. 1. Measurements made on such a model indicate that the oxygen atoms 1, 3 and 5 form the corners of an equilateral triangle with sides which measure about 4·86 ± 0·02 Å on the Dreiding scale. This oxygen pattern has, therefore, approximately the same dimensions as the pattern formed by three 'second neighbour' oxygen atoms in the water structure at 37° (4·82 Å on a side). In a similar manner oxygen atoms 2, 4 and 6 form an equilateral triangle of the same dimensions.

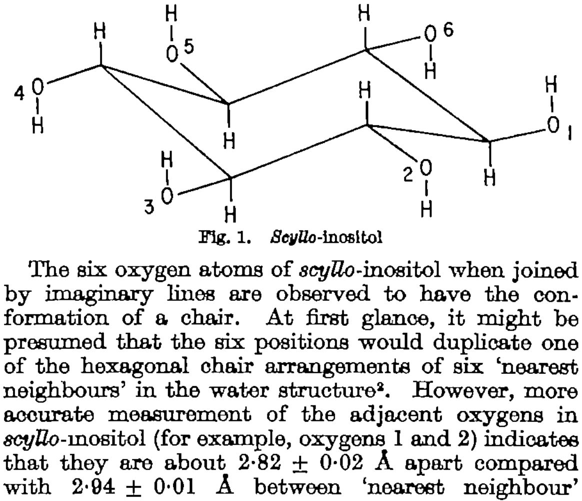

Fig. 1. *Scyllo*-inositol

The six oxygen atoms of *scyllo*-inositol when joined by imaginary lines are observed to have the conformation of a chair. At first glance, it might be presumed that the six positions would duplicate one of the hexagonal chair arrangements of six 'nearest neighbours' in the water structure[2]. However, more accurate measurement of the adjacent oxygens in *scyllo*-inositol (for example, oxygens 1 and 2) indicates that they are about 2·82 ± 0·02 Å apart compared with 2·94 ± 0·01 Å between 'nearest neighbour' oxygens in water at 37°. It was further observed that the respective 1–3–5 and 2–4–6 oxygen planes in *scyllo*-inositol are only about 0·48 Å apart, while the corresponding 'second neighbour' planes in water would be about 0·98 Å apart at 37° (Fig. 2, layers *C–D*, for example). The shorter distance between the oxygen layers in inositol and other sugars may bear some relation to the frequent occurrence of these compounds in nature as phosphate or sulphate esters; and the possibility should be kept in mind that the accommodation of these larger atoms into the water structure could require molecules with some alterations in the attaching positions to fit them into a possible stabilizing water pattern.

These possible interactions of inositols (and other sugars such as α- and β-D-glucose) with the water structure, especially with the 'second neighbour' pattern at 37°, indicate that such carbohydrates or their polymers could also interact in an orderly manner with peptide (or protein) layers arranged in

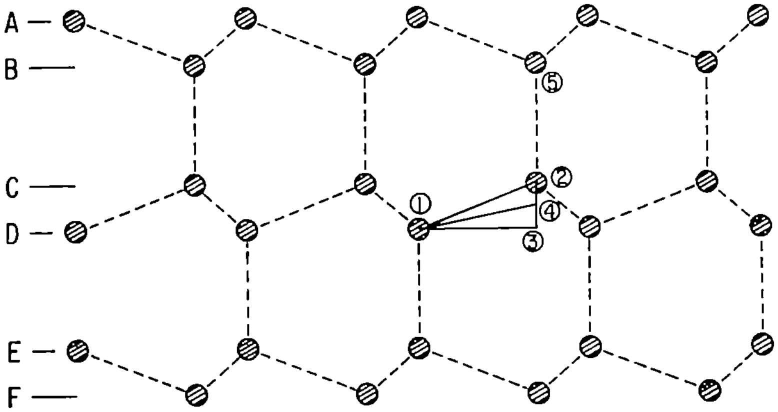

Fig. 2. Oxygen layers in the water structure (not to scale)

the hexagonal conformations which I have proposed[1,2]. In these conformations adjacent carbonyl oxygen atoms at the hexagonal corners are about 4·8 Å apart (with a possible 4·76–4·90 Å spread for the *cis-trans* interval as indicated in ref. 2); and any two corners and the hexagonal centre form an equilateral triangle with sides of about 4·8 Å. Therefore, hydroxyl groups 1, 3 and 5 of *scyllo*-inositol could form hydrogen bonds with two oxygens at hexagonal corners and have the third hydroxyl directly over a hexagonal centre. The presence of a phosphate ester, for example, on the third hydroxyl, would bring this phosphate directly over the hexagonal centre, which in some instances might have a serine hydroxyl present. (Using the Catalin space-filling models[1,2], it seems that phosphate fits well when centred over a hexagonal unit, particularly in units containing a single trans —N—H group (ref. 2, sec. 4) for bonding with the semipolar oxygen of the phosphate group. I have also looked at *myo*-inositol[4] fitted over such a hexagonal unit with phosphate on the axial hydroxyl, but exact measurements are difficult with space-filling models so this will be repeated if phosphorous atoms become available from Dreiding.)

The model also shows, as indicated in Fig. 1, that hydroxyl groups 1, 3 and 5 point upward as three parallel —O—H projection lines about 4·86 ± 0·02 Å apart. If the hydrogens of these three hydroxyl groups were bonded with three positions at similar 4·8 Å intervals (for example, two peptide oxygens and a hexagonal centre) the hydrogen atoms would be collinear with the bonded atoms for the strongest hydrogen bond[5]. The hydrogen atom could be furnished either by the sugar hydroxyl group or the enolic carbonyl of the peptide. In a similar manner the parallel projections of hydroxyl groups 2, 4 and 6, pointing downward as indicated in Fig. 1, could contact three similar positions below the *scyllo*-inositol ring. Recalling that my proposed peptide conformations allow hydrophobic and hydrophilic amide sides to the peptide structure[1,2], *scyllo*-inositol could bind two peptide layers above and below the *scyllo*-inositol ring through contacts with their respective hydrophilic amide surfaces.

Similar possibilities for bonding the hydrophilic amide surfaces of two peptide layers might be suggested for glycerol. In this molecule hydroxyls 1 and 3 can be arranged as parallel projections 4·8 Å apart, and the 2-hydroxyl group points in the opposite direction. Since the hydroxyl groups of glycerol (or *scyllo*-inositol or glucose), unlike the oxygen positions in water, will not vary appreciably in their separation distance with temperature, such bonds in glycerol could stabilize peptide structures at temperatures where uniform water contacts would be unlikely. The known utility of glycerol or glucose for stabilizing biological systems or viable tissues during freezing and thawing[6] could be partially explained by the suggested interactions based on our proposed hexagonal conformations.

We are now in a position to relate some of the observations on *scyllo*-inositol and peptides to a cross-section of the oxygen layers of the water structure as indicated in Fig. 2. This section[7] represents one of the possible edge-on views of the planar layers discussed in my previous article (ref. 2, plate 1), and each of the six layers of oxygen atoms represented by *A* through *F* would be a 'second neighbour' arrangement with the hexagonal patterns of water oxygens of ref. 2. At 37° ('nearest neighbour' oxygen in water = distance 1–2 = 2·94 ± 0·01 Å), layers *C* and *D* (or *A–B* or *E–F*) would be about 0·98 Å apart (distance 2–3) for the tetrahedral angle (109° 28′). Layers *B* and *C* (or *D–E*) would be 2·94 ± 0·01 Å apart (distance 2–5). If we now replace certain of these aqueous oxygen layers by my suggested peptide (or protein) conformations having similar hexagonal carbonyl oxygen patterns, the following results may be observed. Peptide conformations replacing layers *A* and *C* would have only a single 'second neighbour' aqueous oxygen layer, *B*, between them with a separation distance of 0·98 + 2·95 = 3·93 Å. The same distance would apply to each situation such as *B–D*, *C–E* or *D–F*, where two protein layers are separated by one 'second neighbour' oxygen layer. However, if the two peptide layers replace oxygen layers at intervals allowing two 'second neighbour' layers between, then the peptide layers may be separated by different distances. Thus, two peptide layers with their hydrophilic carbonyl oxygens in layers *A* and *D* (and their respective 'hydrophobic' or side-chain surfaces above and below these layers) would be about 4·91 Å apart at 37°, while two peptide layers replacing oxygen layers *B* and *E* would be about 6·88 Å apart. Although both the *A–D* and *B–E* peptide situations contain two 'second neighbour' aqueous oxygen layers between their carbonyl oxygen layers, the *B–E* situation could represent a possible interaction of water layers *C* and *D* with the enolized form of the peptide carbonyl groups, and the *A–D* situation suggests the interaction of the keto-form of the carbonyl oxygen with water layers *B* and *C*. If such possibilities exist, forces which might influence keto–enol transformations (for example, the transfer of phosphate from a sugar to a serine hydroxyl in the centre of a hexagonal peptide unit or vice versa) could conceivably operate to induce contractions or expansions between protein layers in liquid water.

If we consider the *A–D* and *B–E* peptide situations stabilized by water layers in Fig. 2, and attempt to fit the two 'second neighbour' oxygen planes of *scyllo*-inositol (1–3–5 and 2–4–6 oxygen planes, Fig. 1) into this water picture, then the distance between the planes and the general chair conformation is closer to the *C–D* spacing of water oxygens in the

B–E peptide situation. Referring to the triangle 1–2–3 in Fig. 2, with 'nearest neighbour' distance 1–2 = 2·94 ± 0·01 Å, and the angle 2–1–3 = 19° 28′, the projection of 2 on the *D* plane gives calculated values for the projection distance 1–3 = 2·77 ± 0·01 Å and for the interplane distance 2–3 = 0·98 Å. From the Dreiding models of *scyllo*-inositol it will be recalled that the distance between its two oxygen planes was 0·44–0·48 Å. Using the 0·48 Å distance and designating it as 3–4 on our small triangle (Fig. 2), the calculated distance 1–4 becomes 2·82 Å and the line 1–4 nearly bisects the 2–1–3 angle (angle 3–1–4 = 9° 48′, calculated). The distance 1–4 agrees well with the measured distance (2·82 ± 0·02 Å) between adjacent oxygens 1 and 2 in the models of *scyllo*-inositol, or what we might call the 'nearest neighbour' oxygens of *scyllo*-inositol. Since the points 5, 2 and 4 are apparently on the same straight line, it seems likely that *scyllo*-inositol is capable of maintaining approximately the same collinear hydrogen bonding possibilities between the suggested peptide layers *B* and *E* as would be afforded by water layers *C* and *D* at 37°, although the *B* and *E* layers could conceivably be about 0·5 Å closer together with *scyllo*-inositol. In this respect it is interesting to note that if hydroxyls 3 and 6 of *scyllo*-inositol (Fig. 1) are oxidized to keto-groups, then, in the resulting model, oxygens 1 and 2 (or 4 and 5) are now about 2·96 Å apart. (These estimates were measured from the chair form of the 3,6-diketo compound. The reference by Allinger and Freiberg[8] would indicate that in 1,4-*cyclo*hexanedione the boat form may predominate in inert solvents although no comment was made about interacting solvents, such as water.) This distance is very close to the 'nearest neighbour' oxygen distance in water (1–2, Fig. 2). At the same time the distances 2–4 or 1–5 in the 3,6-diketo-compound (cf. Fig. 1) are still about 4·84 Å apart, reasonably close to 'second neighbour' water oxygen distances. These four oxygens would then be capable of interchanging almost exactly with four water oxygens in the *C–D* layers (Fig. 2) although keto oxygens 3 and 6 would be far removed from their corresponding hydroxyl positions before oxidation.

General considerations. One other item in Fig. 2 may deserve special mention. The projection of oxygen position 2 on the *D* layer gives the distance 1–3 = 2·77 ± 0·01 Å. This distance is equivalent to the observed oxygen–oxygen distance in *ortho* dihydroxybenzenes (estimated at 2·76 Å, Drieding models) and may be very close to the oxygen–oxygen distance between enolic hydroxyls in vitamin C (2·78 Å from Dreiding models using conjugated carbon) or between adjacent methoxy oxygens in coenzyme *Q* (ref. 9). The distance between oxygens in *meta*-dihydroxybenzenes is about 4·76 Å in the Dreiding models. This is the same value as the calculated distance between the two carbonyl oxygens of a dipeptide bond in the *cis* configuration[2]. For a *meta*-amino-phenol the nitrogen–oxygen distance would be about 4·80 Å (Dreiding scale), and this may also represent the approximate distance between the 2-amino- and 6-hydroxy-groups in guanine. Therefore, these nearly planar aromatic systems with 1,2 or 1,3 substituents may also contain the possibilities for orderly interaction with our suggested protein conformations.

I have examined and measured other biologically active compounds, and in many instances the reactive groupings show similar interactions with the water structure. This present model of the water structure was made from the Dreiding tetrahedral carbon atoms, and as a consequence all measurements had to be transposed by a ratio of about 12 to 6·4 to fit oxygen distances in water. Trying to determine the position occupied by an entire steroid molecule, for example, under these conditions is very difficult, although the oxygen positions can be assessed. To avoid needless measurements and conversion errors, we have ordered appropriate tetrahedral atom units for assembling the oxygen positions of the water structure at 37° on the same scale as the other Dreiding models (1 cm = 0·4 Å) and complete with the resonating hydrogen positions on each bond. Not only will such a water model allow direct comparisons, but it will also enable one to assess more accurately the relation of axial hydroxyl groups in sugars, steroids and antibiotics to the water structure or my suggested peptide layers within that framework. It will also be interesting to see whether paraffinic hydrogens, for example, might interfere with the resonating hydrogen positions in the water structure at 37° and thus produce changes in the water stability at that particular site.

I would like to emphasize in conclusion that the measurements presented were made for the most part with the Dreiding stereomodels, and they are subject to inaccuracies inherent in the physical assembly and measuring devices[10]. However, the general results of the analysis of the *scyllo*-inositol case certainly suggest some interesting relationships with the water structure at about 37°.

These relationships have also permitted some speculations about feasible bonded interactions of carbohydrates with the peptide linkages of one or more peptide or protein layers in the conformations which I have proposed for consideration[1,2]. The bonded interactions are such that when small differences do occur in the measured oxygen–oxygen distances they are still within the limits of the 4·76–4·90 Å interval which was tentatively set up between adjacent carbonyl oxygens of a dipeptide for the *cis-trans* interval. In fact, small differences observed from the models may be real differences corresponding to preferential ability to react with *cis* or *trans* peptide arrangements. Such possibilities will certainly have to be kept in mind for amino sugars and amino-containing antibiotics where N—O or N—N distances might be slightly larger than the corresponding —O—O— distances in structures containing only hydroxyl groups, and —N—H distances in amino-groups are also slightly longer than —O—H distances in alcohols (Dreiding models). In a similar way a selected axial hydroxyl (for example, in *myo*-inositol versus *scyllo*-inositol) may set the stage for intra-layer instead of inter-layer reactions with protein or peptide surfaces. Our expanded model of the water structure should enable us to observe such three-dimensional differences directly.

I thank Drs. R. B. Kelly and P. F. Wiley for several helpful discussions on carbohydrate conformations and stability factors. I also thank Dr. E. L. Schumann for his advice.

Note added in proof. The water structure illustrated in Fig. 2 is based on the tetrahedral arrangement existing in the so-called hexagonal phase of ice. An arrangement corresponding to the diamond cubic phase of ice would also be possible. These two ice arrangements are discussed by Dowell and Rinfret[11]. An additional distinguishing feature of the two phases lies in the placement of six 'near neighbour' oxygens. In the ice hexagonal phase, six 'near neighbour' oxygens form chairs in one direction (for example, the horizontal dimension in Fig. 2) but boats in the other direction (the vertical dimension in Fig. 2). In the diamond cubic phase of ice, six 'near neighbour' oxygens always are present in the chair form. Cortisone, for example, shows different methyl group interactions with water arranged in these two possible phases.

POLAROGRAPHIC ACTIVITY OF PROTEINS AS A FUNCTION OF THE DILUTION OF AQUEOUS SOLUTIONS

By DR. LJ. ŠEVALJEVIĆ

Institute of Experimental Medicine MMA, Beograd, Yugoslavia

TROPP *et al.*[1] were the first to point out that the polarographic activity of proteins is considerably affected by the state of protein molecules in solution, namely, that increased dilution causes changes in the molecular structure of proteins, and the number of polarographic active groups. The possible reliable polarographic characterization of different proteins as resulting from this dependence was the subject of our investigations. In what follows I give the results of my efforts at polarographic characterization of α_2-globulins from guinea pig serum.

Investigations were made with guinea pig serum. Blood was drawn from the heart after fasting for 18 h, and centrifuged after standing at room temperature for 30 min. α_2-Globulins were separated by continuous electrophoresis (Shandon apparatus) in a borate buffer, *p*H 8·6, at 450 V. For testing the purity of the α_2-globulin fraction the eluates containing α_2-globulin and the corresponding sera were subjected to paper electrophoresis.

Eluates obtained by continuous electrophoresis were assayed for α_2-globulin by the micro-Kjeldahl method[2], and dilutions afterwards prepared containing 120, 200, 400, 600, 800 and 1,000 mg per cent.

Polarographic analyses were carried out using a radiometer Copenhagen *PO*3 apparatus. The basic electrolyte was aqueous solution containing equivalent ammonia, 0·1 equivalent ammonium chloride and 10^{-3} moles $[Co(NH_3)_6]Cl_3$. Into the polarographic vessel were placed 0·9 ml. basic electrolyte and 0·1 ml. α_2-globulin solution of known concentration. The potential applied between the electrodes was 1–2 V. The sensitivity of apparatus was 1/3,000, the dropping time of mercury 3·5 sec, at room temperature.

α_2-Globulins were eluted under the above conditions into two test-tubes (eluates I and II). The electrophoretic mobility of the respective bands of these eluates, namely, of the α_2-globulins from the corresponding sera, was identical. The polarographic waves of α_2-globulin, at concentrations studied, are given in Fig. 1. The average wave-heights are given in Table 1 and Fig. 2.

Polarographic analysis showed that the proteins in two eluates did not behave identically in some of considered concentrations. The average heights of polarographic waves of α_2-globulin in eluate I at concentrations 12, 20 and 40 mg per cent were higher than those of corresponding ones in eluate II (Table 1). The difference is statistically significant only at concentration of 20 mg per cent (P = 0·005).

The heights of the polarographic waves of α_2-globulin in both eluates increase with concentration rising to 20 mg per cent; after that they fall (Fig. 2). At concentration 40 mg per cent the wave height of the protein in eluate I is considerably lower than that at a concentration of 20 mg per cent ($P = 0·05$). This decrease becomes considerably slower as the concentration changes to 60, 80 and 100 mg per cent.

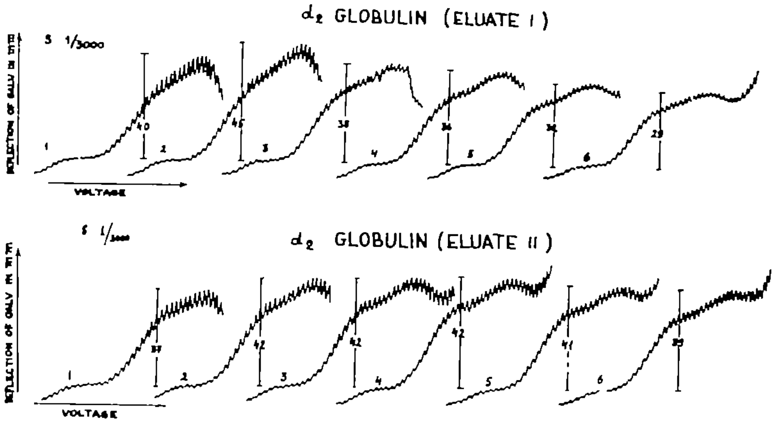

Fig. 1. Polarographic waves of α_2-globulins (eluates I and II) at concentrations. (1) 12; (2) 20; (3) 40; (4) 60; (5) 80; (6) 100 mg per cent. Initial voltage, −1 1 V

These results show that the polarographic activity of α_2-globulin falls as the concentration increases from 20 to 100 mg per cent, that is, in this region it is proportional to dilution. It follows that the number of groups capable of polarographic activity is higher in solutions of lower protein concentration. This phenomenon can only be explained by assuming that with the dilution the structure of the protein molecule changes, with the result that more hitherto inactive groups become free to react. Tropp *et al.*[1] also used

Table 1. AVERAGE HEIGHT (MM) OF THE POLAROGRAPHIC WAVES OF NATIVE α_2-GLOBULINS

Protein concentration (mg per cent)	12		20		40		60		80		100	
α_2 Globulins	M ± *S.D.*	*S.E.*	M ± *S.D.*	*S.E.*	M ± *S.D*	*S.E.*	M ± *S.D.*	*S.E.*	M ± *S.D.*	*S.E.*	M ± *S.D.*	*S.E.*
Eluate I	44·7±5·19	±1·84	49·0±3·65	±1·88	48·5±6·21	±2·35	39·5±3·31	±1·25	36·1±3·62	±1·37	34·1±3·76	±1·54
Eluate II	39·5±1·91	±0·72	43·4±2·76	±1·04	42·4±4·43	±1·37	40·0±5·72	±2·34	37·8±4·81	±1·97	33·0±5·56	±3·21

this hypothesis to explain the higher polarographic activity of certain dilute protein solutions. They concluded: "Welche Rolle das Wasser bei diesen Verdünnungserscheinungen spielt, wissen wir noch nicht sicher. Wir sehen jedoch, das jeder Verdünnungsgrad der untersuchten Eiweiß systeme polarographisch einen anderen Zustand des Eiweiß individuum aufzeichnet".

It is now known, however, that the stability of the secondary and tertiary structure of the protein molecule depends on its medium[3]. Media of high dielectric constant, for example, water, may cause a disruption of the hydrogen bridges of the protein molecule, and cause an unfolding of the molecule. The fact that this process implicates the liberation of the polarographically active groups may mean either that these groups were engaged in the formation of the secondary and tertiary structure or that they were unable to react owing to inaccessibility. The polarographic activity of α_2-globulin at high dilutions, namely, at concentrations of 12–20 mg per cent, was directly proportional to protein concentration (Fig. 2). This may mean that at such dilutions the protein molecule was unfolded, with all reactive groups free, so that the activity depended on concentration alone.

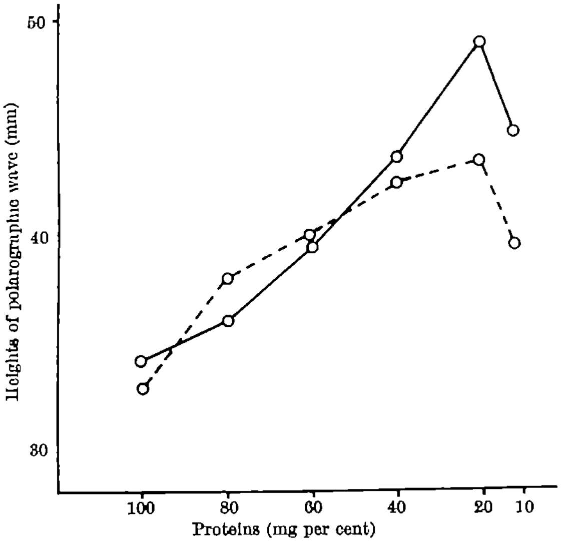

Fig. 2. Dependence of polarographic activity on the dilution of the α_2-globulin solution. —, eluate I; - - -, eluate II

It is now considered that the predominant force causing the folding of the protein molecule is the tendency of the non-polar amino-acid residue in the side-chains to assume the internal, hydrophobic part of the molecule, and the polar side-chains to enter the aqueous phase[4]. It might therefore be expected that at high dilutions the non-polar groups, including cysteine (considered mainly responsible for the polarographic activity of proteins), may appear at the surface of the molecule.

The two α_2-globulin eluates of identical electrophoretic mobility in a veronal buffer, *p*H 8·6, displayed different polarographic activity at certain concentrations. It is significant that this difference was most marked at higher dilutions (12–40 mg per cent). In view of the fact that these two proteins differ at lower concentrations in the number of groups available for polarographic activity, while at higher concentrations they appear to contain the same number of such groups, it follows that the number of structurally bound groups is higher in the latter case. This is only possible if different structures are involved.

UNITAGE AND SUGGESTED DESIGNATION OF ANGIOTENSIN ACTIVITY

By DR. PHILIP A. KHAIRALLAH*, F. MERLIN BUMPUS, IRVINE H. PAGE
and ROBERT R. SMEBY

Research Division, Cleveland Clinic Foundation, Cleveland, Ohio

BEFORE pure angiotensin[1] was available it was necessary to use arbitrary units of measurement to designate its biological activity. Several unitage systems were suggested[3,4,6,7,9,12,15–17], one no better than the other. They were based either on blood pressure increase in trained, unanæsthetized dogs or on comparison with the action of crude samples of peptide designated as 'standard' in anæsthetized animals or isolated muscle strips.

This multiplicity of units has led to confusion when attempting to compare data from one laboratory with those of another. The purpose of this article is to indicate, where possible, the relationships of different unitage systems to each other and to pure synthetic angiotensin. In the future, it is recommended that activity be designated in terms of weight of pure isoleucine[5]—or valine[5]—angiotensin II or the asparagine[1] derivatives.

Dog pressor assay[10], rat pressor assay[8,13], and isolated uterine and ileal myotropic assays[8] have been described. The preparation of the perfused rat hindquarters is a modification of a method by McQueen[11] and will be described in detail. Female rats (250 g) were killed either by a blow on the head or by ether. The abdominal aorta was quickly ligated just distal to the origin of the renal arteries. A nick was made distal to that. The aortic wall was elevated by a hook at the end of a 20-gauge needle, and the blood vessel cannulated almost to the bifurcation of the aorta. The inferior vena cava was then cut, and the hindquarters perfused with saline to flush out blood. This procedure took about 5 min. The rectum and uterus, after ligation, were removed, the rat transected at about the level of the third lumbar vertebra and immediately perfused at a constant rate by a Sigmamotor pump, with Krebs–Henseleit solution containing 10 per cent washed human red blood cells, and aerated with 95 per cent oxygen, 5 per cent carbon dioxide. Krebs–Henseleit solution alone led to rapid development of œdema, while the same solution containing dextran quickly abolished the vascular response. When 10 per cent red blood cell suspension was used, the preparation responded well for approximately 3 h, even though some œdema developed as shown by a doubling in weight. The rest of the procedure was identical with that use by McQueen[11].

---

* Established Investigator of the American Heart Association.

In a few experiments, hypertensive patients from the research ward of the Cleveland Clinic Hospital were used for assay. An 18-gauge needle was introduced into the brachial artery and connected to a Statham pressure transducer, model *P* 23 *D*. A slow infusion of 5 per cent dextrose in water was given intravenously through the contralateral cubital vein, and the angiotensin samples, diluted in 5 per cent dextrose in water, were rapidly injected via the infusion.

Three-point assays were conducted, as previously described for dogs[10], using a standard angiotensin preparation of Green and Bumpus[7] as a reference sample. This was then compared with different samples of synthetic isoleucine^{5}–angiotensin II synthesized in our laboratory[2], a synthetic sample of valine^{5}–angiotensin II, and four commercial preparations of asparagine^{1}–valine^{5}–angiotensin II ('Hypertensin', Ciba), lot numbers 32-654-1, *E* 6127 *B*, Prod. No. 8883.00 and 8595/8. The last four samples were kindly supplied by Dr. Schwyzer[17] of Ciba, Ltd., Basle, and were reported by him possibly to contain residual amounts of ammonium acetate. For this reason we have not expressed biological activities in terms of nitrogen content of the sample. The purity of the peptides was checked by paper electrophoresis. The strips were developed using 14·8-V/cm paper with a *p*H 2·1 formic acid–acetic acid buffer[19].

The pressor activities, expressed as Green and Bumpus units[7] per μg peptide, found for the different angiotensin preparations are presented in Table 1. Each figure in Table 1 is an average of 10–15 determinations with the standard deviation shown in parenthesis. Since the number of trials on human patients was limited (four experimental subjects), these results are presented as ratios to indicate only the relative activities of the different samples. As can be seen there is no difference between the valine^{5}– and isoleucine^{5}–angiotensin octapeptide, which agrees with the results reported by Schwyzer and Turrian[18]. The two peptides show no difference in the rat pressor assay, the dog pressor assay, the rat hindquarter assay and human assay. In contradistinction, some of the samples of asparagine^{1}–peptide show less activity than the aspartic^{1}–peptides. This difference may be due to differences in purity.

In an attempt to correlate the different unitage systems used, Dr. L. T. Skeggs kindly supplied a lyophilized sample of his standard, which he reported to contain 22 Goldblatt units[20]. Also, Dr. O. M. Helmer kindly supplied a solution which he reported to contain 10 Kuether and Haney units per ml.[8]. Other standard preparations used in earlier work[3,4,14,15] are no longer available.

Table 1

	Rat pressor*	Dog pressor*	Rat hindquarter pressor*	Ratio of human pressor†
Valine^{5}–angiotensin II	11·1 (±1·68)	9·5 (±1·36)	12·2 (±3·35)	1
Isoleucine^{5}–angiotensin II	11·4 (±2·02)	12·0 (±0·96)	12·0 (±2·12)	1
Ciba 32–654–1 asparagine^{1}–valine^{5}–angiotensin II	7·5 (±1·06)	7·2 (±1·92)	7·3 (±1·53)	0·83
Ciba *E*6127*B* asparagine^{1}–valine^{5}–angiotensin II	8·5 (±1·77)	8·8 (±0·26)	9·7 (±0·87)	0·87
Ciba 8883.00 asparagine^{1}–valine^{5}–angiotensin II	11·1 (±0·4)	10·1 (±0·3)	—	1
Ciba 8595/8 asparagine^{1}–valine^{5}–angiotensin II	8·5 (±1·22)	9·3 (±0·2)	—	0·87

* The activities are reported as Green and Bumpus units (ref. 7) per microgram peptide. The weight of the Ciba preparations was that reported on the ampule.

† These activities are reported as the ratio of each peptide to the activity of isoleucine^{5}–angiotensin II, which was set arbitrarily equal to 1.

From the average of four assays, one Green and Bumpus unit was found equivalent to 0·18 Goldblatt units. This is in agreement with data presented by Kuether and Haney[8], using a pithed rat preparation. From the average of seven assays, one Green and Bumpus unit is equivalent to one Kuether and Haney unit. These authors had reported that in the pithed rat preparation, one Green–Bumpus unit is equivalent to 1·16 Kuether–Haney unit. The ratio of the oxytocic unit of Schwarz, Masson and Page[16] to the Green and Bumpus unit was found to be 7·1 ± 0·2 in 20 comparative assays of isoleucine^{5}– and valine^{5}–angiotensin II. This ratio was found to be 7·7 ± 0·3 in 20 assays for asparagine^{1}–valine^{5}–angiotensin II. These ratios agree with the results previously reported[5]. Finally, the Paladini unit has been reported by him[12] to be equivalent to 0·0135 Goldblatt units.

Since synthetic angiotensin is now available, we recommend that investigators report the dosage of angiotensin in μg of synthetic valine^{5}– or isoleucine^{5}–angiotensin. 1 μg of pure angiotensin II is equivalent to about 12 Green and Bumpus units, 2·2 Goldblatt units, 12 Kuether–Haney units, and 163 Paladini units as average figures. Angiotensin is obtainable from Ciba under the trade name of 'Hypertensin. Ciba' which is asparagine^{1}–valine^{5}–angiotensin II, and contains an inert diluent. Of the four batches we have tested (Ciba Lot No. 32–654–1, No. *E*6127*B*, No. 8883.00, and No. 8595/8), three have shown about 75 per cent of the activity expected from the weight of peptide given on the vial. Electrophorograms of these peptides, shown in Fig. 1, indicate the presence of other peptides. One lot (Ciba 8883.00), containing mannitol as a diluent, showed biological activity similar to our purest synthetic angiotensin.

We suggest that since angiotensin amide is obtainable from Ciba this be used as a standard. We believe the homogeneity of such samples should be verified by paper electrophoresis as described here. We also recommend that all dosages be reported as μg of synthetic peptide, and the use of arbitrary units be discontinued.

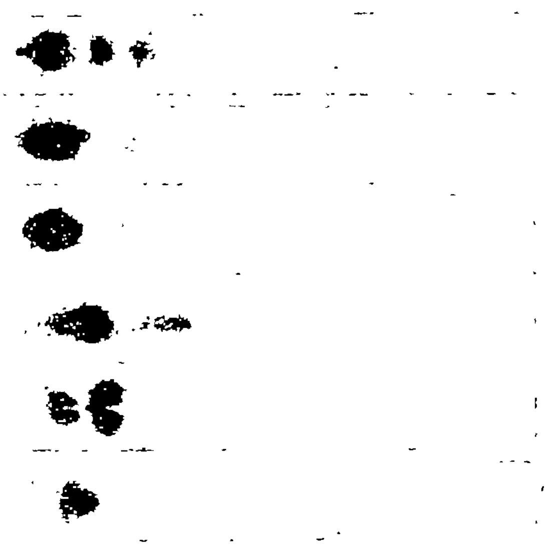

Fig. 1. Electrophoretic patterns of different angiotensin preparations

Top to bottom: (1) Val^{5}–angiotensin II amide (lot No. 32–654–1, Ciba); (2) Val^{5}–angiotensin II amide (lot No. 8888–00, Ciba); (3) Val^{5}–angiotensin II amide (lot No. 8595–8, Ciba); (4) Val^{5}–angiotensin II amide (lot *E*6127*B*, Ciba); (5) Val^{5}–angiotensin II (Ciba, reported by Dr. Schwyzer to contain a side-product, β-aspartyl–Arg–Val–Tyr–Val–Hist Pro–Phe–OH); (6) Ileu^{5}–angiotensin II (a preparation by Arakawa, ref. 2)

In a recent review, Schwyzer and Turrian[18] reported specific activities higher than we have been able to obtain. A synthetic sample of asparagine^{1}–valine^{5}–angiotensin II, assayed by Dr. Deodhar, Mount Sinai Hospital, Cleveland, Ohio, gave a figure of 3·3–3·5 Goldblatt units or 17·8–19·4 Green and Bumpus units/μg peptide. Another sample of the same peptide was reported by Schwyzer *et al.*[17] to have an activity of 4·8 Goldblatt units or 27·1 Green and Bumpus units. At present we have no explanation for these high and widely scattered figures, especially as we have repeated the assays in our systems, using the same peptide samples, and our results all fall within the range of biological variation. Skeggs[21] reported that angiotensin II prepared from horse blood, and purified by counter-current distribution to satisfy the criteria for a single substance, showed a biological activity of 2·4 G.U./μg. Schwyzer and Turrian[18] reported a value of 2·4 Goldblatt units or 13·3 Green and Bumpus units/μg in a sample of isoleucine^{5}–angiotensin II prepared according to Skeggs from horse plasma[20]. This seems to agree closely with the pressor activities we have reported.

This work was supported by the National Institutes of Health, grant No. *H*–96, and by a grant from the American Heart Association.

IN VITRO INVESTIGATIONS OF THE HUMAN CHORION AS A MEMBRANE SYSTEM

By Dr. F. C. BATTAGLIA and Dr. A. E. HELLEGERS*

Departments of Pediatrics and Gynecology and Obstetrics, Johns Hopkins University, Baltimore

AND

Dr. G. MESCHIA and Dr. D. H. BARRON

Department of Physiology, Yale University School of Medicine, New Haven

IN the course of investigations of the exchange of materials across the placenta we have been impressed by the need for a method by which we could quantitate *in vitro* the transfer and utilization of solutes by the specific placental membranes. Similar *in vitro* studies have been carried out by Ussing on frog's skin[1], by Garby[2] on human amnion, and by Crawford and McCance[3] on pig chorio-allantois.

The apparatus which we have found suitable for studies on the human chorion laeve and the inter-cotyledonary chorion of the sheep and goat is presented here.

As illustrated in Fig. 1, the apparatus consists of two cylindrical leucite blocks 75 mm in diameter and 25 mm thick. Into the opposing surfaces of each block a well has been cut, 32 mm in diameter and 5 mm deep, the membrane forming the common wall between these two wells or chambers. Each chamber communicates with a chimney (internal diameter

5mm holes
Three body-size 10/32 screw holes. Completely through piece
Three holes threaded through for 10/32 screws. To preserve clarity, these holes are not included in above view. To assemble the two halves, two inch long screws are required with wing nuts. Screws remain in this half permanently

Fig. 1. Line drawings indicate the form and dimensions of the two components that support the membrane for *in vitro* study

9 mm; overall height, 105 mm), by two holes each 5 mm in diameter, in the upper and lowermost part of their common wall respectively. The chimneys provide access to the fluid in each chamber for serial sampling and a means for equilibrating the media with appropriate gas mixtures. The gases reach the base of the chimney via a spinal needle (No. 22—4·5 in. long) sunk into the leucite block for convenience during sampling at an angle of approximately 30° to the chimney. Near its tip the needle is bent at a right angle to enter the chimney. As the gas bubbles escape from the tip they rise in the chimney and agitate the medium.

Because of the fragile character of the membranes, we have found it convenient to support them on a piece of fenestrated fibre glass filter paper. By tightening the three retaining screws (2 in. long with wing nuts), which bring the two leucite blocks together, the outer margins of the filter paper and the membrane are compressed and the rubber ring gasket seals the chambers from the outside. Within the bath the apparatus is supported on a metal rack by two prongs, 5 mm in diameter, which fit snugly into two sockets, one on the base of each block.

As the first step in mounting the membrane, 10–16 holes, each about 6 mm in diameter, are punched in a fibre glass filter disk (425 mm in diameter) of Whatman *GF/B*. The disk is then soaked in Gey's medium[4] and applied to the membrane, which is trimmed to fit it. After the membrane and fibre glass disk are in place within the rubber gasket, the two chambers are clamped and filled with appropriate solutions, care being taken to fill first that chamber to which the membrane is wholly exposed. This manœuvre forces the membrane against the supporting disk and prevents its rupture by hydrostatic pressure when the opposite chamber is filled. After measured volumes of fluid have been added to the chambers, usually 9 c.c. on each side, the apparatus is submerged to the level of the chambers' upper surface in a constant temperature bath. The spinal needles are then attached to plastic adaptors for the delivery of the gases for equilibration and mixing.

The following investigations of the *in vitro* properties of the human chorion laeve illustrate the usefulness of the apparatus and the appropriateness of the dimensions of the fluid-filled chambers for this type of tissue. The medium was always the bicarbonate buffered solution of Gey and Gey[4] equilibrated with 95 per cent oxygen and 5 per cent carbon dioxide at 37° C. The carbohydrates used were obtained from commercial sources and used without further purification. The methods described by Roe[5–7] were used for the determinations of *d*-xylose, *d*-arabinose, inulin and dextran. Glucose was determined by the method of Huggett and Nixon[8]. The placental tissue was obtained within 5 min of the delivery of the infant from uncomplicated normal pregnancies. The chorion laeve was stripped manually over a wide area from the underlying amnion. The chorion, thus free of both endometrial and amniotic components, was placed on the fibre glass filter paper.

(*A*) *Permeability of the chorion laeve to polysaccharides.* Three polymers were tested, inulin, dextran fraction '10' and dextran fraction '500'. In each case the solute was added to the 'maternal' side of the chorion. The concentration of the test substance in both chambers was determined at zero time and again at the end of a timed exposure period. The chorion laeve so tested is impermeable to each of the polysaccharides.

(*B*) *Uptake of d-glucose by chorion laeve.* *d*-Glucose was added to the medium to a concentration of 5·5 µM/ml. and the concentration in each chamber determined at half-hourly intervals after time zero. As the volume of fluid in each chamber at the beginning of the experiment was known and the volume of the serial samples was fixed, the utilization of *d*-glucose from each chamber could be calculated for each interval. The results in Table 1 demonstrate that the rate of glucose utilization by the membrane was the same on the fœtal and the maternal sides; there was no apparent polarity of the membrane with respect to this function. In addition, the rate of

Table 1. GLUCOSE UPTAKE OF HUMAN CHORION
(mg/g wet weight of tissue/h)

Half-h interval	By maternal surface	By fœtal surface
1	0·86	2·47
2	2·09	1·88
3	1·71	1·86
4	1·28	1·95
5	1·56	1·89
6	1·28	1·66
7	1·36	1·57
8	1·76	1·64
9	1·67	1·65
Average	1·51	1·56

glucose uptake remained relatively constant over the 4-h test period suggesting there was no decline in the activity of the membrane during incubation.

(*C*) *The movement of d-arabinose across the chorion laeve.* The usefulness of this technique for following the transfer of a non-utilizable sugar is illustrated by the results in Table 2. In this experiment the two chambers were filled with medium containing *d*-glucose at a concentration of 2·8 μM/ml. *d*-Arabinose was present in the chamber on the fœtal side at a concentration of 40 μM/ml. As the results in Table 2 demonstrate, there is a close correlation between the amount of *d*-arabinose lost in each ½ h of the 3-h incubation period from the chamber on the fœtal side and that gained in the one on the maternal; and as the final totals indicate the quantities lost and gained are virtually equal, the difference between the two is but 0·5 μM and within the error of the method of analysis.

(*D*) *The movement of d-glucose across the chorion laeve.* When a utilizable sugar is introduced into one of the chambers, its disappearance from that chamber can be compared with its appearance in the other, and the rate of its utilization by the membrane inferred from the difference. The results of two experiments for this purpose are illustrated in Table 3. In each case the *d*-glucose concentration on the maternal side was 40 μM/ml. In contrast with *d*-arabinose, there is a marked difference between the amount lost from the chamber on the maternal side of the chorion and the amount gained on the fœtal. In the two experiments reported here the amount of glucose utilized in the 2-h incubation period is quite similar, that is, 48·5 μM in the first and 45·5 in the second.

80–100		20·7
100–120	66·2	20·7

The results presented here demonstrate that when isolated in layers of cells the placental tissues can be studied *in vitro* by means of the technique described and that quantitative data may be obtained. The data indicate that over the course of a 5-h period consistent results can be obtained and satisfactory balance studies for a given solute carried out without the problems of improper mixing and non-representative aliquots or communications between the chambers and the external water bath.

The technique described appears to have a number of advantages that recommend its use for *in vitro* studies on fœtal and placental membranes, notably the absence of any unbalanced hydrostatic force on the membrane as it is supported. This feature is of particular importance for the membranes are quite fragile and easily torn, though they are readily available as tissue sheets.

EFFECTS OF INTRAVENOUS PHOSPHOLIPID CONTAINING PHOSPHATIDYL SERINE ON BLOOD CLOTTING WITH PARTICULAR REFERENCE TO THE RUSSELL'S VIPER VENOM TIME

By Dr. J. F. MUSTARD*, W. MEDWAY, H. G. DOWNIE and H. C. ROWSELL

Department of Physiological Sciences, Ontario Veterinary College, Guelph; Sunnybrook Hospital, Department of Veteran Affairs, Toronto ; Department of Medicine, University of Toronto

INVESTIGATORS have arrived at different conclusions concerning the effect of phosphatide fractions such as phosphatidyl serine on coagulation of blood[1–4]. The clotting time of plasma mixed with Russell's viper venom has been one of the tests frequently used for evaluating the effect of phospholipids on clotting of blood. In their original work, Barkhan, Newlands and Wild[1] found that concentrations of phosphatidyl serine, which accelerated the Russell's viper venom time, inhibited thromboplastin formation in the thromboplastin generation test. In this investigation, however, increased concentrations of phosphatidyl serine were found to inhibit the Russell's viper venom time. This evidence indicated that evaluation of the effects of phospholipids on blood clotting depends to some extent on the type of test used. Despite these findings, the Russell's viper venom time has frequently been used as a guide to whether a phospholipid promotes or inhibits clotting[4]. We have found in a study of the effect of intravenous phospholipid rich in phosphatidyl serine on clotting

of blood that when the majority of clotting tests are inhibited, the Russell's viper venom time is accelerated.

The phospholipid used in these experiments was prepared from beef brain essentially by the method of Folch[5]. Folch fraction III was then redissolved in anhydrous ether and reprecipitated with absolute methanol. This step was repeated 2–5 times. The re-extracted phospholipid fraction was then chromatographed and identified according to the method of Marinetti and Stotz[6]. Only one major spot was detected on the chromatogram when stained with rhodamine 6*G* or ninhydrin. When stained with rhodamine 6*G* and examined under an ultra-violet light, the spot gave a bluish purple fluorescence. This spot had the same R_F value as a standard sample of phosphatidyl serine. The phospholipid content based on phosphorus analysis by the method of Zilversmit and Davis[7] was 96 per cent. Although not conclusively shown, this phospholipid fraction is considered to be rich in phosphatidyl serine[8]. Analysis in a gas chromatograph showed the fatty acid composition of the phospholipid fraction was essentially as follows: stearic acid 54·8 per cent, oleic acid 37·2 per cent, eicosenoic acid 4·3 per cent, eicosodienoic acid 1·2 per cent[8]. This phospholipid fraction was found to inhibit the activity of clot promoting phospholipid in the thromboplastin generation test[8]. The clot promoting phospholipid used in the test system was prepared from beef brain cephalin and consisted of Folch fractions IV and V combined. This phospholipid, when used at a concentration of 250 μg in place of platelets in a normal thromboplastin generation test, gave a normal curve. The addition of 5 μg of the phosphatidyl serine-rich fraction to the clot promoting phospholipid in the thromboplastin generation test inhibited thromboplastin formation.

The changes in clotting were followed in anæsthetized beagle dogs (intravenous sodium pentobarbital) after intravenous injections of the phosphatidyl serine-rich phospholipid. The phospholipid used in the intravenous investigations was dispersed in imidazole buffer (pH 7·4) containing 2 mg/ml. sodium desoxycholate[9]. The dose given to each animal was between 30 and 50 mg per kg body-weight. The following clotting tests were performed using techniques that have been described[10]. The whole blood clotting time in glass and silicone-coated tubes, the prothrombin time, the prothrombin consumption time and the thromboplastin generation test. The Russell's viper venom time was done as described elsewhere[11].

Table 2. EFFECT OF INTRAVENOUS PHOSPHOLIPID ON THROMBOPLASTIN GENERATION

Thromboplastin generation mixture*	Incubation time (min) 1	2	3	4	5	6
	Substrate clotting time (sec)					
1 part normal Al(OH)$_3$-plasma diluted 1 : 5; 1 part test Al(OH)$_3$-plasma diluted as follow :						
Pre-injection undiluted	60·0	14·0	13·0	11·8	11·5	11·5
10 min post-injection undiluted	120·0	115·0	90·0	75·0	41·0	25·0
Pre-injection 1 : 5	45·0	13·8	12·0	11·8	11·0	11·0
10 min post-injection 1:5	120·0	59·0	24·0	15·0	18·0	16·0
Pre-injection 1 : 20	34·0	14·8	11·8	11·8	12·0	11·5
10 min post-injection 1:20	80·0	49·0	13·5	12·8	12·0	12·0
1 part hæmophilia *A* Al(OH)$_3$-plasma diluted 1 : 5; 1 part test Al(OH)$_3$-plasma as above:						
Pre-injection undiluted	60·0	23·0	11·5	12·2	12·0	10·0
10 min post-injection undiluted	120·0	80·0	32·0	50·0	20·0	20·0
Pre-injection 1 : 10	65·0	20·0	16·0	11·5	10·5	10·0
10 min post-injection 1 : 10	80·0	40·0	14·0	12·5	11·5	11·0

* The mixture was as follows: brain extract 0·3 ml.; normal dog serum diluted 1 : 10 0·3 ml.; 0·15 ml. of either normal or hæmophilia *A* Al(OH)$_3$-treated plasma; 0·15 ml. of test Al(OH)$_3$-treated plasma; 0·025 M $CaCl_2$ 0·3 ml.

In each of 15 experiments, the whole blood clotting time in glass and silicone-coated glass tubes was prolonged after infusion of the material (Table 1). In every case the prothrombin time was prolonged and the prothrombin consumption time shortened. In contrast, the Russell's viper venom time was accelerated on each occasion. There was a fall of about 30 per cent in the circulating platelet count. Studies using the thromboplastin generation test showed that the samples taken 10 and 20 min after the injection contained a factor present in the Al(OH)$_3$-treated plasma or non-absorbed plasma fraction which inhibited thromboplastin generation (Table 2). The inhibiting effect disappeared when the test plasma was diluted. The undiluted 10-min post injection plasma would not correct the defect in canine hæmophilia *A* Al(OH)$_3$-treated plasma when used in the thromboplastin generation test but the diluted test plasma would (Table 2). (The canine hæmophilia *A* plasma was supplied through the kindness of Dr. K. M. Brinkhous, University of North Carolina, Medical School, Chapel Hill.)

Two possible explanations for the discrepancy between the results for the Russell's viper venom time and the other clotting tests are: first, that the intravenous phospholipid infusion accelerated clotting producing a fall in platelets, factor V and factor VIII activity and other clotting factors consumed during coagulation; secondly, that while the intravenous phospholipid inhibited clotting in terms of the majority of the tests, its effect on the Russell's viper venom time in the dosage used was one of acceleration. The results from the present investigation do not give any support to the first explanation. There was no evidence of a reduction in factor VIII activity, and it seems unlikely that there was any loss in factor V activity since there was no prolongation of the Russell's viper venom time. Furthermore, the

Table 3. CALCIUM CLOTTING TIME*, SILICONED TUBES

	Proportions of mixtures					
Normal plasma	10	8	6	4	2	0
Test plasma	0	2	4	6	8	10
	Clotting time (sec.)					
Mixture of plasma tested:						
Normal and pre-injection	180	160	130	140	150	180
Normal and 10-min post-injection	180	210	320	320	540	580
Normal and hæmophilia *B*	160	140	150	160	170	708

* Test carried out as described by Biggs and Macfarlane (ref. 12).

prolonged prothrombin time was not corrected by the addition of 10 per cent of normal $Al(OH)_3$-treated plasma[8]. There was a marked diminution in prothrombin consumption without evidence of a marked fall in platelets or factor V and factor VIII activity. Addition of the 10-min post-injection plasma sample to normal plasma in various proportions produced inhibition of clotting in contrast to the effect of adding canine hæmophilia *B* plasma to normal plasma (Table 3).

It seems reasonable to conclude that, although the quantity of phospholipid given in these studies accelerated the Russell's viper venom time, blood clotting was inhibited as judged by a variety of other tests. This evidence from *in vivo* studies suggests that the Russell's viper venom time is of limited value in trying to assess whether a particular phospholipid fraction accelerates or inhibits blood coagulation. This conclusion would seem to be in agreement with the original findings from the *in vitro* studies of Barkhan, Newlands and Wild[1]. These results are also in agreement with the observations of Silver, Turner and Tocantins[9] that the intravenous administration of phospholipid rich in phosphatidyl serine has an anticoagulant effect.

ADVANTAGES OF IODINE-125 FOR STUDYING THYROID FUNCTION IN EXPERIMENTAL ANIMALS

By PROF. P. M. DANIEL, MURIEL M. GALE and DR. O. E. PRATT

Department of Neuropathology, Institute of Psychiatry, Maudsley Hospital, London, S.E.5

WE have found[1] that organic iodine-131, in the form of iodoprotein[2], is carried away from the thyroid gland in the lymphatics draining the gland. However, we felt that it was possible that the iodoprotein was leaking out of the thyroid follicles as a result of radiation damage to the follicles, in spite of the fact that the dose received by the thyroid (50–800 rads) was less than that which is generally believed to damage the gland[3]. We have therefore been using iodine-125 (which has recently become available from the Radiochemical Centre, Amersham, Bucks) instead of iodine-131 to label the iodine and it was thought that a comparison of the radiation doses given to the thyroid by these two isotopes would be of value. The radiation doses are determined to a certain extent by factors related to the size and to the irregular shape of the gland so that calculations have to be approximate. For the present calculation the thyroid gland of the cat has been taken as an example. Each lobe is approximately 2 × 0·6 × 0·3 cm and weighs 0·2–0·5 g.

The radiation doses given by the two isotopes (using the data[4] for emission energies, provided by the suppliers) can be compared as follows: for iodine-131 the mean β-emission energy absorbed by the tissue of the thyroid gland per decomposition (assuming that the average energy is 0·33 of the maximum energy) can be calculated to be 0·192 MeV. However, a proportion of this β-radiation escapes from the surface of the gland without being fully absorbed. A variable correction depending on the size of the tissue has to be subtracted from this figure. We estimate this loss to be of the order of 10 per cent of the β-emission energy for the thyroid gland of the cat, so that 0·173 MeV must be absorbed by the gland itself.

The internal conversion of some γ-energy to β-particles has to be taken into account. This yields a further 0·009 MeV, so that the total β-energy given to the tissue is 0·182 MeV. If the tissue contains 1 μc./g of a uniformly distributed β-emitter of long half-life, the dose-rate of ionizing radiation is 2·13 times the average energy (in MeV) absorbed per decomposition[5]. Therefore, the radiation energy delivered to the thyroid tissue by the β-emission of 1 μc. iodine-131/g is 0·388 rad/h.

The γ-energy delivered to the tissue is comparatively unimportant because the proportion absorbed is low, although this proportion is very much dependent on the geometry of the gland. The average γ-energy emitted per decomposition can be calculated from the data provided[4] to be 0·383 MeV. Using the figures which have been given[6] for γ-energy absorption in water and assuming that, for the cat, the average path of a γ-ray through the thyroid tissue is 0·3 cm, only about 0·75 per cent of the γ-energy is delivered to the tissue. Therefore, the total γ-energy emitted (0·383 MeV per decomposition) results in the delivery of ionization energy to the tissue at a rate of only about 0·006 rad/h for 1 μc. iodine-131/g.

The energy emission from iodine-125 is somewhat different. The β-emission is entirely due to a 93 per cent internal conversion of γ-energy and the energy of this β-emission is small, 0·008 MeV or less. The absorption of such low-energy β-radiation will be almost complete, even in a small gland. The effects of iodine-125 radiation on tissue have been discussed by Harper *et al.*[7]. In addition to soft β-radiation, a considerable part of the emission appears as very low energy *L*, *M* and *N* photons which are absorbed in the tissue very close to their origin and can be treated as β-like radiation. According to Harper *et al.*[7] the total energy of this β-like radiation is 0·021 MeV per decomposition. Therefore, 1 μc./g iodine-125 will deliver to the tissue a dose-rate of 0·0447 rad/h as β-like radiation. The rest of the radiation emitted consists of *K* photons and transition γ-radiation and the proportion which will be absorbed in the gland will be such that its contribution to the total dose cannot be neglected; but a considerable uncertainty is introduced here owing to the geometry of the gland. Full absorption of this γ-radiation and *K* photon X-radiation (taking its total energy per decomposition as 0·0413 MeV (ref. 7)) would mean that 1 μc. iodine-125/g of tissue would deliver energy at a rate of 0·088 rad/h. However, using the figures for γ-radiation absorption in water[4], and assuming that, for the cat, the average path of a ray through the thyroid tissue is about 0·3 cm, the proportion of the energy absorbed would be about 4·2 per cent and the energy actually delivered to the tissue would be only about 0·0037 rad/h. Thus, for a cat or similar animal, the total dose-rate to a thyroid gland which contains 1 μc./g would initially be about 0·394 rad/h for iodine-131 and about 0·048 rad/h for iodine-125. Therefore, if the same quantity of the two isotopes is injected into each of two animals, we estimate that the radiation dose given by iodine-125 over a given short period will be about 12·3 per cent of that given by iodine-131.

However, there are two other factors which must be taken into account in using iodine-125 and iodine-131. The first is that the effective biological half-life of iodine-125 is much longer than that of iodine-131 (about 27 days compared with 7 days, assuming a biological half-life for iodine in the thyroid gland of 50 days), though even for indefinite survival, an injection of iodine-125 will give to the thyroid a radiation dose of only about a half that of a similar quantity of iodine-131. The second factor is that iodine-125 is less convenient than iodine-131 for external *in vivo* counting. For *in vitro* counting, on the other hand, we have found that iodine-125 cannot be counted very efficiently with Geiger counters but by using an annular well-type NaI scintillation crystal counter (Ekco *N*618–651) we have obtained counting efficiencies for iodine-125 which are about three times greater than those for iodine-131. In addition, the slower physical decay of iodine-125 is often an advantage.

Table 1

For thyroid gland of cat	Approximate ratio $^{125}I/^{131}I$ For equal concentrations of radioactivity in the tissue	For equal counting-rates in the thyroid secretions
Initial radiation dose-rate	0·123	0·041
Total radiation dose	0·47	0·16

Lack of sensitivity of the radioactive assay procedure is often a limiting factor in biological work. Provided that a suitable scintillation counter is available, iodine-125 can be used, injecting less than one-third of the iodine-131 dose but still obtaining a comparable counting-rate, for example, in the thyroid lymph[2]. Such an injection will give, over a short initial period, only about 4 per cent of the iodine-131 radiation dose to the thyroid gland of a cat or other small animal and, even for indefinite survival, less than 20 per cent of the iodine-131 radiation dose to the gland. A comparison between the radiation effects of iodine-125 and iodine-131 on the thyroid gland of the cat is given in Table 1.

Therefore, in summary, we suggest that iodine-125 is likely to prove a valuable agent, particularly for non-survival experimental work in animals, since its unusually soft radiations make possible a high sensitivity of radioactive assay at a relatively low radiation dose to the thyroid gland. We have indeed found that iodine-125 is of much value in such work[2].

INFLUENCE OF RABBIT POLYMORPHONUCLEAR LEUCOCYTES AND MACROPHAGES ON THE IMMUNOGENICITY OF *ESCHERICHIA COLI*

By Prof. ZANVIL A. COHN
The Rockefeller Institute, New York

PREVIOUS studies from this laboratory have described *in vitro* systems in which the fate of micro-organisms can be determined within phagocytic cells[1]. These experiments as well as more recent ones on the degradation of isotopically labelled bacteria within both polymorphonuclear leucocytes and macrophages indicated that within 2–3 h of intracellular residence more than 50 per cent of the trichloroacetic acid-insoluble phosphorus-32 or carbon-14 of *E. coli K*-12 was broken down into acid-soluble fragments[2]. A comparison between the two types of phagocytes revealed that the macrophage brought about a more rapid and extensive degradation of *E. coli* macromolecules. The investigations reported here were conducted in an effort to determine the influence of intra-phagocytic residence on the immunogenicity of the same organism.

Rabbit peritoneal exudate polymorphonuclear leucocytes and macrophages were collected following the injection of 0·1 per cent glycogen-saline or mineral oil respectively. The cell suspensions contained either 99 per cent granulocytes or greater than 90 per cent macrophages. Reaction mixtures were prepared containing 36–40 × 10^6 leucocytes/ml., 10 per cent fresh rabbit serum and a multiplicity of 1–3 *E. coli*/phagocyte. The tubes were incubated at 38° C on an end-over-end rotator and aliquots of the suspension removed at time-intervals of up to 120 min. 1-ml. aliquots of the complete suspension were then injected intraperitoneally into 25 g *NCS* Swiss mice. Disruption of the leucocytes prior to injection did not influence subsequent agglutinin titres. Ten days after inoculation the mice were killed and individual serum samples obtained. The sera were then assayed

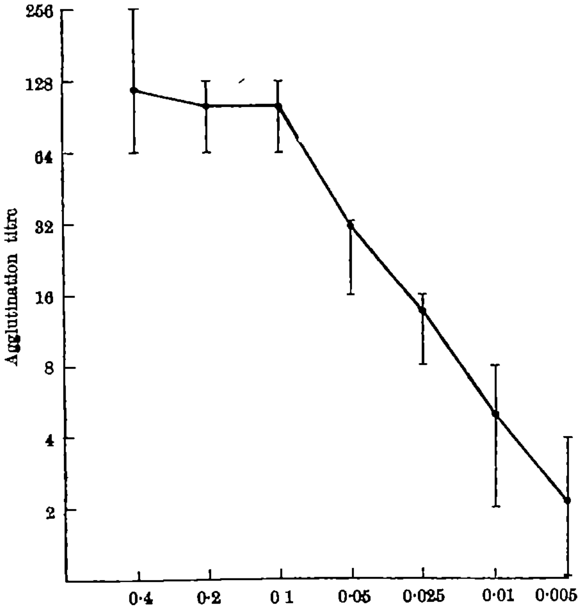

Fig. 1. Dose-response titration of *E. coli* injected intraperitoneally into *NCS* Swiss mice

for agglutinating antibody against a heat-killed (85° C/40 min) *E. coli* antigen. The rates of phagocytosis and intracellular killing were assayed on each of the incubation mixtures[1]. For each of the experiments described, more than 99 per cent of the organisms had been ingested and killed intracellularly after 20 min of incubation. This was the case with suspensions of either rabbit macrophages or polymorphonuclear leucocytes.

Initial experiments were performed on the immunogenicity of this strain of *E. coli*. Two-fold dilutions of a stock suspension of bacteria were prepared in pyrogen-free saline and injected intraperitoneally into mice. The animals were bled at 10 days and the results of the agglutination tests are shown in Fig. 1. Each point represents the mean titre of 15 animals. A relatively linear dose-response relationship existed between 0·1 and 0·005 ml. of antigen. Above this value the response became asymptotic with little increase in agglutinin titre. In all subsequent experiments 1·0 ml. of the phagocyte-*coli* suspension contained 0·1 ml. of antigen as defined in the titration experiment. This corresponded to a bacterial suspension having an optical density of 0·027 at 450 mμ with a 1·0-cm light path. Attempts at utilizing Gram-positive organisms, that is, *Staphylococcus albus* and *aureus*, *Bacillus subtilis*, for similar work proved unsuccessful since 10–100 times more bacteria were required to give a detectable agglutinin response. This number was too large to use in the *in vitro* phagocytic system and still get efficient ingestion.

Table 1. FACTORS INFLUENCING THE IMMUNOGENICITY OF *E. coli*

Pre-treatment prior to intraperitoneal mouse injection	Incubation time *in vitro* (min)	No. animals	Agglutinin titre (mean)
(*A*) *E. coli* + 10% NRS	120	12	115
(*B*) *E. coli* + 10% IRS	120	8	92
(*C*) *E. coli* + 10% IRS + PMN	120	15	3·8
(*D*) *E. coli* injected at 0 min, NRS + PMN injected 30 or 60 min later	—	10	112
(*E*) Heat-killed *E. coli* 80° C/30 min	—	18	118
(*F*) *E. coli* + 10% NRS + PMN, separated into:	60′		
1. Medium		6	< 2
2. 8,000*g* supernate		7	< 2
3. 8,000*g* pellet		7	32
(*G*) ΔK–*E. coli* + macrophages + 10% NRS	120′	12	110
(*H*) *E. coli* + macrophage + 10% IRS	120′	10	96

The influence of both the polymorphonuclear leucocyte and macrophage on the immunogenicity of *E. coli* is presented in Fig. 2. Each point represents the mean titre of 15 animals. At zero time, prior to the phagocytosis of the organisms, the titre of antibody was the same as that achieved with the administration of the bacteria alone. Thereafter, there was a progressive loss of immunogenicity of those organisms within polymorphonuclear leucocytes. After 120 min within the granulocyte the agglutinin titre of injected mice had been reduced to less than 1 : 4. In reference to the dose-response curve of Fig. 1 this corresponded to a 95 per cent decrease in the immunogenic mass of the bacteria.

The results obtained with the macrophage-*coli* mixtures were markedly different. In these circumstances there was no significant reduction in agglutinin response even after 2 h within the macrophage. Investigations have not been conducted at longer time-intervals. It should be stressed that the rate of ingestion, killing and degradation of isotopically labelled bacteria were the same in macrophages and polymorphonuclear leucocytes.

Table 1 illustrates additional studies with the same system. Groups *A* and *B* were controls in which normal and specific immune rabbit serum

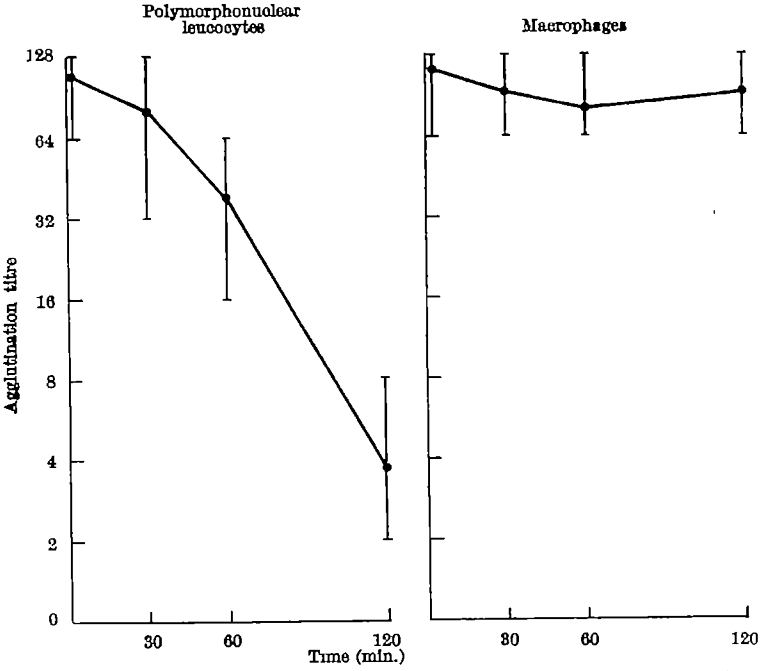

Fig. 2. Influence of intracellular residence within rabbit polymorphonuclear leucocytes and macrophages on the immunogenicity of *E. coli*

(NRS and IRS) did not alter the immunogenicity of the bacteria. The presence of immune serum in *E. coli*-leucocyte (PMN) suspensions (*C*) gave results similar to those obtained with normal serum. Experiments in which the equivalent number of leucocytes were injected intraperitoneally 30–60 min after the *E. coli* inoculum are presented in *D*. The results indicate that the rabbit cells have no influence on the antibody response of mice to *E. coli*. Group *E* shows that the use of heat-killed *E. coli* gave results similar to the viable organisms. Attempts to demonstrate the solubilization of the *E. coli* immunogen are shown in *F*. After 60 min incubation the leucocytes were centrifuged at low speed and the extracellular medium removed. The cells were then re-suspended in isotonic sucrose, homogenized and centrifuged at 8,000*g*. The residual immunogenicity was found in the leucocyte pellet, and no detectable activity was found in the soluble fraction or in the extra-cellular medium.

In view of the inability of macrophages to alter the immunogenicity of viable bacteria, additional investigations were carried out with heat-killed organisms and with viable bacteria in the presence of immune serum. Groups *G* and *H* reveal that under these conditions the macrophage was still not able to alter the agglutinogen.

The exact chemical nature of the agglutinogen of this strain of *E. coli* is not known. Preliminary observations on phenol–water extracts of the organism[3] showed that they were capable of interacting with immune mouse serum and removing agglutinating antibody. In this regard, it is likely that the somatic '0' antigens of Gram-negative bacteria are responsible for the evocation of agglutinins. Attempts at quantitating the amount of *E. coli* 'antigen' within leucocytes, by hæmagglutination-inhibition tests[4] with phenol–water extracts, have not as yet been successful.

It seems clear that a marked difference exists in the immunogenicity of *E. coli* after residence within rabbit granulocytes and macrophages. Whether this indicates a difference in the rate and extent of degradation of the responsible antigen within the two cell types is not clear. In view of the postulated role of the macrophage in preparing antigens for the stimulation of antibody synthesis[5], the formation of an immunogenic intermediate within these cells offers a second possibility. Irrespective of mechanism the results suggest that the antibody response of animals injected with certain micro-organisms may in part be related to the type of phagocyte population encountered *in vivo*. These results are in keeping with the previous data of Walsh and Smith[6] in their studies with *S. typhi*.

ELECTROPHORETIC INVESTIGATIONS OF A CLONE OF HAMSTER FIBROBLASTS AND POLYOMA-TRANSFORMED CELLS FROM THE SAME POPULATION

By J. A. FORRESTER and E. J. AMBROSE

Chester Beatty Research Institute, Institute of Cancer Research, London

AND

J. A. MACPHERSON

Medical Research Council Virus Research Unit, Institute of Virology, University of Glasgow

VOGT and Dulbecco have shown[1] that infection of monolayer cultures of hamster embryo cells with polyoma virus leads to the appearance of a new cell type which represents the tumour cell induced by the virus *in vivo*. Macpherson and Stoker demonstrated the same neoplastic transformation in clonal populations derived from a neonatal hamster kidney cell line (*BHK* 21), possessing many normal cell characteristics[2,3]. This system has obvious advantages for the examination of normal and cancer cells *in vitro*, and, since both the normal and transformed cells have the same rate of growth[3], comparisons may be made between cells of common ancestry and equal maturity. In previous work on the electrophoretic mobilities of normal and cancer cells[4] it was not absolutely certain that the normal and cancer cells compared were derived from the same cell type or that the higher negative charge shown by the cancer cells was not an expression of their more rapid growth. Eisenberg *et al.*[5] have shown that both neonatal and regenerating rat liver cells have an enhanced negative electrophoretic mobility, and that the greatest increase is correlated with the period of most active growth. However, in the case of liver cells, it has been shown recently[6] by Ruhenstroth-Bauer *et al.* that although the increases associated with regeneration and with malignancy are quantitatively similar, they are qualitatively different.

For the present investigation cells were grown as monolayers as described previously[2]. When nearly confluent they were re-suspended with trypsin and washed in complete medium. The cells used were those designated in the earlier communication as clone *C*13, and a transformed clone derived from them, *C*13 *TC*6. After transmission to the Chester Beatty Research Institute these cells were stored at 4° C and used within 2 days. It was found that storage for 6 days at 4° C did not affect the viability of the cells as judged by their lissamine green staining, their ability to grow on inoculation into fresh culture bottles and their behaviour when observed in a perfusion chamber on a microscope stage at 36° C. For microelectrophoresis the cells were washed thrice in 10 ml. of the electrophoresing medium, a solution 0·144 M in sodium chloride and 0·006 M in potassium chloride adjusted to pH 7·0 ± 0·2 with 0·15 M sodium hydroxide, and then re-suspended in this medium at a concentration of 4 × 10^3 cells/mm^3. The cells were introduced into an apparatus of the type described by Bangham *et al.*[7] using a micro-injection technique[8].

The results of electrophoresing three pairs of cell suspensions are displayed in the histograms of Fig. 1. Observations were made on 30 cells in the case of the normal clone and on 60 in the case of the transformed population. The C13 clone of normal hamster kidney fibroblasts behaves homogeneously in an electric field and the results obtained show a similar degree of homogeneity to that observed in erythrocytes[9] and rat thoracic duct lymphocytes[10]. The transformed clone, in contrast, shows a great heterogeneity with the emergence of cells of a higher mobility than those in the normal clone. The coefficient of variance in these populations is normally 10–15 times that of the normal clone. A similar or even greater scatter of mobilities is shown by some mouse ascites tumours[4] and by the pathological cell fraction in Hodgkin's disease[11]. The two hamster cell lines growing in parallel in logarithmic culture were first examined electrophoretically at the 160th generation and afterwards at the 280th and the 420th generations. The difference in behaviour was maintained over this period of propagation and is represented by the three pairs of observations recorded in Fig. 1. We hope shortly to examine cell lines as soon as possible after the transforming event so as to eliminate the effect of changes occurring as a consequence of prolonged growth in tissue culture.

It has been shown[6,8] that among the important ionogenic groupings situated at the cell surface are sialic acid residues derived from mucopolysaccharides and mucoproteins. In an attempt therefore to assess the types of grouping which might be responsible for the cell surface charge in the C13 and C13 TC6 clones cells were examined after treatment with neuraminidase. Suspensions of 6 × 10^6 cells in 1·5 ml. were incubated for 45 min with 500 units of neuraminidase derived from culture filtrates of *V. cholerae*. The purified, freeze-dried enzyme was very kindly supplied by Dr. G. L. Ada of the Walter and Eliza Hall Research Institute, Melbourne, and the incubation was carried out under the conditions described by him as optimal[12]. The cells were then washed twice and re-suspended for electrophoresis as before. Controls were performed with heat-inactivated neuraminidase.

The result of a typical experiment is illustrated in Fig. 2. These observations indicate that in both the normal and the transformed cell lines about 35 per cent of the surface charge arises from sialic acid groupings removable by bacterial neuraminidase. Sialic acid residues have been demonstrated to be important surface charge producing groups in several other cell types, including the human erythrocyte[13], the Ehrlich ascites carcinoma[14], rat liver cells and liver carcinoma cells[6], and the EL_4 leukæmia of mice[15]. Further, suspensions of C13 TC6 cells after incubation with neuraminidase are indistinguishable in the electrophoresis apparatus from cells of the normal clone after identical treatment. This suggests the possibility that associated with the malignant transformation there is a loss in quantitative control over the synthesis of some macromolecular component of the cell surface containing sialic acid residues.

A further species of charged grouping important in determining cell surface charge is the phosphate group derived from phospholipids. It has been shown elsewhere[8] that these groups may be detected by introducing calcium ions into the electrophoresing medium. Exposed phosphate groups have approximately one hundred times the calcium binding power of carboxylic groups and the cell negative mobility is correspondingly reduced by adsorption of these divalent cations. Experiments performed with the present cell system indicated that in both the normal and transformed clones about 20 per cent of the zeta potential is derived from such phosphate groups. In this case, however, the *C*13 *TC*6 cells electrophoresed in a medium containing 0·01 M Ca^{2+} showed the same heterogeneity as in the original determinations in media containing only monovalent cations, offering support to the hypothesis that the originally observed heterogeneity was due only to changes in the sialic acid-bearing components of the surface. These experiments are in agreement with the mosaic picture of the cell surface suggested by recent studies with the electron microscope[16]. Mucopolysaccharides, mucoproteins and phospholipids probably all contribute to the observed surface charge. The results also emphasize the importance of sialic acid groupings in determining cell surface charge, and indicate that a study of the changes associated with malignancy in sialic acid containing macromolecules may lead to a better understanding of the observed differences in social behaviour of malignant cells.

We thank Prof. M. J. P. Stoker and Prof. A. Haddow for their interest in this work. GROWTH MEASUREMENTS AND THE BIOLOGICAL INTERPRETATION OF MAMMALIAN GROWTH

By Dr. S. K. STEPHENSON

School of Rural Science, University of New England, Armidale, New South Wales

It has usually been assumed in the past that growth, or the increase in the size of animals, including mammals, is fundamentally some kind of multiplicative process. This concept has been derived from a consideration of the multiplicative nature of cell division, which is found, ideally, in a bacterial culture with an ample food supply. Also, it has been argued that secondary limitations and distortions can disturb this ideal multiplicative process, especially during the later stages of development, as a result of such factors as the limitation of nutrient materials in larger tissues, etc. In support of this concept, specific growth curves, discussed by Medawar[1] show a steadily decreasing rate of increase proportional to the mass already present, until growth stops as the mature size is reached. Further, Huxley's[2] allometry concept is based on the idea of growth as a fundamentally multiplicative process, although the allometry equation, $y = bx^k$, has been criticized since it was noted that the growth of certain tissues (for example, horn in mammals or shells in gastropods) appeared to be, theoretically, of an additive type.

Recently, fœtal growth patterns in Romney × Southdown cross and Australian Merino sheep have been examined[3,4], and the results from this work suggest a possible alternative to the multiplicative model for the biological basis of mammalian growth, at least during the pre-natal period of development.

Up until about 50 days after conception, the initiation (morphogenesis) of different tissues and parts of the body is taking place. From 50 to 140 days of fœtal age, however, the growth of the fœtus can be examined with a minimum of complications from changes in the external environment, and from changes in the internal endocrine hormone secretions, which are known to affect markedly the post-natal growth patterns although they do not appear to influence pre-natal growth to the same extent[5]. In addition, the fœtal weights increased from about 20 g to approximately 5 kg during this period and such a change, which was accompanied by marked alterations in the consistency of the organs and tissues of the body, should enable valid deductions to be made about the fundamental nature of mammalian growth during the pre-natal stages.

Fœtal weight showed the usual increasing exponential curvilinear relationship in the regression (line of best fit), on fœtal age, similar to post-natal weight changes with age prior to the point of inflexion at which the acceleration of growth becomes negative. In contrast to this pattern, the measurements of total body-length, such as straight or curved crown-rump-length, showed a linear relationship to increases in fœtal age. [Although data from other publications (for example, refs. 6 and 7) show that, prior to 50 days, a positive curvilinear increase in body-length is

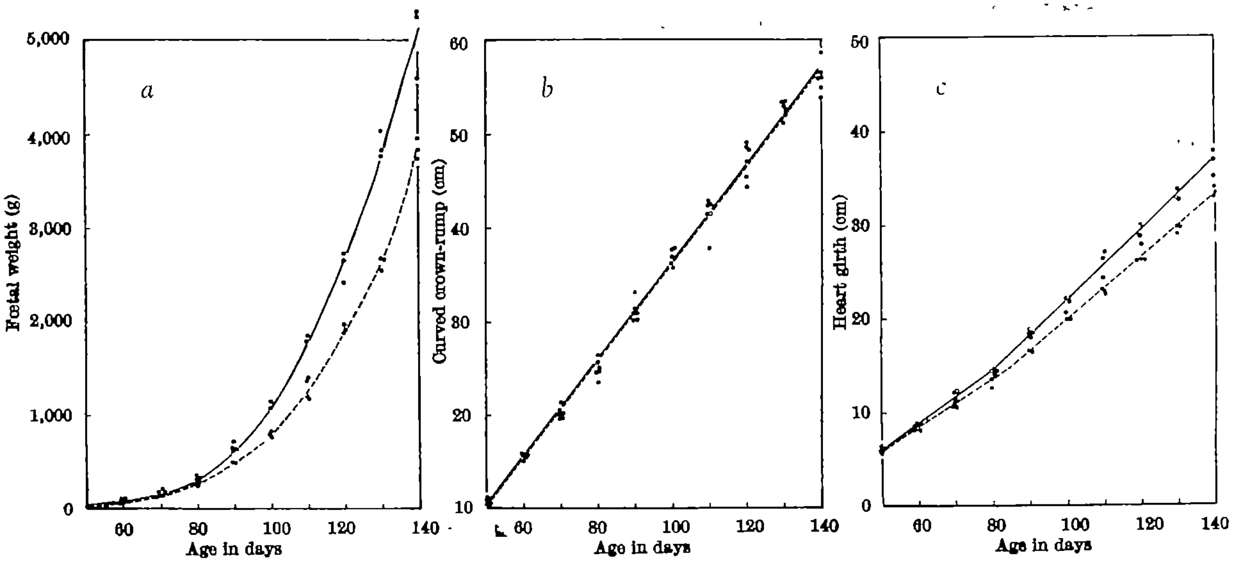

Fig. 1. Relationships between weight and age and the body-length measurements and age during pre-natal growth in sheep. ○——○, Romney × Southdown cross; ● - - - ●. Merino. *a*, Weight changes with increases in fœtal age; *b*, total body-length with increases in fœtal age. Single linear regression; *c*, heart girth with increases in fœtal age. Two linear regressions

obtained, this difference within the relationship between length and age is not unexpected for it is reasonable to suggest that the growth pattern may be different during the early stages of development.] Further, a series of 18 length measurements were taken over the surface of the body between certain fixed points, and apart from three minor exceptions, these also showed linear relationships in the regressions on fœtal age. There was, however, a marked change in the slope of several of these linear regressions at about 80 days of fœtal age, without any suggestion of a curvilinear relationship prior to or following this stage of growth. These changes in the slopes of the regression lines were most evident with measurements involving the head, the circumference of the front of the body and the lengths of the limb bones.

The general patterns shown by changes in weight and the surface-length measurements with increases in fœtal age are illustrated in Fig. 1.

The justification for these relationships has been fully discussed elsewhere[3,4]. The single linear regressions showed no obvious or systematic departures from this relationship when the means of the measurements for each age-group were plotted against fœtal age and in most instances these mean values were very close to the regression line[4]. Statistical tests were carried out to determine the significance of the x^2 terms in several of these regressions, but in all instances this component was not significant at the 5 per cent probability-level. Where two separate linear regressions were obtained, the standard errors of the regression lines showed that the change in slope was significant, at least at the 5 per cent level, but, except in three instances, there was no significant x^2 term in either of the two linear relationships. Once again, plots of the means of the measurements for each age group against fœtal age showed these values to be close to the regression lines, with no evidence of any systematic departures from the linear relationship. As a further test, where two linear relationships were obtained, the residual variances were compared with the residual variances after exponential and polynomial curves had been fitted to the data using an electronic computer. Except for two measurements of the circumference of the body, where growth results from the interaction of several different factors, the residual variances were higher after curves had been fitted and this result supports the hypothesis of a linear relationship between age and the length measurements.

The conclusion from this result is that, at 80–90 days after conception, the growth of the fœtus may change to a new constant pattern which is maintained until birth. In addition, the regression of the measurement of the length of the nose on fœtal age showed a significant curvilinear relationship up to 90 days with a positive x^2 term, but after this age the regression was linear and the slope of the line was lower than that during the first period.

These results suggest that, rather than being a truly multiplicative phenomenon, mammalian growth during the pre-natal period may be represented more accurately by the model of linear additions to existing material along the surfaces of a three-dimensional body, that is, a cubic growth pattern. Such a model should produce the weight and length changes with increases in fœtal age that have been found in this work, provided that the rate of addition of material at the surface may be altered to a new constant level at a certain stage during the growth of the fœtus.

Conversely, if a multiplicative process is assumed, it is unlikely that the decrease in the specific growth-rate is, by chance, just sufficient to give linear regressions of the surface-length measurements on age. A steady decrease in the efficiency of a multiplicative process, such as is suggested by the specific growth-curve, should produce a sigmoid shaped curve when the length measurements are plotted against fœtal age. Although a sigmoid curve may approximate closely to a linear model, especially if the point of inflexion occurs during the period at which the growth measurements are taken, there was no evidence of such curves in the investigation reported here. The increase in the fœtal weights and the marked alteration in the consistency of the organs and tissues of the body, from 50 to 140 days, should have an effect on the efficiency of a multiplicative process and produce some curvature of the length measurements.

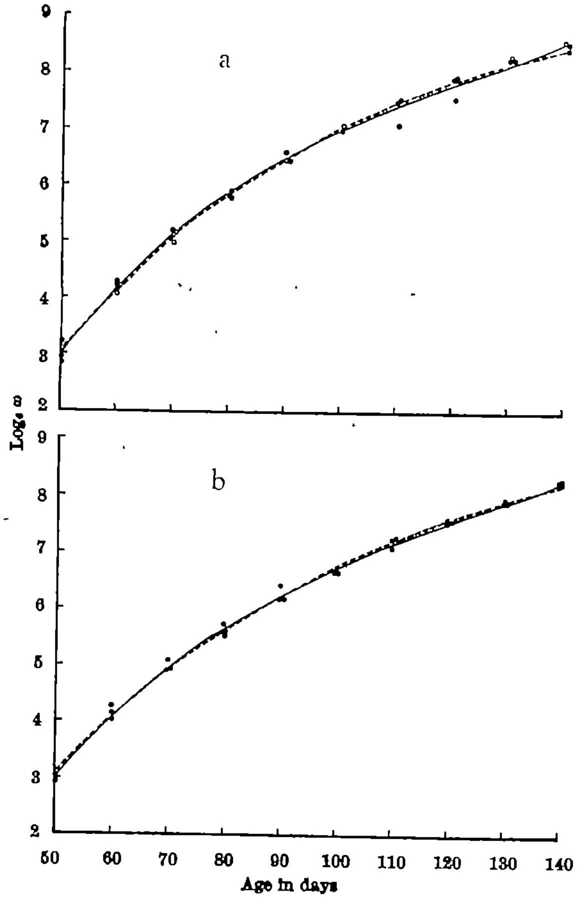

Fig. 2. Cubic and exponential equations fitted to the specific growth-curves for the Romney × Southdown cross (a) and Merino (b) fœtuses. —, Cubic curve; - - -, exponential curve

Other work supporting these relationships has been summarized by Brody[8]. Pre-natal increases in the sitting height of human fœtuses show a linear relationship to increases in fœtal age, while the corresponding weight increase is an exponential one. There is also evidence of a marked change in the growth pattern at about 18 weeks of fœtal age. Post-natal height increases in man, and increases in a number of different body-length measurements in cattle also show linear relationships to age during the juvenile growth period. In this connexion Brody[8] states that "weight (volume) growth prior to puberty tends to be self accelerating, that is, to grow in *geometric* progression —whereas linear growth, that is, terminal growth, tends to grow in *arithmetic* progression—and to plot linearly on arithmetic paper". In contrast to this pattern, post-pubertal increases in length measurements, and also total body-weight, show a declining exponential relationship to age, the equation relating weight or body-length, y, to age, x, during this period being of the form:

$$y = A - Be^{-kx}$$

Specific growth-curve and its relation to multiplicative and cubic growth models. The specific growth-curve shows a steady decrease in the relative rate of increase in weight, proportional to the mass already present, throughout the pre-natal growth period in the sheep[8,9]. Such a curve would result from either a multiplicative or a cubic model of weight increases with increases in fœtal age, and should be fitted by an equation of the form $y = a - be^{-kx}$ where y = weight and x = the age of the fœtus. An analysis of variance has been carried out to see whether such an equation does fit the data from the Romney × Southdown cross and Merino fœtuses and the results are given in Table 1 and Fig. 2. For comparison, a polynomial equation of the form $y = a + bx + cx^2 + dx^3$ has been fitted to the same set of measurements.

Table 2. EXPONENTIAL CONSTANTS AND EQUATIONS RELATING WEIGHT, w, TO TOTAL BODY-LENGTH (L) MEASURED AS STRAIGHT OR CURVED CROWN-RUMP

* Significant at 1 per cent level. † Significant at 5 per cent level. ‡ Data from ref. 9. § Equations calculated by Malan and Curson (ref. 15). N.S. Not-significant.

It is seen that both the exponential and polynomial equations fit the data within the 5 per cent probability limits determined by the within age group variance, although for both the Romney × Southdown cross and Merino results the polynomial equation gives a slightly better fit than the exponential, mainly as a result of the high mean values for fœtal weights at 140 days.

Other relationships affecting the multiplicative or cubic interpretation of mammalian growth. Additional information can be obtained from the length/weight relationships in different breeds during the fœtal growth period, from the regressions of the $\sqrt[3]{\text{body-weight}}$ on fœtal age and from a study of the growth of individual tissues, particularly bone and muscle, which make up a large part of the weight of the fœtus.

Fœtal weight should be a function of (body-length)^3 if growth is uniform in all directions and if the specific gravity of the body remains constant during the growth period. The exponential constant relating weight to total body-length can be obtained from the linear regression of $\log_{10}$ weight on $\log_{10}$ length and these constants are given for several different breeds during the pre-natal growth period, in the equations relating to two variables in Table 2.

The average of these exponential constants is approximately 3·0; but there is some variation away from this mean value and statistical tests show this variation to be significant. The value of the exponential constant is correlated with the carcass conformation of the different breeds, for, as shown in Table 2, it tends to be higher in breeds improved for mutton production. Such breeds show a greater breadth and circumference of carcass for a standard body-length[4] and as growth in width is more rapid in these breeds, relative to growth in length, it is reasonable that the exponential constant relating weight to length should be higher. This point is stressed by the differences between the exponential constants, obtained when straight or curved crown-rump are used as the measure of total body-length. As age and weight increases, straight crown-rump increases at a greater rate than curved crown-rump on a $\log_{10}$ scale with the data included in these results, hence the resulting exponential constants are lower than those obtained with curved crown-rump. In addition, it is possible that changes in the specific gravity of the carcass during the pre-natal growth period may be greater in the breeds improved for mutton production.

The cube roots of fœtal body-weight increase with age according to the relationships shown in Fig. 3 and Table 3.

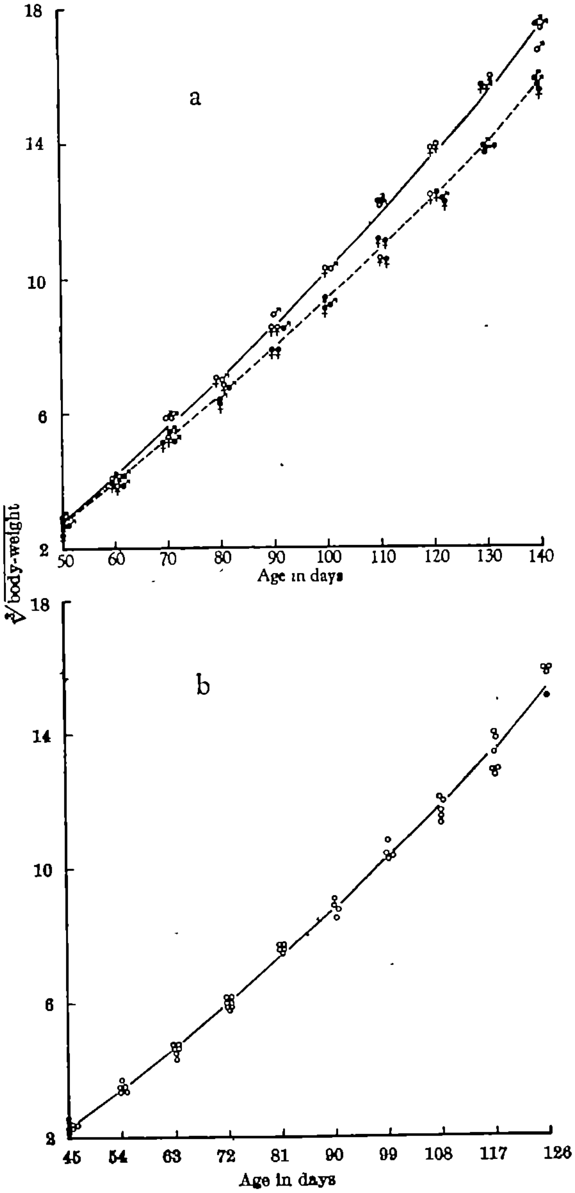

Fig. 3. Regressions of $\sqrt[3]{\text{body-weight}}$ on fœtal age. *a*, Romney × Southdown cross, – ♀♂ – and Australian Merino, - - -♀♂- - -; *b*, New Zealand Romney

If growth occurs through linear additions to existing material along the surfaces of a three-dimensional body, then the cube roots of body-weight should be linear with age provided that no changes occur in the specific gravity of the material already produced and provided that all growth-rates at the surfaces remain constant. The surface length measurements, however, show that, at least for some parts of the body there is a marked change in the growth-rate at about 80 days although the rates are constant before and after this age. Conversely, the cube roots of body-weight show a significant curvilinearity in the regressions on fœtal age for the Romney × Southdown cross, Australian Merino and New Zealand Romney breeds. This curvilinearity is not produced by a sudden change in the slope of a linear relationship at about 80 days, but is a gradual trend over the whole age range studied, and it is found in the New Zealand Romney data if the points below 54 days are excluded from the analysis. The Australian Merino data do not show a greater curvilinearity than the Romney ×

Table 3. EQUATIONS FOR THE REGRESSIONS OF $\sqrt[3]{\text{BODY-WEIGHT}}$, y, ON FŒTAL AGE, x, AND F VALUES GIVING THE SIGNIFICANCE OF THE x^2 TERM

Breed	Equations	Age period	F Value giving significance of x^2 term
(i) Romney × Southdown cross	$y = -3{\cdot}2614 + 0{\cdot}104985x + 0{\cdot}00029657x^2$	50 to 140 days	7·338 (1;26d.f.)*
(ii) Australian Merino	$y = -2{\cdot}58015 + 0{\cdot}094387x + 0{\cdot}00025133x^2$	50 to 140 days	21·97 (1;26d.f.)†
(iii) New Zealand Romney	$y = -2{\cdot}194834 + 0{\cdot}079416x + -0{\cdot}0004694x^2$	45 to 126 days	35·856 (1,53d f.)†

* Significant at 5 per cent level. † Significant at 0·1 per cent level.

Southdown cross results, as is suggested by Table 3, for the error variation about the regression line is much higher in the latter group.

This result is not consistent with a cubic growth model unless there is a change in the rate of increase during the growth period or unless there is a change in fœtal density. Fœtal density increases from about 1·03 to 1·06 between 50 and 140 days after conception[10], but this increase is not sufficient to account for the curvilinearity of the regressions. Alternatively, changes in the growth-rates, which occur at slightly different ages in different parts of the body, the different allometric growth-rates in different regions, or interactions between these two effects, could produce a curvilinear relationship between age and the cube root of fœtal weight.

Conversely, the growth of certain tissues or parts of the body may conform to a multiplicative model. Although this is not consistent with the pattern shown by the majority of the length measurements, these do not cover all parts of the body and, in addition, three length measurements do show slight curvilinear relationships in the regressions on fœtal age.

Tissue growth. Growth studies of the individual tissues should provide evidence for the interpretation of mammalian growth as a multiplicative increase in size or as an addition of new material along the surfaces of a three-dimensional body. Except for bone, hair (or wool) and horny structures produced by the epidermis, however, not enough is known of the growth of individual tissues to determine whether it is of a multiplicative or additive type. It has been suggested[11] that new muscle cells are not produced after the middle stages of gestation (about 90 days in the sheep), but the physiological aspects of subsequent increases in the size of the muscle fibres are not precisely known. Mitotic activity in the central nervous system after neurulation appears to be confined to an inner 'germinal layer' lining the central canal and brain ventricles[12], but changes in cell size, the migration of nerve cells and regional variations in mitotic activity all affect the growth pattern.

It has been known for some time, however, that the growth of hair, wool and horny structures produced by the epidermis is of an additive type. The growing region for these tissues consists of a layer of actively dividing cells, and once new cells are produced from this mitotic region, keratin formation transforms them into non-living products of the 'germinal layer'. The growth of bone, which controls to a greater or lesser extent the growth of several other tissues (notably muscle, for example, ref. 13), and has a marked influence on the size and shape of the animal, is known to occur through additions of new material at the bone surfaces and through increases in length by mitotic divisions in the epiphyseal plates[14]. Therefore, apart from the secondary resorption which occurs during growth so that the correct shape of the bone is maintained, the growth of this tissue can be said to follow the model of additions of new material on the surfaces of a three-dimensional body.

Finally, it must be emphasized that a simple theoretical model, consistent with all aspects of growth, is unlikely to be produced. General considerations lead to the conclusion that growth processes may be too complex to allow the use of one mathematical generalization to describe them. The arguments presented in this article do indicate, however, that the overall patterns of increase in body-size may conform more closely to a cubic, than to a multiplicative model during the mammalian pre-natal growth period, and also possibly during the juvenile growth period. This may, in turn, reflect the importance of bone growth in determining such increases in body size.

A NEW ORNITHISCHIAN FROM THE UPPER TRIASSIC OF SOUTH AFRICA

By Dr. A. W. CROMPTON

South African Museum, Cape Town

AND

Dr. A. J. CHARIG

British Museum (Natural History), London

An important discovery made by the 1961–62 British–South African Expedition to the Upper Triassic rocks of South Africa and Basutoland was the partial skeleton of an ornithischian dinosaur, including the almost complete skull and lower jaw. Ornithischian remains are very rare below the Upper Jurassic; indeed, the only ornithischian material yet described from the South African Karoo, or from Triassic rocks of any age, is one very incomplete skull (*Geranosaurus atavus* Broom 1911 [1]).

The new skull (Fig. 1*A*) is almost complete but slightly crushed. The bones are covered by a thin, very hard ferruginous layer which can be removed only with the aid of a small diamond saw. Although, as yet, only the anterior region has been prepared in this manner, the general outline of the whole skull is nevertheless apparent and is shown in Fig. 1*A* by dotted lines. Complete preparation of the specimen, especially of the brain-case, will take a very long time; it has therefore been decided that a preliminary description of the skull and lower jaw should be given now, and that, for convenience, the specimen should be named.

Order: ORNITHISCHIA

Genus: *Heterodontosaurus* nov.

Derivation of name. In reference to the differentiated dentition, unexpected in an ornithischian.

Type-species. Heterodontosaurus tucki sp. nov.

Diagnosis. As for *H. tucki*.

Heterodontosaurus tucki sp. nov.

Derivation of name. In recognition of the generous help afforded to the Expedition by Mr. G. C. Tuck, managing director of the Austin Motor Co. of South Africa (Proprietary), Ltd.

Material. Only the holotype in the South African Museum (Catalogue No. *K*337), consisting of skull, lower jaw and post-cranial remains.

Horizon. In the transitional beds of the Cave Sandstone[3], below the basalt; probably of Upper Keuper age.

Locality. At an altitude of about 6,200 ft. on the mountain behind Tyindini trading store, in the district of Herschel, Cape Province, South Africa.

Diagnosis. Ornithischian with short facial region, large antorbital fenestra, and supraorbital bone projecting into orbit. Hinder part of premaxilla with three teeth of carnivorous type, the third large and caniniform; wide, deep diastema followed by about 12 close-set, highly specialized teeth in maxilla, ridged vertically in their distal halves. Predentary without teeth; first tooth on dentary large, caniniform, projecting upwards into diastema; other teeth on dentary close-set and similar to those in maxilla.

Skull. The skull is about 92 mm long, with a large antorbital fenestra (Fig. 1*A*, *ANT.F.*). The premaxilla (*PM.*) is deep below the external nares; the nasal is rather bulbous; and there is a supraorbital bone (*S.*) projecting backwards into the orbit from its anterior margin. Through the thin layer of matrix it may be recognized that the jugal possesses a flange (*J.F.*) below the lateral temporal fenestra and that the squamosal extends backwards beyond the posterodorsal corner of the quadrate.

Lower jaw. There is a small predentary at the front, separated from the dentary by a distinct suture. Behind this suture, and running dorsoventrally immediately below the first mandibular tooth, is a distinct groove; this may have served to accommodate the hinder end of the horny beak which probably covered the predentary. The lower jaw appears to have a well-developed coronoid process.

Upper teeth. The front part of the premaxilla is without teeth, but the hinder part bears three. All three are laterally compressed and slightly recurved. The first two are incisor-like, the second larger than the first; the third is much the largest and resembles the canines of therapsids and mammals. A wide bay-shaped diastema separates the premaxillary teeth from the maxillary teeth.

There are 12 teeth in the maxilla, closely packed together in a single row 31·5 mm long; their alveoli lie medially of the lateral surface of the bone. They have very long column-shaped crowns, which, seen from the side, are a little wider distally than at the alveolar border, and which curve inwards a little below. The anterior teeth are laterally compressed and possess a sharp distal cutting edge. The posterior teeth are thicker medio-laterally than the anterior and possess a correspondingly wider occlusal surface; they probably served to crush the food. The lower edges of all these teeth are more or less level, apparently because of wear; this is shown particularly well on the left side. (In Fig. 1*B* the occlusal surface has a slightly irregular appearance because the crowns of the right maxillary teeth have suffered a little damage at their distal ends.) Enamel is present on only the distal half of the outer surface of each crown, the enamelled surface being divided into two smooth depressions by a vertical ridge down its centre. The first four maxillary teeth have also secondary vertical ridges, anterior and posterior to the main ridge. This ridging produces a strikingly characteristic appearance.

Lower teeth. The predentary is without teeth. The first mandibular tooth lies near the front end of the dentary and fits into the diastema in the upper jaw; it has the shape of the canine present in therapsids and mammals, being slightly recurved, and a serrated posterior edge. Five or six mandibular teeth behind the 'canine' are missing; but seven of the mandibular teeth are fairly well preserved, and have been exposed in medial (Fig. 1*C*) and partially in lateral view. As in the case of the corresponding upper teeth, the crowns are high. Enamel seems to be present only on the inner surface, which bears a vertical ridge not far behind the anterior margin of the crown and an additional ridge farther back. This internal view of the lower teeth shows no replacement teeth at their bases.

Affinities. Differentiation of the dentition into incisor-like, canine-like and post-canine-like teeth is uncommon in animals other than therapsid reptiles and mammals.

The following characteristics, however, taken together, indicate that *Heterodontosaurus* should be placed in the order Ornithischia: (1) The presence of an antorbital fenestra (usually reduced in size in later ornithischians). (2) The form of the premaxilla (deep below external nares). (3) The presence of a supraorbital. (4) The flange on the jugal. (5) The backward extension of the squamosal. (6) The presence of a predentary. (7) The presence of a coronoid process. (8) The position of the maxillary teeth (medial to the lateral surface of the maxilla). (9) The curvature of the crowns of the cheek teeth (in anterior view, convex in the upper jaw and concave in the lower). (10) The presence of enamel on only one side of the crowns of the mandibular teeth. (11) The iguanodontid-like ridging of the crowns of the cheek teeth.

For purposes of diagnosis No. 6 is by far the most important of these.

Comparison with other ornithischians. It is obvious that the first animal with which *Heterodontosaurus* should be compared is *Geranosaurus*[1], also from the Cave Sandstone.

The latter genus, however, is very poorly known. The unique specimen consists only of a broken lower jaw (predentary and dentary) and part of the upper jaw (premaxilla and maxilla); none of the tooth crowns is preserved. Recent preparation of the type of *Geranosaurus* has confirmed the presence of a predentary in this animal. It resembles *Heterodontosaurus* in its possession of enlarged teeth ('canines') in both jaws, and in the apparent absence of replacement teeth on the medial side of the existing teeth; it differs from the new genus in lacking the large diastema in the upper jaw and in the absence of a step separating the maxillary teeth from the lateral surface of the maxilla.

Other early ornithischians (or supposed ornithischians) include *Poposaurus* from the Upper Trias of

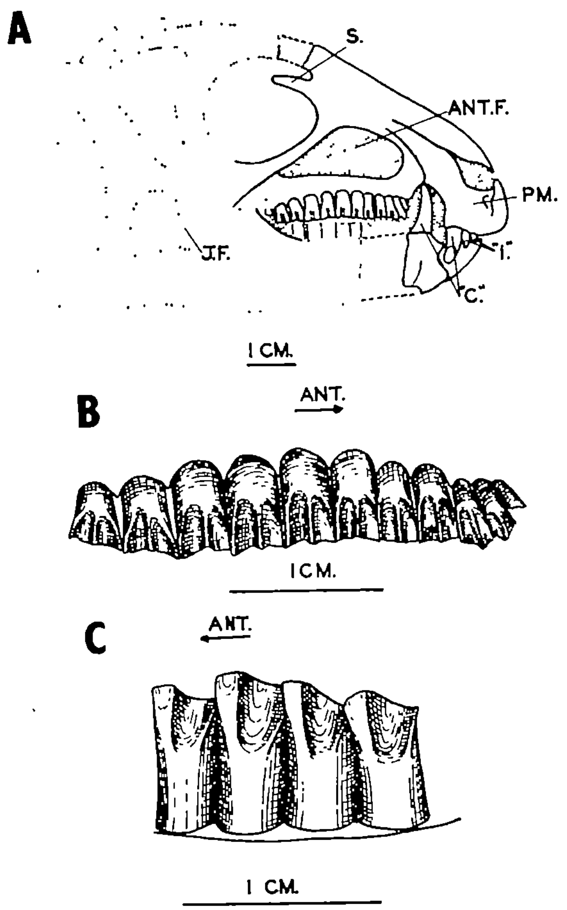

Fig. 1. *Heterodontosaurus tucki* gen. et sp. nov.
A, lateral view of the skull; *B*, lateral view of the maxillary dentition; *C*, medial view of four mandibular teeth
ANT., anterior; *ANT. F.*, antorbital fenestra; "*C.*", canines; "*I.*", incisors; *J.F.*, flange on the jugal; *PM*, premaxilla; *S.*, supraorbital

Wyoming and *Scelidosaurus* from the Lower Lias (basal Jurassic) of England. The *Poposaurus* material includes nothing of the skull; in any event, Colbert has shown[3] that *Poposaurus* is more likely to be a saurischian than an ornithischian. The only known skull of *Scelidosaurus* (in the British Museum (Natural History)) has not yet been properly prepared, but its teeth are patently quite unlike those of *Heterodontosaurus*.

Although chronologically younger than the Iguanodontidae, the Hypsilophodontidae are considered to be the most primitive family of the Ornithopoda. They include *Hypsilophodon*[4,5] from the Lower Cretaceous and *Thescelosaurus*[6] from the Upper Cretaceous. It is unfortunate that no skull of any hypsilophodontid is well known. These animals are more advanced than *Heterodontosaurus* in the smaller size of their antorbital fenestra and in certain features of their dentition: namely, in the presence of a well-developed cingulum, of more numerous vertical striations on the outer surface of the upper teeth and the inner surface of the lower teeth, and of replacement teeth medial to the lower teeth above the alveolar border. Against this, however, the hypsilophodontid dentition retains several primitive characters: *Hypsilophodon* still has five teeth in the premaxilla, the last premaxillary tooth does not appear to be enlarged, the teeth of both *Hypsilophodon* and *Thescelosaurus* are leaf-shaped, they are less elongated and less tightly packed together than in *Heterodontosaurus* (or the Iguanodontidae), and in *Thescelosaurus* enamel is present on both sides of the teeth in both maxilla and dentary. The heterodont nature of the teeth is far less pronounced in *Hypsilophodon* than in *Heterodontosaurus*.

The oldest ornithischian with which the new skull can be adequately compared is *Camptosaurus* from the Upper Jurassic. This genus, of which the skull is fairly well known, is a primitive member of the Iguanodontidae. It is like *Heterodontosaurus* in its possession of teeth which are curved towards those in the opposite jaw (the direction of curvature being as described above for the South African animal), which lack a cingulum, and which are enamelled on one side only. It is also true that both genera have a supraorbital bone of similar form. In certain features, however, *Camptosaurus* is more advanced than the new genus: the pre-orbital part of the skull is elongated, the antorbital fenestra is reduced in size, premaxillary teeth and the lower 'canine' are completely absent, the enamelled surfaces of the teeth bear many more vertical striations than are to be seen on the teeth of *Heterodontosaurus*, and there are replacement teeth on the medial side of the functional teeth. On the other hand, the teeth of *Camptosaurus* are in some respects less specialized, for they are still leaf-shaped, with relatively much lower crowns. Moreover, they were frequently replaced, so that they are not all of equal length; and this, together with the fact that they are not placed so closely together, means that they do not form a single continuous cutting edge like that of the maxillary teeth of *Heterodontosaurus*. The tooth-structure of the South African animal is altogether closer to that found in later and more specialized iguanodontids, such as *Iguanodon* itself, than to that found in *Camptosaurus*.

The Hadrosauridae of the Upper Cretaceous, though highly specialized, also show certain interesting similarities to the new genus. The individual teeth in each maxilla and each dentary are united to form a compact dental battery[7,8]. Each tooth has extremely long roots; enamel is restricted to the outer surface of the upper teeth and inner surface of the lower teeth; a single vertical ridge is present in the centre of each enamelled surface, with a shallow depression on either side; and the crowns of adjacent teeth are worn in such a way that their occlusal surfaces all lie on the same plane. In *Heterodontosaurus* the teeth do not form batteries, but all the other characters just mentioned are present and suggest a relationship to the Hadrosauridae. Replacement teeth are almost certainly present in the new specimen; but, as in the Pseudosuchia[7], they are probably lying medial to or below the roots of the functional teeth and would have become visible only when the latter had been lost or considerably worn.

Heterodontosaurus possesses characters present in each of three families of the Ornithopoda, to which sub-order it might be referred provisionally. It is clear, however, that the new genus cannot be considered ancestral to all three families. This seems to show that the main radiation of the Ornithopoda had taken place before Upper Triassic times. When the rest of the skull and the post-cranial remains of the new specimen have been prepared it may be possible to determine its relationships more certainly.

Haughton[9] gave a detailed description of the mandibular dentition of *Lycorhinus angustidens*. This animal had always been regarded as a therapsid

College, London, brought to our notice the close similarity of the dentitions of *Lycorhinus* and *Heterodontosaurus*, which appears to indicate that *Lycorhinus* was probably an ornithischian dinosaur rather than a therapsid. The mandibular teeth behind the canine' differ from those of *Heterodontosaurus*, however, in possessing a distinct cingulum. This and the nature of the wear of the teeth appear to indicate that *Heterodontosaurus* and *Lycorhinus* are generically distinct. *Lycorhinus* was found in the Red Beds; than suggested by *Heterodontosaurus*.

FLOWERING RESPONSE OF RICE TO DIFFERENT PHOTOPERIODS OF UNIFORM DAILY AMOUNTS OF LIGHT RADIATION

By E. H. ROBERTS and A. J. CARPENTER

West African Rice Research Station, Rokupr, Sierra Leone

IN the recent literature on rice there has been some discussion as to the shape of the photoperiodic response curves (duration to flowering plotted against photoperiod).

One of the first to stress the importance of constructing these curves was Chandraratna[1], who calculated that the shortest duration to flowering was obtained in photoperiods varying from 9½ to 11 h according to variety: the photoperiod which gave the shortest duration was defined as the optimum photoperiod. Chandraratna found that over a limited range of photoperiods (usually part of the range of 8–13 h), which he felt included the main range of interest to agronomists and breeders, second degree polynomials could be fitted to the data. However, since his treatments in short photoperiods received considerably less light than those in long photoperiods, this interpretation was open to question.

Njoku[2] used a technique whereby all treatments received the same amount of daylight (though not total light), the differences in photoperiod all being obtained by additional periods of low-intensity incandescent illumination. He found no evidence of an increase in duration at photoperiods shorter than Chandraratna's optima, but he did not use photoperiods of less than 9 h.

The most comprehensive series of experiments and discussion of this problem, together with a summary of the earlier work, has recently been published by Best[3], who confirms the existence of an optimum photoperiod, which varies from 9 to 12½ h according to variety; but he also convincingly demonstrates, particularly when a correction for 'non-photoperiodic effects' is applied, that the data cannot be fitted to a simple equation, even over a relatively narrow range of photoperiods. Best used an ingenious correction to allow for those 'non-photoperiodic effects', which were due to the fact that the plants in very short photoperiods received less light than those in the long photoperiods. Long photoperiodic treatments were repeated using different ratios of the period of daylight to low-intensity supplementary illumination and it was found that in any given photoperiod there was a delay in flowering in the treatments receiving less light. Points of similar duration on the sub-optimal side of the curve to those on the supra-optimal side were chosen: the duration values found on the sub-optimal side were then decreased by the same amount as the difference found between high-light and low-light results of the corresponding supra-optimal photoperiod where the low-light treatment had the same daylight period as the sub-optimal photoperiod.

Undoubtedly this method does provide an approximate solution to the problem of constructing photoperiodic response curves for high-light intensities; but it suffers from the criticism that it assumes that the interaction between light intensity and photoperiod which the results demonstrate in supra-optimal photoperiods is the same as between light intensity and sub-optimal photoperiods causing similar duration. As Best points out, " . . . [the

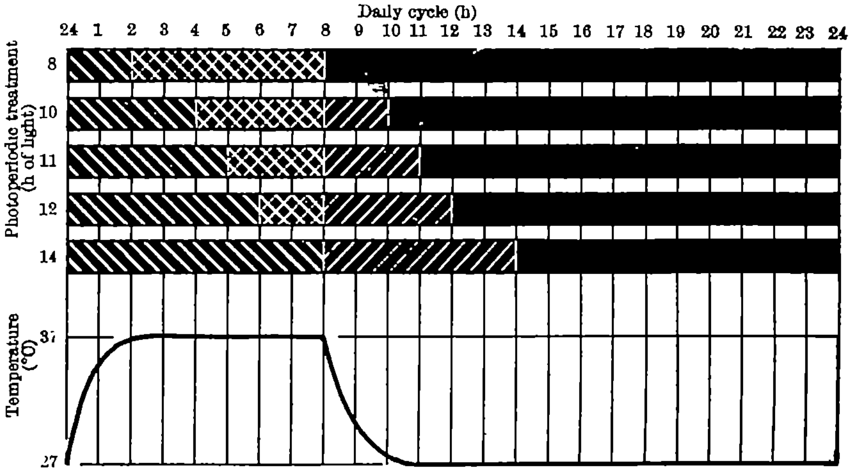

Fig. 1. Diagram showing the five photoperiodic treatments. Except for occasional minor aberrations, the temperature régime was the same (± 1·5° C) in all treatments and is shown by the graph.

method] is based on the comparison of sub- and supra-optimal photoperiods, in which the photoperiodic effect may be of a different nature".

In the experiment reported here we have attempted to eliminate non-photoperiodic effects by sacrificing high-light intensities and growing plants in controlled environments using photoperiodic treatments which provide the same total daily amounts of light. A full description of the growth chambers which were used will be published elsewhere; but the main details which apply to the present experiment are as follows. Main lighting in each chamber was supplied by eight 5-ft. 'white', 80-W, fluorescent tubes with internal reflectors which provided a light intensity of about 9,000 lux (falling to 7,000 lux at the extreme corners of the chamber) at the level of the top of the plants, which were kept about 30 cm from the light source throughout the experiment. Supplementary lighting was provided in each cabinet by four 25-W incandescent lamps which gave a light intensity between 200 and 500 lux depending on the position in the cabinet. (Wormer[4] carried out experiments on rice which indicated that maximum response to photoperiod is obtained with supplementary light at an intensity of about 40 lux and little or no effect is obtained by increasing the intensity above this value.) The same temperature régime was given in each cabinet and is shown together with the five photoperiodic treatments in Fig. 1.

Three pure-line swamp varieties were used: Radin China 4 (from Malaya), Lead 35 (a selection made at this station out of material from British Guiana), and Tai Chu 65 (from Formosa); the first two are members of the *indica* sub-species and the last is said variously to belong to the *japonica*, sub-*japonica* or *indo-japonica* group.

The seeds were first germinated for a week at 32° C in the dark, then single seedlings were transferred to 10-l. undrained polythene buckets containing mud and grown at ambient temperature in daylight for a further week. Five buckets of each variety were then placed in each photoperiodic treatment in the growth cabinets. (Best[3] found that no variety he investigated became sensitive to photoperiod until it was at least two weeks old.) A few plants died and the final replication numbers are shown in Table 1.

The results are shown in Fig. 2 and Table 1. It will be seen that Tai Chu 65 is the least sensitive to photoperiod in this experiment but even with this variety, which has the reputation of being completely insensitive, a delay in flowering occurred under a 14-h photoperiod. In the case of the other two varieties minimum duration occurred in the 10-h photoperiod; it will also be seen (Table 1) that it was at this photoperiod that least plant-to-plant variation occurred. This result can be related to an observation of agronomic importance based on the results of field successional sowing experiments made at this station[5]: when a photoperiod-sensitive crop is sown out of season so that flowering is delayed by long days, there tends to be an increase in the variability of flowering. Another interesting comparison between the present results obtained from plants grown in controlled environments and those grown in the field is the relative durations of Radin China 4 and Lead 35. The records for field successional sowing experiments[6] for five sites in West Africa (including Sapu 13° 29′ N. in Gambia and Nungua 5° 40′ N. in Ghana) show that, for any given sowing date, Lead 35 always flowers before Radin China 4. It will be seen that in every treatment where these varieties flowered in the cabinets the reverse is true. This comparison of results demonstrates that some other factor—which in this case may well be temperature—also affects duration and that considerable inter-varietal differences in response to this factor must exist, as well as to photoperiod.

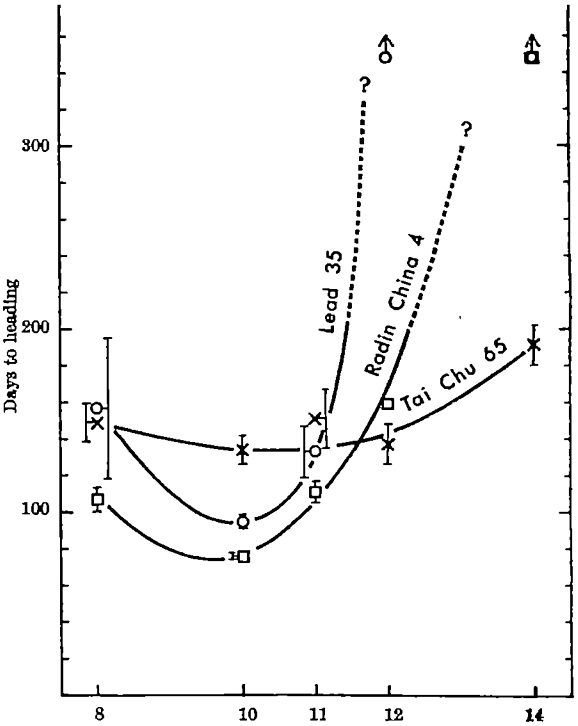

Fig. 2. Photoperiodic response curves for the rice varieties Tai Chu 65 (×), Lead 35 (○), and Radin China 4 (□). The vertical lines represent twice the *S.E.* The experiment lasted 348 days; treatments in which no flowering had occurred by this time are shown by a point at this value with an arrow pointing upwards; this symbol has also been used in the case of Lead 35 in the 12-h photoperiod where one plant out of five flowered before this time (after 215 days). Plants which were still vegetative at the end of the experiment flowered within 32 days on transfer to a 10½-h photoperiod

LETTERS TO THE EDITOR

RADIOPHYSICS

Spectrum of the Galactic Radio Emission between 10 Mc/s and 1·5 Mc/s

As part of a general investigation of cosmic radio noise at frequencies less than 10 Mc/s the intensity of the radiation has been measured at 9·8 Mc/s, 4·8 Mc/s, 2·3 Mc/s and 1·5 Mc/s. The observations were made at Hobart during July and August in 1961 and 1962. Similar arrays of three full-wave dipoles were used at each frequency, directed to declination −42°. The bandwidth of the receivers was 4 kc/s and a combination of frequency sweeping and minimum recording was used to reduce interference from transmitting stations and atmospherics. The receivers were calibrated with noise generators.

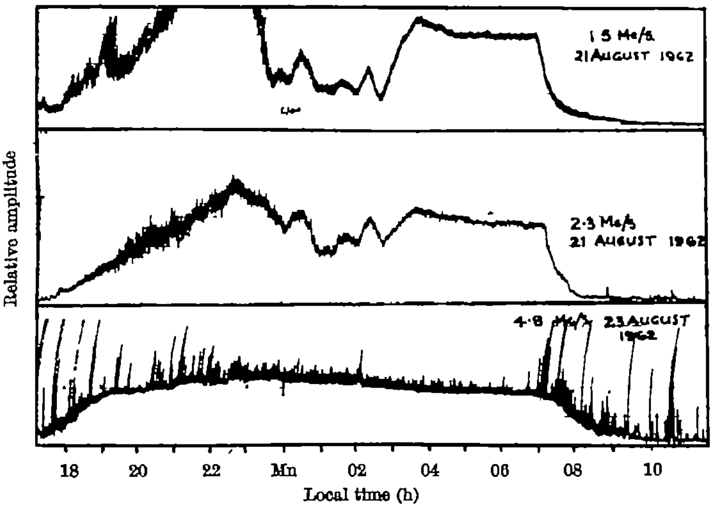

Fig. 1. Sample records of cosmic radio noise at 1·5 Mc/s, 2·3 Mc/s and 4·8 Mc/s. The first two records illustrate the effects of transmitter interference from 1900 to 2400 h and ionospheric modulation from 2400 h to 0300 h. The galactic profile appears from 0400 h to 0700 h

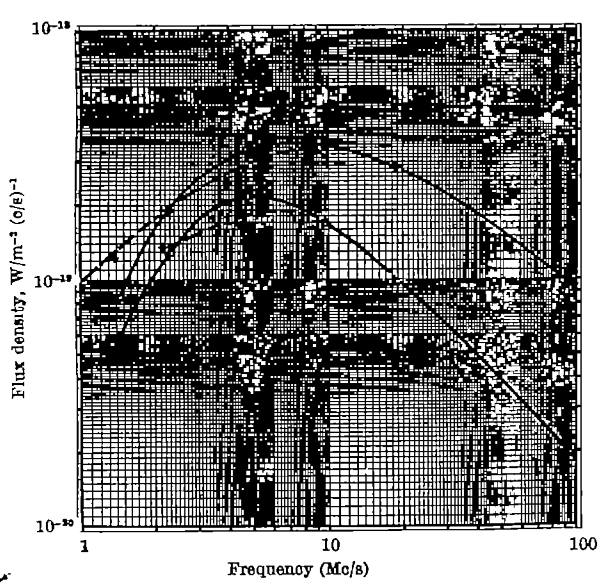

Fig. 2. Cosmic noise spectra less than 100 Mc/s. The 1956 spectra are shown dotted. Points above 10 Mc/s from ref. 2. Present observations indicated thus ○

Fig. 1 shows samples of the records at 4·8 Mc/s, 2·3 Mc/s and 1·5 Mc/s. Only records for which ionospheric modulation of the radiation appeared to be absent were used in calculating the intensities. The ionospheric critical penetration frequency, foF_2, was on a number of occasions less than 1 Mc/s and many records were obtained which reproduced the galactic sidereal profile.

Fig. 2 shows the spectra of the maximum and minimum galactic intensities. observed near 1900 R.A. and 0400 R.A., respectively. The spectrum of the maximum at frequencies less than 10 Mc/s should be interpreted with caution since high-resolution studies at 4·8 Mc/s (to be reported elsewhere) have shown much fine detail near the plane of the Milky Way. This spectrum represents an average over bright and dark regions. The spectrum of the minimum. on the other hand, is not affected significantly by spatial averaging.

Also shown in Fig. 2 are the corresponding spectra obtained in 1956[1]. It may be seen that the present spectra agree well between 2 Mc/s and 10 Mc/s. However, it now appears that the intensity decreases more below 2 Mc/s than was previously thought. In particular the 900 kc/s intensity was obtained in 1956 under rather unusual ionospheric conditions and may have to be revised in a downward direction when further results become available. It should be noted that the spectral maximum occurs at a higher frequency near the plane of the galaxy than at high galactic latitudes. In addition, at frequencies less than the spectral maximum, the intensity varies very nearly as the square of the frequency. Both of these effects may be explained in terms of absorption of the radiation in interstellar ionized gas. Their theoretical implications are discussed elsewhere[3].

METEOROLOGY

Noctilucent Clouds in Alaska during 1962

Since the first reported sightings of noctilucent clouds in 1885, there have been many subsequent observations of them from latitudes ranging between 45° and 63·3°. The majority of these observations have been made from north-western Europe and the U.S.S.R. There appear to be only three previously reported observations of noctilucent clouds from the North American continent: two of these from Canada and one from Alaska. Vestine's observation[1] of the clouds from Meanook, Alberta (54° 37′ N., 113° 20′ W.), on July 20–21, 1933, was the first reported sighting from North America. The second reported sighting from Canada[2] was made on the night of July 23–24, 1961, from Saskatoon, Saskatchewan (52° 08′ N., 106° 38′ W.). The one reported Alaskan sighting[3] was made from Anchorage (61° 10′ N., 149° 59′ W.) on July 27–28, 1957. The lack of noctilucent cloud observations at latitudes higher than 63·3° (the latitude of Torsta, Sweden) was attributed by Ludlam[4] to the lack of keen observers at these latitudes.

Following a suggestion by Prof. Sydney Chapman, a watch for noctilucent clouds was kept this summer here (64° 53′ N., 148° 03′ W.) to determine whether the clouds could be seen at higher latitudes than previously observed. On the night of August 13–14, 1962, a noctilucent cloud display was observed from College by four independent observers The clouds were first seen at approximately 2330 A.S.T. (Alaskan Standard Time, 150° W. Meridian Time) on August 13, and were observed until 0030 A.S.T. on August 14. The display, exhibiting the characteristic billow structure, was most intense shortly after midnight at which time the clouds extended in elevation up to 11° with the azimuthal extent of the clouds being approximately 25° west to 25° east of true north. A photograph of the display seen on that night is shown in Fig. 1. This picture was taken by Mr. Yngvar Gotaas on Kodochrome film at an exposure of 90 sec at *f* 5·6. Two subsequent noctilucent cloud displays, faintly visible through the cloud cover, were seen and photographed from College, Alaska, on the nights of August 14–15 and August 16–17. The display on August 14–15 was also observed at Ft. Yukon[5] (66° 34′ N., 145° 18′ W.), and the display on August 16–17 was seen from Galena[6] (64° 46′ N., 156° 54′ W.).

Noctilucent cloud displays were also observed by the Weather Bureau personnel at Anchorage on two occasions this year[7]. Their first sighting was on May 6–7, 1962, 0005–0050 A.S.T. This display was visible up to 7° above the horizon. At the beginning of the display the azimuth extent of the clouds was 303°–009°, and toward the end of the display the azimuthal extent of the clouds was 021°–071°. Their second sighting was on the night of August 11–12, 1962. This display was first seen at approximately 2300 A.S.T. and lasted until 0115 A.S.T. The elevation angle of the upper border of the display was about 10°, and the clouds extended from north-north-west to north-north-east, approximately. According to Mr. John Gardey[7] of the Anchorage Weather Bureau, the clouds are seen at least once every year from Anchorage.

PHYSICS

Bath-Tub Vortex

Perennially one hears controversy regarding the direction of the vortex in the drain of the bath-tub or the kitchen sink. Some claim that the direction of swirl is always the same in the northern hemisphere, and that in the southern hemisphere it is always opposite to that for the northern hemisphere. Others claim that there is no unique direction of swirl in either hemisphere.

Both schools of thought are in some sense correct. For the everyday observations of the kitchen sink and bath-tub variety, the direction of the vortex seems to vary in an unpredictable manner with the date, the time of day, and the particular household or experimenter. But under well-controlled conditions of experimentation, the observer looking downward at a drain in the northern hemisphere will always see a counter-clockwise vortex, while one in the southern hemisphere will always see a clockwise vortex.

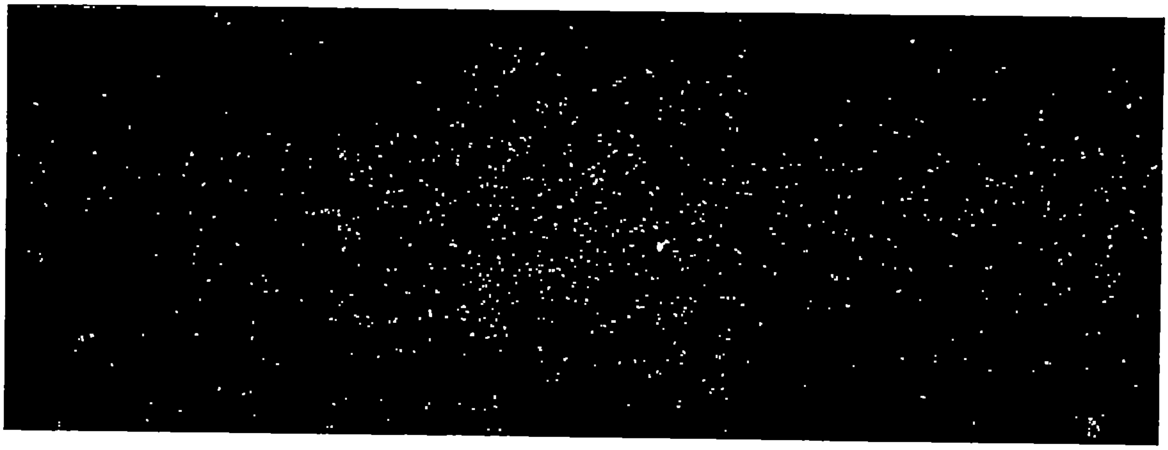

Fig. 1. Photograph of noctilucent clouds taken from College, Alaska, at 00 : 06 : 30 A.S.T. on August 14, 1962

In a properly designed experiment, the vortex is produced by Coriolis forces, which are counter-clockwise in the northern hemisphere and clockwise in the southern hemisphere.

There are two reasons for the apparent haphazard results of the everyday observations. The effective rim speed of a tank 2 ft. in diameter rotating with the Earth at Boston, Massachusetts, is only about 0·04 in./min. This tiny Earth-induced motion may be much less than other motions too small to be perceived by ordinary observation. Unless the water in the vessel is allowed to settle for many hours, for example, the residual motions from the filling of the vessel may far exceed the foregoing figure. Moreover, the very act of pulling the plug from the bottom of the vessel may inadvertently create substantial velocities. Even if many hours are allowed for settling, air currents in the room or thermal currents associated with non-uniform temperatures around the vessel may easily cause water velocities larger than that due to the Earth's rotation. All these difficulties are quite real; this was amply proved by early experiments with the apparatus described later.

The second source of confusion in the casual everyday observations is that the Coriolis forces due to the Earth's rotation may in fact be much smaller than other forces normally present. For a speed of 0·1 in./sec toward the drain, the Coriolis force at latitude 42° north is about $3(10)^{-7}$ times the force of gravity. If the vessel is not perfectly symmetrical about the axis of the drain, the asymmetrical viscous forces at the side walls and at the bottom of the vessel may produce torques larger than that due to the Coriolis force; the direction of this asymmetrical torque would, of course, vary from vessel to vessel. Even the extremely small forces of surface tension at the free surface may, owing to non-uniformities in temperature or chemical impurity, lead to torques.

A meaningful experimental demonstration of 'the bath-tub vortex' must be designed to cope with the difficulties mentioned here. Such an apparatus was made and operated near Boston for an educational motion picture entitled *Vorticity*. The tank is circular, 6 ft. in diameter and 6 in. high, with a flat bottom. The drain hole, 3/8 in. in diameter, is centrally located and flush with the bottom. A length of hose some 20 ft. long leads the water from the drain to a sump. A 'vorticity float' makes the vortex visible. This is a cross made of two slivers of wood, each about 1 in. long, pinned together with a fine wire through the centre of each. The cross floats in a horizontal plane just below the surface of the water, and a small length of wire extending above the surface of the water provides the necessary floating stability.

Before starting the experiment the end of the long hose is closed with a plug. The tank is then filled nearly to the brim with water swirling clockwise. This direction is deliberately chosen to test whether sufficient time has elapsed for adequate decay of the original motion, so that one may be confident that the swirl seen in the experiment really arises from Coriolis forces rather than from initial swirl not yet sufficiently dissipated. After filling, the tank is covered with a plastic sheet to eliminate the effect of air currents, and the room is maintained at nearly uniform temperature. About 24 h are required for settling of the motion to a degree where the residual motions are unimportant compared with those due to the Earth's rotation. The plug is then pulled from the end of the long hose and the vorticity float is delicately inserted above the drain hole. About 20 min are required for the tank to drain completely. During the first 12–15 min no rotation of the float is perceptible to the eye. At about 15 min, however, the counter-clockwise rotation of the vorticity float becomes distinctly perceptible, and gradually increases. Near the end of the experiment, when the vessel is almost completely drained, the vorticity cross turns one revolution in about three or four seconds. This is about 30,000 times greater than the effective speed of rotation of the Earth at latitude 42° N. It agrees in order of magnitude with what one would calculate theoretically on the assumption that the rotation of the float is indeed due to the Coriolis forces of the Earth.

When all the precautions described were taken, the vortex was invariably in the counter-clockwise direction.

If the plug were pulled after only about 1–2 h, the vorticity cross would begin to spin clockwise within 1–2 min after the plug was pulled, and would reach a rate much greater than the rate of counter-clockwise spin for the correct experiment. This was because the angular velocity remaining from the clockwise filling action, although not readily perceptible, was nevertheless greater than that of the Earth.

In one experiment the original clockwise swirl was allowed to settle for four or five hours before pulling the plug. An unusual result was observed. During the first two-thirds of the draining period, the vorticity float turned in the clockwise direction owing to the angular momentum of the initial swirl. After having reached a large clockwise angular velocity, the float began to slow down, ultimately came to rest, and then proceeded to accelerate in the counter-clockwise direction. This may be explained as follows. The water acquires the rotational velocity of the Earth through the diffusion of a viscous shear layer, mainly from the bottom of the tank. This viscous boundary layer on the bottom, in which the water has acquired the counter-clockwise angular velocity of the Earth, grows thicker with time. Above this boundary layer the water still retains the clockwise angular velocity associated with the initial swirl. When the vorticity float sinks to the appropriate level, it tends to reverse direction.

I am prepared to provide precise particulars of my apparatus to anyone in the southern hemisphere who wishes to perform an identical experiment for the sake of convincing any remaining doubters.

Incidentally, those who claim to have seen the direction of swirl change as a ship crosses the equator are surely pressing the case too far. At the equator the Coriolis forces vanish, and it would be virtually impossible to perform a valid experiment a short distance from the equator.

Solution of Boundary Value Problems in Plane Strain

THIS method replaces direct solutions of the Airy relation by, in effect, linear combinations of solutions of this equation for the edge dislocation. So far its use has been investigated only in connexion with the stress fields of dislocations in finite bodies; it may well be that it is useful in other connexions as well.

This technique is limited to two-dimensional representation and is as follows: the finite body is replaced by an infinite one and the free surfaces by cuts (lines) in this body. The conditions that certain normal and shear stresses must vanish over the surfaces can then be satisfied by allowing the surfaces to deform. This representation is well known[1]. However, this deformation can be represented by two mutually independent arrays of infinitesimal edge dislocation on each cut, distributed in such a way that the required stresses vanish over the cuts. The conditions on these distributions may be represented by singular integral equations which can be solved in a number of cases of interest.

Once the various distributions have been found, the stresses are obtained by direct integration of the effect of all the infinitesimal dislocations invoked.

As a first exercise in its use, this method has been used to find the displacements in a free surface when an edge dislocation lies parallel to it. The stresses obtained by integration over the (two) distributions of infinitesimal dislocations are identical with those obtained by Head[2] using another method.

Strengths of Sapphire Crystals

The strength of single crystals of entirely brittle materials should depend on the presence of stress raising flaws. Internally these could be formed by static dislocation arrays, voids or inclusions of foreign material. On the surface the flaws could be formed by mechanical damage or by surface steps as suggested by Marsh[1].

Surface damage appears to be the major factor influencing the strengths of fused silica and silicate glasses, and it was felt that this factor might also exert a considerable influence on the strength of brittle crystalline materials. Indeed, Dash[2] has already observed and reported the high strength obtainable with polished and etched single crystals of silicon.

Sapphire single crystal rods about ¾ mm in diameter (obtained from the Linde Co.) were flame polished by being rotated in, and traversed slowly through, an oxy-coal gas flame. The rods were then loaded to fracture in pure bending at room temperature, the applied couple measured and the maximum stress at the rod surface calculated by simple bending theory. The material appeared to be entirely elastic and frequently shattered completely at fracture.

The techniques used in flame polishing, handling and applying the bending moment were developed for the preparation of strong silica samples of similar dimensions and will be described in detail elsewhere. The main feature of these techniques was the great care taken to prevent any damage to the flame polished surface and to this end the bending couple was applied via 'Araldite' plugs cast around the rod ends. An 'Araldite'-free test length of several millimetres was left in the centre of the rod.

Fig. 1 shows the result of the bending tests. The strengths recorded after polishing sometimes were an order of magnitude greater than those of the 'as received' rod ranging from nearly 400,000 lb./sq. in. to over 1,000,000 lb./sq. in. The higher strengths are comparable with the strengths of alumina whiskers reported recently[3].

METALLURGY

250° C Internal Friction Peak in Iron

An internal friction peak, which occurs in iron at temperatures of about 250° C and frequencies of the order of 1 c/s has been the subject of some speculation[1]. The purpose of this communication is to suggest that the cause of the peak is diffusion of oxygen in iron.

According to the most recent measurements[1,2], the activation energy of the peak is 32–35 kcal/mol. Although the activation energy of diffusion of oxygen in α-iron has not been measured directly, it can be obtained from the Cottrell equation[3] for serrated yielding in a tensile test:

$$D = 10^{-9}\,\dot{\varepsilon} \tag{1}$$

where D is the diffusivity and $\dot{\varepsilon}$ is the strain-rate. Equation (1) has been verified for a number of body-centred-cubic metals[4]. Boulanger[5] has found serrated yielding in iron at a strain-rate of 6×10^{-3} sec^{-1} and a temperature of 325° C. Therefore:

$$D_0 \exp[-\Delta H/RT] = 6 \times 10^{-12} \tag{2}$$

For diffusion of interstitial atoms in body-centred-cubic metals, D_0 is typically 10^{-2} cm^2/sec (ref. 6); and ΔH, the activation energy for diffusion of oxygen, becomes 28 kcal/mol. Considering that Boulanger[5] reported the lowest temperature at which serrations appeared and not the temperature of the maximum effect, the value of 28 kcal/mol represents a lower limit on the activation energy for diffusion of oxygen in iron, and the agreement between this value and the activation energy of the internal friction peak is good. Therefore, it seems likely that the internal friction peak is caused by diffusion of oxygen.

CERAMICS

Influence of Surface Area on the Density of Quartz heated at 1,300°–1,500° C

During an investigation of silica brick it soon became apparent that the extent of the thermal alteration of quartz was dependent on its initial particle size. A search of the literature revealed only a few fragmentary pieces of information[1–5]. Most of this information merely compared the extent of alteration of two fractions, a fine and a coarse, and stated that the finer fraction is altered to the greatest extent. The finer fraction was coarse compared with the quartz used here. Therefore a systematic, qualitative investigation of the influence of the initial surface area of quartz on the extent of its thermal alteration, as measured by density changes and X-ray diffraction, was undertaken. The purpose of this communication is to emphasize graphically the extent of this surface area effect.

For this work, well-crystallized α-quartz samples were obtained from Illinois and Pennsylvania producers. Spectrographic analysis indicated that the upper limits for lithium, molybdenum, sodium, barium and manganese were 0·001 per cent; for titanium, magnesium, calcium, iron and potassium, 0·01 per cent; and for aluminium 0·1 per cent. The surface area of each fraction was measured by the Brunauer–Emmett–Teller nitrogen adsorption method. 4-g samples of each fraction were heated in a platinum boat in a tube furnace in a current of water-saturated air (saturation temperature 30° C) flowing at 0·10 ft.^{3}/min. The samples were inserted into the furnace and removed while it was maintained at the selected testing temperature. Exposure times for each fraction ranged from 0·5 to 15 h. Density determinations were made at 35° C by the pycnometer method with *m*-xylene as the displacement liquid. Duplicate determinations agreed to ± 0·005 g/cm^3.

Figs. 1 and 2 clearly show that, for equal heat treatments, quartz samples of larger initial surface area exhibited lower densities. From X-ray diffractometer counting measurements an increase in cristobalite and decrease in quartz content was always observed when the density decreased. When the density of cristobalite (2·33 g/cm^3) was neared, no quartz could be detected. At temperatures above 1,400° C the surface effect tapers off above 1–2 m^2/g. However, at the lower temperatures the surface influence increases up to at least 5 m^2/g.

No tridymite formation was detected in any sample. The observed absence of tridymite in heat-treated, high-purity silica agrees with the findings of others[6-8].

Chaklader and Roberts[4] and Roberts[3] point out that the quartz transformation occurs as consecutive reactions: quartz→transition phase (amorphous)→ cristobalite. They found considerable amounts of the transition phase in their heat-treated quartz samples, since the rate of its formation was greater than that of its disappearance. Mackenzie[5] observed that the direct solid–solid transformation of quartz to cristobalite was equally possible.

If the rate of formation of the transition phase is greater than its disappearance, as Roberts has shown, then the decrease in density observed in Figs. 1 and 2 is due to the formation of cristobalite and transition phase mixtures. However, if the rates of appearance and disappearance are equal, as Mackenzie suggests, then the change in density is due to the formation of cristobalite alone. Regardless of the mechanism, density values still indicate the relative influence of surface area on the extent of thermal alteration. This is true since the density of cristobalite (2·33 g/cm^3) and the transition phase (2·30 g/cm^3)[3] are of the same magnitude, and a mixture of these two would have a density very nearly that of cristobalite alone.

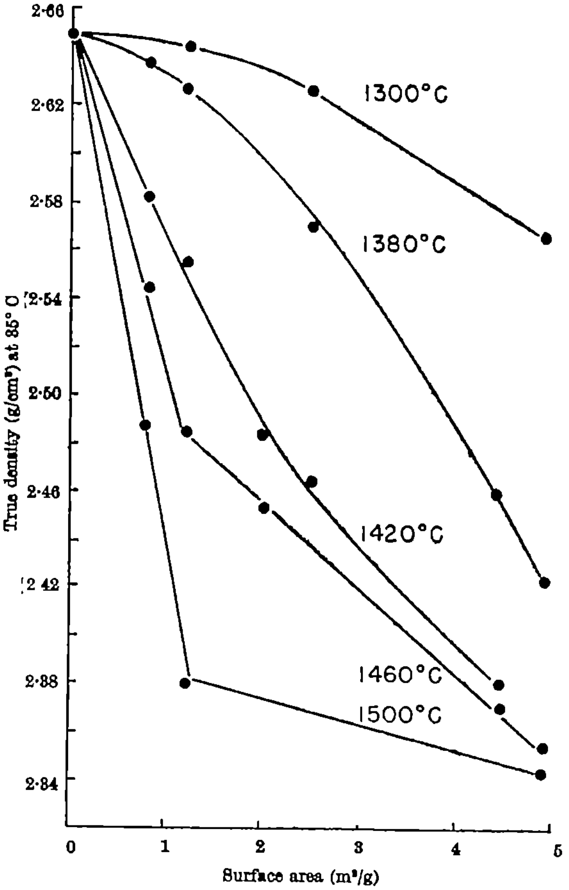

Fig. 1. Influence of the initial surface area of quartz on the true density after 2 h at the indicated temperatures

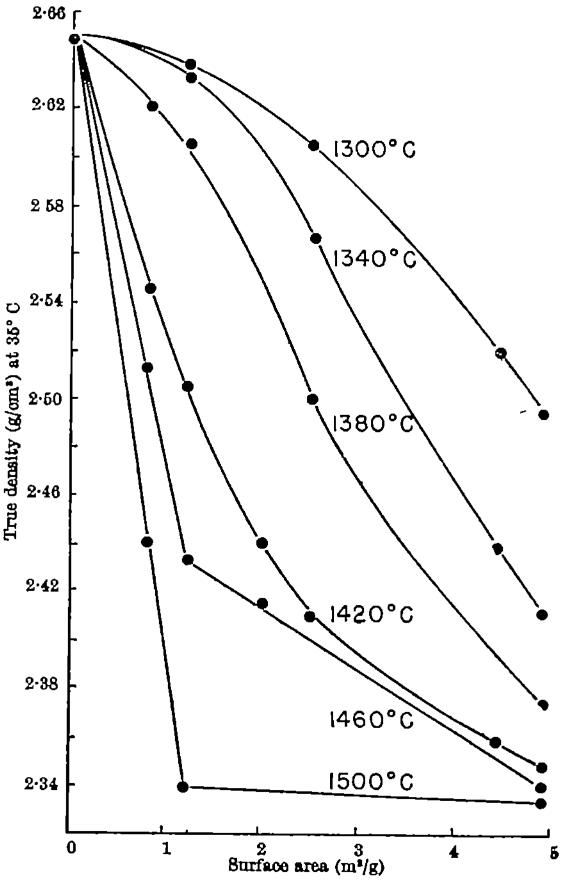

Fig. 2. Influence of the initial surface area of quartz on the true density after 4 h at the indicated temperatures

Furthermore, Roberts[3] states that for finely divided quartz the growth and subsequent decay of the transition phase becomes almost identical. It is possible to conclude from this statement that both mechanisms may prevail: direct conversion for high surface samples and indirect for samples of lower surface.

The major impurity in the quartz used here is aluminium. This probably comes from clay impurities. Grimshaw *et al.*[2] have shown that the presence of 0·7 per cent of Al_2O_3 greatly retards the transformation. Therefore, the Al_2O_3 in our samples, although in a much smaller concentration and chemically combined with silica, may slightly influence the results, but in no way negate them.

This work was carried out while I was associate chemist, Illinois State Geological Survey, Urbana.

that “much of the so-called greywacke of the Siwaliks may, in fact, turn out to be sub-greywacke (the low-rank greywacke of Krynine) if a proper petrographic study is made. If this is the case [they say], the notion that the Siwaliks are entirely of freshwater origin may still be true, because the sub-greywackes are neither necessarily marine nor are they confined to the geotectonic belts”.

Greywacke was first described from the Siwaliks by Krynine[3], who fully accepted the palæontological evidence for a non-marine environment of deposition. The Siwalik greywackes are referred to and illustrated in Pettijohn's well-known text-book[4]. The idea, now commonly held, that greywackes are restricted to a marine environment in the orogenic belts is of quite recent origin; it is founded on hypothesis, and is contrary to observation. Examples of non-marine greywackes are to be found in the Old Red Sandstone of Lanarkshire, Scotland[5], the Pennsylvanian of Rhode Island and Massachusetts[6], and in the Eocene of Wyoming[7].

Sedimentary and tectonic environments are only two among many factors which affect the petrography (texture and composition) of sandstones. Klein[8] has recently emphasized the importance of provenance and Dapples[9] has stressed the possible effects of diagenesis. There is much evidence to suggest that greywacke (sandstone with a ‘muddy’ matrix) results from the post-depositional alteration of ‘normal’ (clean or mud-free) sand of suitable initial composition[10].

The sandstones of the Siwalik Series are characterized by a large content (35–40 per cent) of schist and phyllite fragments, and vary little in composition through a thickness of 20,000 ft. of strata. Among these sandstones, greywackes are in the minority and are only recorded from the lowest division of the Siwalik Series[3]. The inference is that all the Siwalik sandstones were deposited as ‘normal’ sands and some of the oldest of them were converted by pressure and temperature, resulting from deep burial, to greywackes[10].

The mere presence of greywacke cannot be accepted as evidence of marine sedimentation. Petrography, as a guide to depositional environment, is very much inferior to the careful use of fossils and sedimentary structures.

The experimental techniques used in this investigation have been described elsewhere[2,3]. The accuracy and precision of the method were determined by periodic analyses of an interlaboratory strontium standard. The results of these analyses agreed closely with those reported by others, giving confidence in the accuracy of the technique. The reproducibility of measurement of the ^{87}Sr/^{86}Sr ratio was calculated from 18 analyses of the standard to equal ± 0·0015 (0·2 per cent). The measured ^{87}Sr/^{86}Sr ratios were normalized to ^{86}Sr/^{88}Sr = 0·1194 as described by other workers[2].

In order to interpret the data it was first necessary to learn something about the effect of diffusion of strontium-87 on the ^{87}Sr/^{86}Sr ratios of carbonate xenoliths. A completely recrystallized xenolith of Trenton limestone at Mt. Royal, Quebec, about 18 × 24 in. in size, was used for this purpose. X-ray fluorescence analyses revealed that the xenolith contained approximately one-half as much strontium as the igneous rock surrounding it. ^{87}Sr/^{86}Sr ratios were measured in the xenolith, in the igneous rock, and in a sample of unaltered Trenton limestone. The xenolith was found by a duplicate analysis to have preserved the ^{87}Sr/^{86}Sr ratio of the Trenton limestone, 0·712, even though surrounded by a relatively strontium-rich magma with a ^{87}Sr/^{86}Sr ratio of approximately 0·708. Since measurable diffusion of strontium-87 did not occur in a xenolith of this small size it seems very improbable that it could have been effective in bodies of carbonate rock the size of most carbonatites.

^{87}Sr/^{86}Sr ratios were measured in both carbonatites and alkaline rocks from the complexes at Oka, Quebec; Magnet Cove, Arkansas; Iron Hill, Colorado; and Rocky Bay, Montana. An example of the results of these analyses is given in Table 1.

An average ^{87}Sr/^{86}Sr ratio for Grenville carbonates and celestites was calculated from the available data[1,2–5]. The results are given in Table 1. The Oka carbonatite has been considered to be a xenolith of Grenville marble by some authors[6,7]. The results in Table 1 show that the ^{87}Sr/^{86}Sr ratio of the Oka carbonatite is identical within the analytical precision to those of the alkaline rocks of the complex and is distinctly different from those of the Grenville rocks. This indicates that the Oka carbonatite is not a xenolith of Grenville marble but rather that it is comagmatic with the igneous rocks of the complex. Additional evidence to support this conclusion is found in the fact that a rubidium–strontium age determination on a biotite from the Oka carbonatite yielded a Mon-

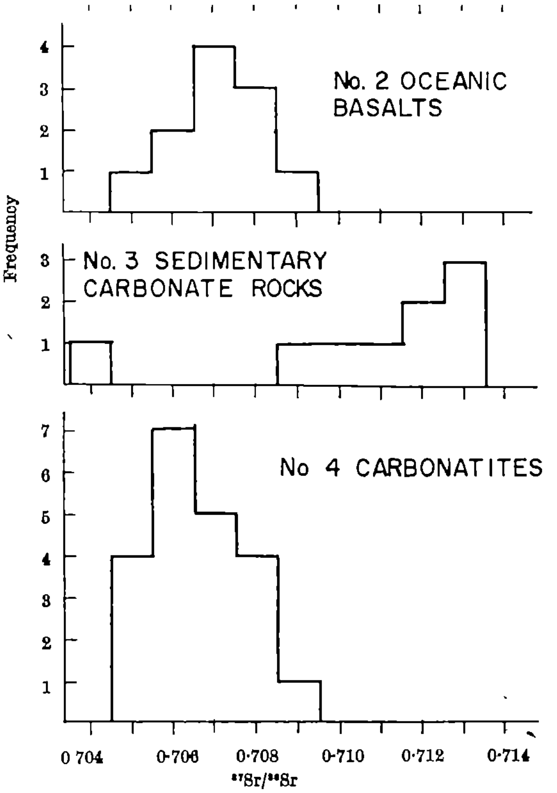

Fig. 1. Frequency distribution of ^{87}Sr/^{86}Sr ratios in various rock types

teregian age of 100 million years rather than a Grenville age of around 1 billion years[3]. The ^{87}Sr/^{86}Sr ratios of the carbonatites in the other complexes which were examined were also found to be identical within the analytical precision to those of the associated alkaline rocks.

Duplicate ^{87}Sr/^{86}Sr ratio determinations were carried out on the Spitzkop carbonatite and on the Transvaal dolomite from which this carbonatite is supposed to have been derived[8]. The ^{87}Sr/^{86}Sr ratio of the carbonatite was found to equal 0·7058 ± 0·0010 and that of the dolomite 0·7129 ± 0·0010. This evidence confirms the conclusion of other writers[9,10] that the Spitzkop carbonatite is not a mobilized xenolith of Transvaal dolomite.

^{87}Sr/^{86}Sr ratios were measured in a total of 21 carbonatites. The results of these analyses are compared in Fig. 1 with the data reported by Faure and Hurley[2] for basalts and with the data available for sedimentary carbonate rocks[1,3-5]. The mean ^{87}Sr/^{86}Sr ratio of the carbonatites was calculated to equal 0·7065 ± 0·0003.

The available experimental evidence indicates that migration of strontium-87 in carbonate xenoliths is negligible, and as shown in Fig. 1 the ^{87}Sr/^{86}Sr ratios

The spread observed in the ^{87}Sr/^{86}Sr ratios of the carbonatites is only about three times the reproducibility and is similar to the spread in the ratios of the 25 basalts measured by Faure and Hurley[2]. This appears to indicate that the source material of carbonatite is as homogeneous in its ^{87}Sr/^{86}Sr ratio as is the source material of basalt magma. In addition the ^{87}Sr/^{86}Sr ratios of the carbonatites and the associated alkaline rocks are lower than those of rocks usually found in the sial. This result supports the conclusion that the source material of these rocks is located beneath the sial.

The conclusion that carbonatites are not xenoliths of limestone does not necessarily imply that they do not contain resurgent carbon dioxide. For example, consider a magma of subsialic origin which completely dissolved a limestone and produced a carbonatite by differentiation. A carbonatite formed in this way would contain resurgent carbon dioxide, yet its ^{87}Sr/^{86}Sr ratio could be nearly the same as that of the primary magma. If carbonatites in general are formed in this way their ^{87}Sr/^{86}Sr ratios should be found to equal those of the most probable primary magma type, basalt. Yet as shown in Fig. 1 the ^{87}Sr/^{86}Sr ratios of carbonatites appear to be slightly lower than those observed in basalts. This result, if confirmed by more analyses of basaltic rocks, would indicate that carbonatites contain juvenile rather than resurgent carbon dioxide. In addition it would indicate that carbonatites are not formed by differentiation of basalt magma.

In summary, our results provide quantitative evidence which indicates that carbonatites are not xenoliths of limestone but are comagmatic with the alkaline rocks with which they are associated. The results support, but do not prove, the conclusion that carbonatites contain juvenile carbon dioxide and that they are derived from a homogeneous subsialic source which is not basalt magma.

GEOCHEMISTRY

Cyanogen Band Suppression in Direct-Current Spectrographic Analysis

THE violet cyanogen band sequences render the region 3500–4200 Å of the spectrum of little use for analysis due to excessive interference, yet sensitive lines of many elements fall within this range[1]. When carbon or graphite electrodes are used there are two methods whereby this interference may be reduced. The first makes use of the fact that band intensity is enhanced by high arc temperatures, and consequently the phenomenon of 'selective volatilization' is utilized, the plates being exposed only during the first part of the arc burn. In this period all the more volatile elements come off and the arc temperature is depressed. The procedure was described in detail by Ahrens and Taylor[2]. The second method is to prevent the emission of cyanogen bands by arcing in an inert atmosphere. The procedure described here uses this principle and is specifically designed to involve no increase in time over normal rapid spectrographic methods.

The apparatus is very simple both in design and construction. As described, it will fit the standard Hilger and Watts routine arc and spark stand *FS*.55 and the simplest modification will adapt it for use with any similar apparatus.

The modified Stallwood jet[3] used is shown in Fig. 1. All parts are of brass, heavily chromium-plated after construction. The apparatus was made here, a simple lathe being used for both jet and stand. The body *A* is made in two pieces, silver soldered together, to which the gas inlet tubes *D* are similarly attached. The latter are bent round and joined, by means of a simple T-junction, to a single tube of the same diameter some 17 cm in length. The gas mixture is supplied via a flow-meter and short length of rubber tubing from a single cylinder of pre-mixed gases: the latter is used to overcome mixing and control difficulties. The jet unit is held in position by a second horizontal tube, some 6 cm in length, attached by a vertical thread to the Petrey table mounting of the stand. The unit can slide horizontally within the mounting to allow for thermal expansion. The vertical thread is not locked in position on the mounting, hence all the controls provided by the stand unit are unimpaired. The electrode *B* is fitted with a silica collar *C*, made from standard 'Vitreosil' tubing This can be made to fit tightly, or a shoulder turned on to the electrode to allow the collar to sit in position. The unit of collar and electrode moves vertically with respect to the jet during burn, the collar being incorporated partly for insulation. Similarly the Petrey table mounting is insulated from the arc stand case.

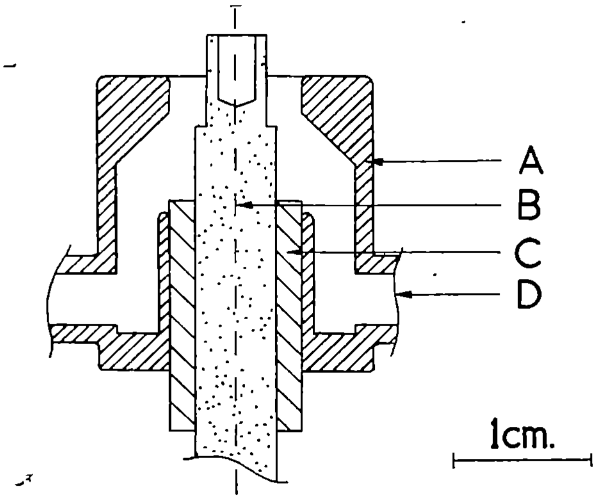

Fig. 1

Fig. 2 shows three sample spectra of identical exposure (3 min at 7·5 amp) reproduced directly from an Ilford *N*.30 plate. All are from the same powdered rock specimen containing approximately 0·1 per cent molybdenum. The region chosen is that around cyanogen band (head) 3883 Å, the most intense sequence. Case (*a*) shows the spectrum resulting from a normal arcing in air. Cases (*b*) and (*c*) are spectra produced by the apparatus described here, under different rates of gas-flow, 2 and 4 l./min respectively. Two sensitive molybdenum lines, Mo. 3,798.252 and Mo. 3,864.110, are identified for comparison.

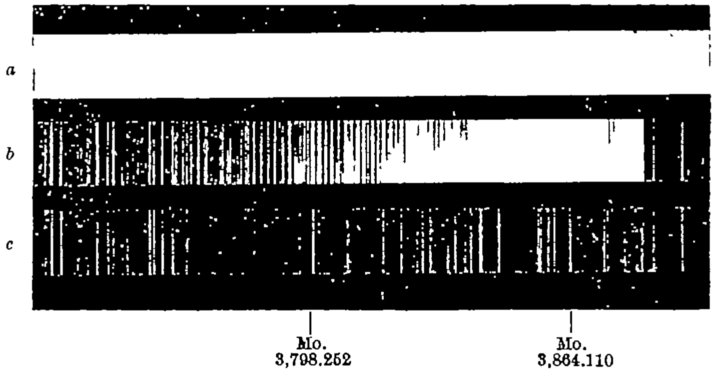

Fig. 2

The gas mixture chosen was argon/oxygen, the choice partly influenced by the cost and availability of the gases in question. By experiment a ratio of 80 per cent argon : 20 per cent oxygen was found to give line intensities strictly comparable with those in air for identical exposures. The critical flow-rate for complete cyanogen band suppression, using this mixture, was found to be 4 l./min. Annell and Helz[3] concluded that, after a comprehensive study of the properties of a direct current arc in different gases and mixtures, similar mixtures of argon and oxygen were ideal

An inert atmosphere, as well as removing cyanogen band emission from the spectrum, may possess other advantages when used in spectrochemical analysis. The work of Vallee, Reimer and Loofbarrow[4], and also Shaw, Wickremansinghe and Yip[5], indicated that the intensity of certain atom and ion lines is enhanced under these conditions with respect to air.

In their work, Shaw *et al.* also describe an apparatus developed for cyanogen band suppression using inert atmospheres. This used a partially enclosed chamber surrounding a Stallwood jet. The work included a study of the behaviour of volatile elements in an arc surrounded by an inert atmosphere, and demonstrated the value of the method in this field also. The apparatus described in the present paper was designed primarily for involatile elements analysis, where the large percentage of carbon normally mixed with the charge and the necessity for complete burn together greatly enhanced cyanogen band formation. The most important advantage of the technique described is that there is no increase in operational time, since the only departure from standard practice is the addition of silica collars after electrode preparation, just prior to arcing. The advantages of the remotely controlled, enclosed, arc stand are fully maintained. Contamination risks are slight since the jet does not come into actual contact with the electrodes, and also it may easily and quickly be removed for cleaning. The silica collars are cleaned between use by acid treatment.

RADIOCHEMISTRY

Rapid Determination of Tungsten in Steel by Neutron Activation and γ-ray Spectrometry

A NEUTRON activation analysis method has been devised for the non-destructive, rapid determination of tungsten in steel

In the present work, varying amounts (0·01–0·1 g) of a sample to be analysed are placed by turns in the nuclear reactor *JRR*-1 for 4·5 sec to be irradiated with neutrons at a flux of 3×10^{11} neutrons per cm^2/sec and then the γ-ray spectra and the decay of nuclide formed are observed by use of a 2-in. thick, well-type sodium iodide crystal attached to a 256-channel pulse-height analyser, the sample being placed at about 1 cm above the well together with its container. Typical spectrograms thus obtained are shown in Fig. 1, the shapes of which have been found to be analogous to those obtained from a standard sample (tungstic acid powder). From the successive spectra (Fig. 1, *A*–*D*) the half-life of nuclide formed can be determined to be about 5·5 sec. Tungsten is thus identified from both spectra shape and half-life. Its amount can be determined by the comparative method as usual.

From Fig. 1, which represents a sample of 2·0 per cent tungsten content, it can be deduced that one-tenth of this concentration of tungsten would produce an adequate intensity of γ-rays. Since good results are obtained when a sample taken involves about 1 mg of tungsten, the higher the tungsten concentration, the smaller the preferable amount of the sample.

The coefficient of variation of single analyses can be deduced (from a similar experiment[1] in which ytterbium was determined by use of the formation of 6-sec ^{m}Yb) to be about 5 per cent if the activity level is suitable to the analyser used and interferences are negligible.

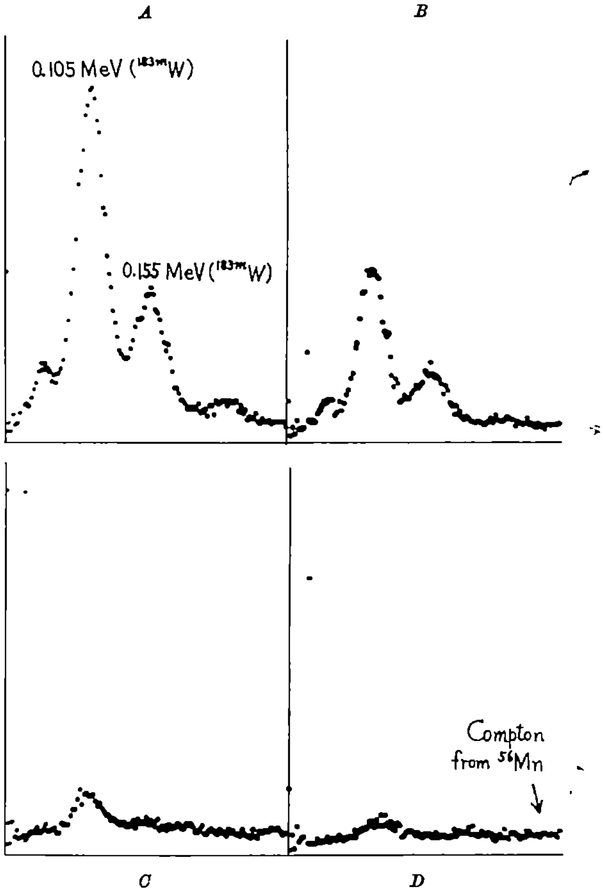

Fig. 1. Successive spectra for γ-rays of a steel sample (70·7 mg) irradiated for 4·5 sec. *A*, at 4 sec after irradiation (the pulse-height analyser was operated for 5 sec); *B*, at 10 sec (for 5 sec); *C*, at 27 sec (for 10 sec); *D*, at 47 sec (for 10 sec). The composition of this sample: Fe, 96·3; W, 2·0; C, 0·6; Mn, 0·4; Cu, 0·3; Si, 0·3; Cr, 0·12; Ni, 0·06

Possible interferences have been investigated by use of a graphical method[2] and of the effective activation cross-section of ^{182}W obtained in this work. Table 1 shows the amounts enough to interfere, at several sec after 4·5-sec irradiation, through γ-rays of nearly decuple the intensity of that from 1 mg of tungsten.

Table 1. AMOUNT REQUIRED TO EMIT γ-RAYS OF THE INTENSITY OF 10 TIMES MORE THAN THAT DUE TO 1 MG OF TUNGSTEN

Ag	1 μg	Eu	1 mg
Dy	0·01 mg	Cu	3 mg
Rh, Sc, V	0·02 mg	Ti	0·02 g
Se, In	0·03 mg	Mo	0·1 g
Er	0·1 mg	Ni	1 g
Al, Co	0·2 mg	S, Cr, Si, Fe, P, C	>1 g
Mn	0·3 mg		

I thank Prof. Shoji Makishima for advice, Dr. Fumio Aoki for his interest and Dr. Toshio Nakai, Dr. Yuichiro Kamemoto and Dr. Masao Shibuya for help with γ-ray spectrometry.

CHEMISTRY

Luminescence in Plastics

THE luminescence of organic molecules dissolved in a variety of plastics has been examined during the course of a search for new organic optical maser materials. Most plastics are compatible with organic compounds, are optically homogeneous even at liquid nitrogen temperature, have high dielectric strength, and can, of course, be fabricated in a wide variety of forms. In some cases, notably the polycarbonates, they are hard and can be fabricated to optical flatness. Of particular interest is our finding that many aromatic hydrocarbons and dyes dissolved in most plastics exhibit phosphorescence at room temperature.

The luminescent compound can be introduced into the plastic by one or another of three methods: (1) casting from a solvent for both the compound and the plastic; (2) melting a mixture of the crystalline compound with the powdered thermoplastic while pressure is being applied; (3) polymerization to solidification of a vinyl monomer in which the compound is dissolved. Thus, aromatic hydrocarbons are introduced into purified polymers including a polycarbonate (2,2-propane*bis* (4-phenyl carbonate)), polystyrene, polymethylmethacrylate, polyvinyl acetate, cellulose acetate, ethyl cellulose, and methyl cellulose. Water-soluble dyes are introduced into polyvinyl alcohols of different degrees of acetylation and into some cellulose derivatives by the solvent technique (No. 1 above). Excitation of the luminescent plastic was carried out with the 365-mμ line of a mercury lamp or with the light from a xenon-filled electronic photographic flash lamp. Phosphorescence lifetimes were determined from the decay of emission following excitation with the flash lamp. The emitted light, modulated by a rotating sector, fell on a multiplier phototube the photocurrent of which was impressed on the vertical plates of a slow-sweep oscilloscope and the trace was photographed. In some cases, the decay deviated from a single exponential curve especially in the beginning and end of the trace and hence lifetimes were calculated from the middle portion of the trace. Phosphorescence spectra were obtained with a spectrograph and densitometer tracings were made of the photographs.

Oxygen quenches the phosphorescence of the compounds in plastics. At room temperature a luminescent plastic film which had been evacuated (10^{-5} mm. mercury for 0·5 h) exhibits a progressive decrease in phosphorescence lifetime after oxygen is introduced. On re-evacuation the phosphorescence lifetime is restored and the cycle can be repeated. In certain cases, notably polyvinyl alcohol at room temperature, phosphorescence of dyes can be observed without prior evacuation[1], presumably due to the low diffusivity of oxygen in the plastic[2], although prolonged evacuation considerably increases the lifetime. We attribute the abrupt decrease in intensity of phosphorescence of the plastic in air at the transition temperature of polyvinyl alcohol in part to the marked increase of diffusivity of oxygen in the material above that temperature. Samples are prepared by pressing a molten thermoplastic between two glass plates to which it must adhere and allowed to solidify, and phosphorescence can be excited for several weeks. The diffusion of oxygen into a phosphorescent moulded plastic object can be observed visually by the movement of the phosphorescent boundary and we are at present determining diffusion coefficients of oxygen into plastics by this method. Samples which had been quenched with oxygen at room temperature nevertheless exhibit a strong phosphorescence at liquid nitrogen temperature in the presence of ambient oxygen.

A number of aromatic hydrocarbons including naphthacene, phenanthrene, chrysene, dibenz[*a,h*]-anthracene, and fluoranthene exhibit their characteristic β-phosphorescence in plastics even at room temperature. This type of phosphorescence has previously been observed at liquid nitrogen temperature in ether–isopentane–alcohol (EPA) glass. Although this type of glass is a suitable matrix for hydrocarbons it is only useful in this limited low-temperature region. Glycerol, a classic solvent for the observation of phosphorescence of dyes[4], is suitable only in the temperature-range from about −30° C to −130° C, below which it shatters. Boric acid glass is a suitable matrix for the observation of phosphorescence at room temperature; but its preparation requires the use of elevated temperatures which usually causes some decomposition of the organic solute. The glass is difficult to fabricate in a reproducible manner, crystallizes and is sensitive to moisture[5]. According to our experiences boric acid glasses have poor transmittance in the ultra-violet region due to optical inhomogeneities and to ionic impurities. Phosphorescence of dyes has been studied in glucose glasses[6]. Such glasses are very sensitive to moisture and, depending on nuances in their preparation, exhibit strong near ultra-violet absorption, presumably due to oxidation products which are readily detected by their strong electron spin resonance signal.

The lifetime of phosphorescence of the aforestated aromatic hydrocarbons depends both on the nature of the compound and on the polymeric matrix. For a given matrix, dibenzanthracene showed the longest lifetime (1·3 sec in polycarbonate). Fluoranthene is exceptional in that it shows the same lifetime (about 0·3 sec) in a wide variety of plastics at room temperature. Chrysene, on the other hand, has a lifetime ranging from 1·1 sec in polyvinyl acetate to 0·36 sec in ethyl cellulose (degree of substitution 2·5). In cellulose acetate with the same degree of substitution the lifetime of phosphorescence of chrysene is 0·70 sec. The lifetime of phosphorescence of acridine yellow in a series of substituted polyvinyl alcohols shows a decreased lifetime with increasing degree of acetylation. In all cases lowering the temperature of these degassed samples increases the lifetime. Thus the lifetime of phosphorescence of chrysene in polystyrene at liquid nitrogen temperature, namely, 2·2 sec, is three times that observed at room temperature. These results indicate that the lifetime of phosphorescence is influenced not only by the 'local viscosity'[1,7] in the plastic (micro-Brownian movement of the polymer segments) but also by specific interaction of the compound with the polymeric matrix. Thus chrysene exhibits in polyvinyl acetate, the softest plastic at room temperature which we examined, a longer lifetime (1·1 sec) than that exhibited for other plastics.

Since diffusional bimolecular processes are suppressed in plastics they provide a convenient matrix for the entrapment of metastable species at room temperature including those produced photochemically. For example, irradiating 2-methyl anthraquinone in cellulose acetate (degree of substitution 2·44) with near ultra-violet light yields stabilized luminescent intermediates the absorption spectra of which are close to those found by flash photolysis[8] of solutions in ordinary fluids where the intermediates usually have short lifetimes. Pyrene in fluid media forms an unstable photodimer and the process is believed to be diffusion-controlled[9]. We observed the same phenomenon in polycarbonate the local viscosity of which must be several orders of magnitude greater than ordinary liquids, thus excluding, at least for this medium, the notion of a diffusion-controlled mechanism for formation of the photo-dimer. Benzophenone-sensitized phosphorescence of naphthalene was first demonstrated in EPA glass at liquid nitrogen temperature[10]. We observed this energy transfer process in polymethylmethacrylate at room temperature.

A detailed investigation of the phosphorescence of organic compounds in plastics should help in better understanding the origin of emission processes from excited species. The possibility of varying the temperature over a wide range without losing the rigidity of the matrix seems to be very attractive. Thus one can examine the effect of populating higher vibrational levels on energy transfer processes involving metastable excited states.

Perturbations of such excited species by variation in the nature of the medium can also be examined. Furthermore, the studies of phosphorescence in plastics can give new information about the microscopic rheology of the polymeric matrix itself. Thus the measurement of depolarization of phosphorescence should prove useful with regard to slow relaxation processes in plastics.

Tensile Behaviour of Pyrolytic Boron Nitride to 2,200° C

BORON nitride is sometimes referred to as 'inorganic graphite' because its structure is like graphite with alternating boron and nitrogen atoms replacing the carbon atoms in the hexagonal structure. Its sublimation temperature (3,000° C) is somewhat lower than that of graphite. Boron nitride has been reported to have a greater oxidation resistance than graphite and is therefore of interest for some high-temperature applications.

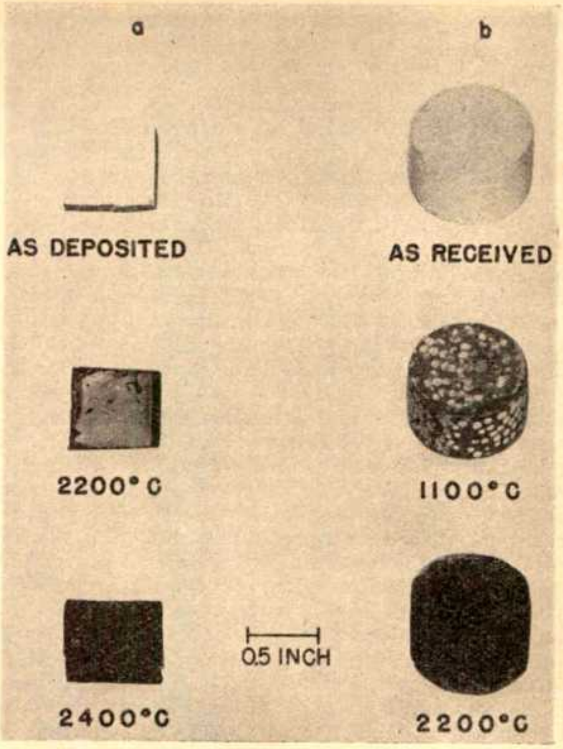

Fig. 1. Appearance of specimens after 30 min at various temperatures. *a*, Pyrolytic boron nitride; *b*, hot-pressed boron nitride

During the past months techniques have been developed for producing massive pieces of boron nitride by a pyrolytic process similar to that used to produce pyrolytic graphite. It had been hoped that the boron nitride thus produced would show an improvement in mechanical properties over the hot-pressed material similar to the improvement in pyrolytic graphite properties over pitch-coke graphite. Tensile properties of pyrolytic boron nitride parallel to the substrate direction have been measured from room temperature to 2,200° C and have been compared with hot-pressed boron nitride and with pyrolytic graphite.

The pyrolytic boron nitride tested was produced by High Temperature Materials Inc. using a process similar to that used for pyrolytic graphite. It was deposited at 1,900° C on a substrate of synthetic graphite by decomposition of a mixture of boron chloride and ammonia. The as-deposited density was 2·10 g/c.c.

The test method and equipment used were the same as used for testing graphite and have been previously described[1,2]. All specimens had a gauge section 0·50 in. long by 0·06 in. wide by 0·1 in. thick. The thickness direction was perpendicular to the basal planes. Since the pyrolytic boron nitride test specimen reacted with the graphite specimen grips and the carbon bearing atmosphere of the test furnace at 2,400° C (Fig. 1) test temperatures above 2,200° C were not used.

Table 1 summarizes the tensile data in the basal plane direction obtained for this one lot of pyrolytic boron nitride at a strain-rate of 2×10^{-4} sec^{-1}. Over the temperature-range studied the tensile strength is approximately 1/3–1/2 that of pyrolytic graphite. At room temperature, the tensile strength of pyrolytic boron nitride in the basal plane direction was not markedly different from the strength of hot-pressed boron nitride in the direction parallel to the grain[3,4]. Unlike the hot-pressed material, which showed a

Strain rate $\sim 2 \times 10^{-4}$ sec^{-1}.

decrease in strength to approximately 600 lb./in.^{2} at 1,500° C and then an increase to approximately 4,000 lb./in.^{2} at 2,200° C[4], the pyrolytic material showed a continuous increase in strength with temperature reaching values greater than 16,000 lb./in.^{2} at 2,000 and 2,200° C. Elongation values over the range room temperature to 2,200° C were similar to those reported for pyrolytic graphite and hot-pressed boron nitride.

The reported[4] decrease in strength from room temperature to 1,500° C for hot-pressed boron nitride may be due to the boron oxide which was found to be present in the hot-pressed material[3]. The increase in strength above 1,500° C in the hot-pressed boron nitride may be associated with carbonization of the material. A comparison of the two types of boron nitride after 30 min at various temperatures in the testing furnace is shown in Fig. 1.

Since the pyrolytic boron nitride contains no detectable amount of boron oxide and since there is no appreciable reaction with the test furnace atmosphere up to 2,200° C, the explanation of the increase in strength with temperature may be the same as that proposed for pyrolytic graphite[5], that is, relief of internal stress concentrations with an increase in ductility with temperature.

At temperatures as low as 2,480° C, pyrolytic graphite undergoes a structural transformation[5] when it is deformed in a direction parallel to the basal planes. Since the sublimation temperature of boron nitride is approximately 600° C lower than that of graphite, it was thought that boron nitride might show a similar transformation at 2,200° C or below. Unit cell dimensions calculated from Debye–Scherrer X-ray diffraction patterns obtained from the gauge and butt sections of the tensile specimens indicated that no transformation had occurred. The unit cell height for pyrolytic boron nitride after heating to 2,200° C and after deformation at this temperature was found to be 6·86 ± 0·01 Å. This would indicate a turbostratic structure with no three-dimensional ordering. From the position of the two-dimensional (10) band, a unit cell width of 2·49 ± 0·01 Å was calculated. These dimensions were not different from the values obtained for the as-deposited material. Pease[6] has reported a unit cell height of 6·6612 ± 0·0005 Å and a width of 2·50399 ± 0·00005 Å for boron nitride recrystallized at 2,050° C for 2 h in a nitrogen atmosphere.

Further studies are at present in progress which are aimed at explaining why pyrolytic boron nitride apparently does not transform or recrystallize at 2,200° C.

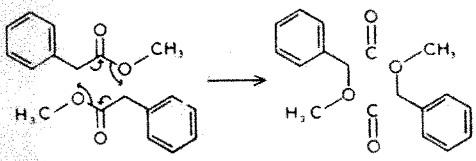
Thermal Decomposition of Methyl Phenylacetate

IN recent years, the mechanism of the thermal decomposition of esters has been thoroughly investigated, and at the present time extensive evidence has been presented to support a *cis* elimination mechanism[1]. Although this mechanism appears to be the major reaction pathway, the presence of secondary decomposition pathways has also been amply verified. Evidence for these mechanisms was reported by Hurd and Blunck[2] in their classic paper, and supporting evidence has been accumulated in the studies on the pyrolysis of methyl phenylacetate and related esters[3–7].

The thermal decomposition of methyl phenylacetate was first reported by Engler and Löw[3] to afford toluene, methanol, carbon monoxide and carbon dioxide. Later, Hurd and Blunck pyrolysed the ester at 625° C, and they reported the presence of benzaldehyde, toluene, formaldehyde, methane, and carbon monoxide as the major products. Since the earlier work did not disclose the existence of benzaldehyde in the decomposition mixture, the pyrolysis was repeated in an attempt to substantiate the presence of this compound. The pyrolysis was conducted at 675° C under Hurd's reaction conditions. The apparatus used for the decomposition consisted of an electrically-heated Vycor tube 28 cm long and 2 cm in diameter packed for a distance of about 20 cm with 'Pyrex' glass beads about 6 mm in diameter. The tube was heated to 675° C, and then 20 ml. of the ester was allowed to drop into the tube at a rate of about one drop per second. The pyrolysate was analysed directly by gas chromatography. At a column temperature of 195° C, 'Apiezon *L*' as the liquid phase, and a helium flow-rate of about 2 bubbles per second, three peaks were recorded which had retention times of 4, 8, and 23 min, respectively. These peaks corresponded to toluene (21 per cent), benzaldehyde (39 per cent), and methyl phenylacetate (40 per cent).

The composition of the products leads one to suggest the presence of an unsymmetrical ether intermediate, since the thermal decomposition of ethers such as benzyl methyl ether affords similar products[8]. In an attempt to isolate such an intermediate, a pyrolysis of the ester was attempted at 150° C for 96 h. The ester was remarkably stable under these conditions, and decomposition was not noted. The ester was then pyrolysed in a distilling apparatus at 210°–215° C for 96 h. The pyrolysis consisted of placing 20 ml. of the ester in a distilling apparatus equipped with a thermometer which extended into the liquid. The flask was then heated to a temperature of 210°–

215° C, and kept at this temperature for a period of 96 h. During this time a small amount of oil (302 mg) distilled from the reaction flask. This oil was analysed directly by gas chromatography. The chromatogram consisted of two peaks which had retention times of 12 and 23 min. These peaks corresponded to benzyl methyl ether (24 per cent) and methyl phenylacetate (76 per cent), respectively. The analysis was conducted at a column temperature of 195° C, 'Apiezon *L*' as the liquid phase, and a helium flow-rate of about 2 bubbles per sec. These results suggest that the ether may be a major intermediate in the thermal decomposition of this ester. The mechanism of the decomposition may involve a bimolecular elimination via a *quasi* six-membered intermediate:



At the present time, the extent of this secondary decomposition pathway in the pyrolysis of esters is being investigated.

Chelates formed by Tin IV with Ethylenediamine Tetraacetic Acid

In a recent publication[1] the chelates formed by tin II with ethylenediamine tetraacetic (EDTA) acid were investigated by *p*H titration, spectrophotometry and polarography. However, some apparent discrepancies have been pointed out by Langer and Bogucki[2], who state that the reported 1 : 1 tin II–EDTA *p*H titration curve is similar to their results for the 1 : 1 tin IV–EDTA chelate, for which compound definite evidence exists for the formation of a hydroxo-chelate.

The properties of tin IV in low acid media are dominated by its tendency to hydrolysis[3] and one might expect that hydrolytic action in the tin IV–EDTA system would be much more marked than for tin II. With this point in mind the *p*H-titration curves for tin IV in the presence of various ratios of the ligand were determined (Fig. 1). Curve *C* for the 1 : 1 ratio shows an inflexion at $a = 3$, where a is the number of equivalents of alkali added per g-atom of metal ion. Thus the tin IV chelate readily undergoes hydrolysis and the species $\mathrm{Sn}Y(\mathrm{OH})^{-1}$, where Y^{-4} is the tetra-negative anion of EDTA, accounts for curve *C* below *p*H 5·0. This is confirmed by curve *D* where no evidence for a 1 : 2 chelate exists. Thus Langer and Bogucki's statement is not borne out by the facts, the tin IV chelate being much more readily hydrolysed than that of tin II. A further distinguishing feature is the pronounced plateau which occurs at about *p*H 7·7 in curve *C* and corresponds to the further release of two protons presumably as a result of hydrolysis of $\mathrm{Sn}Y(\mathrm{OH})_3^{-3}$.

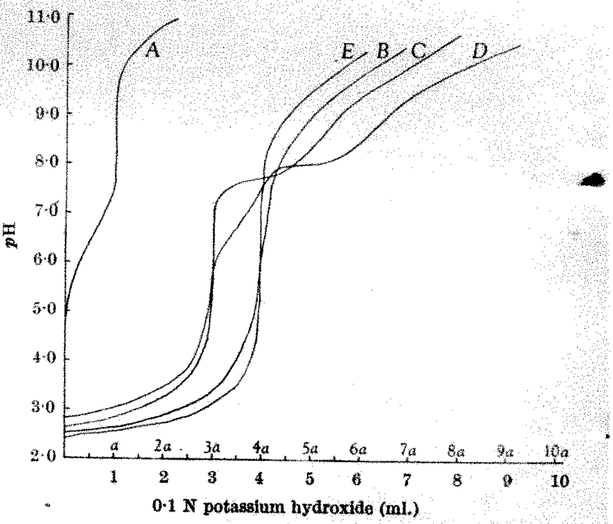

Fig. 1. *p*H titration of the tin IV–EDTA system. Ratio tin IV: H_2Y^{-2}: *A*, 0 : 1; *B*, 1 : 0·5; *C*, 1 : 1; *D*, 1 : 2; *E*, 1 : 0

Curve *B* represents the behaviour for the metal-ligand ratio of 1 : 0·5 with a single inflexion at $a = 4$. This appears to be evidence for a readily hydrolysed 2 : 1 chelate as follows:

$$\mathrm{Sn}^{4} + \tfrac{1}{2}\mathrm{H}_2Y + 3\mathrm{H}_2\mathrm{O} = \tfrac{1}{2}[(\mathrm{HO})_3\mathrm{Sn}Y\mathrm{Sn}(\mathrm{OH})_3] + 4\mathrm{H}^{+}$$

BIOCHEMISTRY

Appearance of Parenterally Administered Proteins in Saliva

Immunochemical investigations have revealed that proteins which react with specific antisera to serum albumin and globulins constitute a substantial fraction of the salivary proteins[1,2]. Thus, barring the possibility of synthesis of proteins with similar immunological properties by salivary glands, albumin and globulins are secreted into the saliva from plasma.

To gain some idea of the permeability of the salivary glands to proteins we have studied the appearance of protein-bound iodine-131 in the whole saliva of man and rabbits after parenteral administration of human albumin labelled with iodine-131. The results provided a basis for administering unlabelled foreign proteins to rabbits; the identification of these proteins in saliva was carried out immunologically.

Man. 300–400 μc. of human albumin labelled with iodine-131 (Abbott Laboratories) were administered intravenously to an adult of each sex. Saliva was collected for 3 h in iced containers and was frozen overnight. The saliva was thawed and was freed of

Table 1. LABELLED PROTEIN IN SALIVA

	Dose				Radioactivity in saliva

5		8·74	9	30	58	2·92		1·5
6		8·74	9	30	92	7·79		14
7		9·15	196	250	70	4·87	2·7	3·2

All counts are corrected for background and interpolated to zero time (administration of dose). Samples were counted for 3 min. Observed counts were within the range of 85–24,000 counts above background.

cell debris and mucin strands by centrifugation in the cold at 18,000*g* for 1 h. Aliquots of the chilled supernatant saliva were removed for measurement of radioactivity in a well-type scintillation counter. Other aliquots were dialysed against cold running water until the radioactivity of the dialysis sac contents (impermeate) remained constant. Still other portions of the saliva were passed through an anion exchange column (Squibb Co. 'Rezikit') and the radioactivity of the effluent was measured.

Rabbits. Labelled Protein : 17–50 μc. of human albumin labelled with iodine-131 were administered to urethane-sedated, pilocarpine-treated[3] adult male rabbits weighing 4·1–4·6 kg. Approximately 100 ml. of saliva which dripped from the mouth over the course of 1·5 h were collected and treated as already described. The effect of varying the amount of radioactivity and the total protein content of the dose, which included added unlabelled carrier human albumin, was noted.

Most of the radioactivity which appeared in the saliva, presumably contributed by inorganic iodide, was dialysable. To confirm the completeness of separation of inorganic and nondialysable iodide, trichloroacetic acid was added to the impermeate. In all cases the precipitate contained all the radioactivity.

Alternatively, passage of centrifuged saliva over an anion exchange resin removed most of the radioactivity. The column effluent as well as a precipitate resulting from treatment of the effluent with trichloroacetic acid contained approximately the same number of counts as the impermeate of the previous experiment. The results of the experiments with labelled human albumin are listed in Table 1. The results show that individual variation exerts a much greater effect on total and non-dialysable radioactivity secreted into saliva than does the μc. of protein-bound iodine or protein content of the dose. The possibility that secreted iodide-131 of saliva may be adsorbed by salivary proteins seems to be excluded by the experiments of Ferguson, who administered Na^{131}I to rabbits and found that all the radioactivity that appeared in the saliva was dialysable[4].

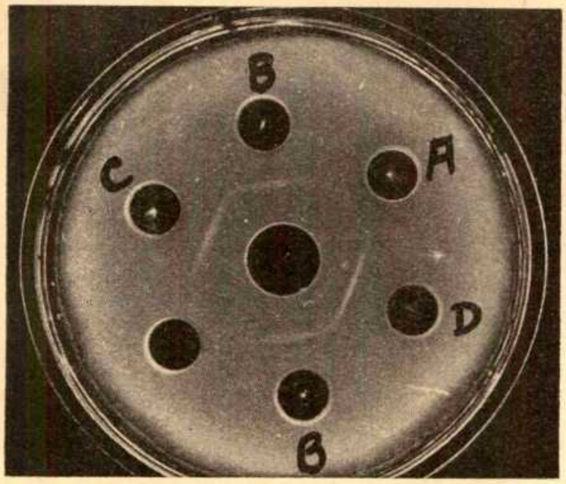

Fig. 1. Centre well, undiluted antiserum (rabbit anti-human albumin). Peripheral wells: *A*, control (25 times concentrated rabbit saliva before administration of human albumin); *B*, standard (1 μg human albumin added to 0·25 ml. of control, unconcentrated saliva *in vitro*); *C* and *D*, 30 times concentrated rabbit saliva after administration of human albumin

Unlabelled Proteins. 0·1–1·0 g amounts of a variety of unlabelled proteins were administered intravenously and 58–123 of saliva were collected as already described. After centrifugation, the saliva was concentrated to 1/25 to 1/50 its volume by vacuum dialysis against isotonic saline with a Schleicher and Schuell collodion sac at 2° (ref. 5).

The concentrated saliva was placed in a peripheral well of an agar diffusion plate. Undiluted antiserum was placed in the centre well. The plate was covered and set aside at room temperature. After 3 days the plates were examined by diffused fluorescent light in an otherwise dark room. Fig. 1 illustrates the type of reaction which appears as a zone of precipitation between the saliva from a rabbit receiving human albumin and specific antiserum. A reaction of identity to specific antiserum was obtained with saliva from a test animal and saliva from a control animal to which the human albumin had been added *in vitro*. Positive results similar to those shown in Fig. 1 were obtained for other protein—antiserum pairs including bovine serum albumin, ovalbumin, chicken and horse serum.

It is clear that parenterally administered proteins may appear in human and rabbit saliva, as demonstrated by radiochemical and immunological techniques. This is evident even with proteins foreign to the rabbit.

Effect of Glucagon on Liver Glycolysis

Several of the known metabolic effects of glucagon are consistent with the possibility that it exerts an inhibitory effect on the Embden–Meyerhof pathway. For example, glucagon promotes ketogenesis[1], inhibits the synthesis of fatty acids[1], and lowers the concentration of pyruvate in the blood[2]. We now wish to report that glucagon influences the glycolytic process in rat liver slices. This effect is probably mediated by 3′,5′-adenosine monophosphate (3′,5′-AMP), the cyclic nucleotide which mediates the glycogenolytic action of glucagon and epinephrine, since both hormones, and the nucleotide itself, exhibit the same effect on pyruvate formation.

Liver slices obtained from male Wistar rats were incubated for 90 min in Krebs–Ringer bicarbonate buffer equilibrated with 5 per cent carbon dioxide and 95 per cent oxygen. In the experiments in which oxygen consumption was measured Krebs–Ringer phosphate buffer was used, with a gas phase of 100 per cent oxygen. Pyruvate and lactate were measured by the methods of Straub[3] and of Barker and Summerson[4] respectively. Oxygen consumption was measured by the direct manometric method. The results will be expressed in terms of micromoles of a metabolite formed or consumed, per 100 mg dry weight of liver per hour. This unit will be denoted by 'R', with a subscript to indicate the particular metabolite referred to.

Table 1 shows the marked reduction in the quantities of pyruvate and lactate in the medium after incubation of the slices in the presence of either of the three agents. It is interesting to note that the degree of inhibition was rather constant, irrespective of the rate of glycolysis in the control slices.

There are, in general, two possibilities to account for the finding of decreased amounts of pyruvate and lactate in the incubation medium. Either a decreased rate of formation or an increased rate of oxidation of pyruvate, or both, could be involved. The latter merits consideration particularly in view of the known calorigenic effect of glucagon in the intact animal[5]. In order to decide between these two possibilities, the experiments were repeated under anaerobic conditions (gas phase 95 per cent nitrogen and 5 per cent carbon dioxide).

The effect of the three agents on lactate production under anaerobiosis was not consistent (Table 2). The reasons for the inconsistency, which contrasts sharply with the situation under aerobic conditions, were not determined. Although the anaerobic experiments were perhaps not conclusive, the measure of the simultaneous rates of oxygen consumption and pyruvate production (Table 3) would appear to indicate that the decreased amounts of pyruvate in the incubation medium cannot be accounted for by an increased oxidation of the metabolite under the influence of glucagon, since 1 mole of lactate requires 3 moles of oxygen for complete oxidation. The small (not statistically significant) increase in oxygen consumption that was observed may have been due to the increased oxidation of fat which probably occurs in the presence of glucagon[1,6].

* No. determinations.

The observation that pyruvate production from glucose, fructose, sorbital, and from endogenous sources is decreased suggests that the initial phosphorylation of hexose units is not the step affected. It has not yet been determined whether the decreased formation of pyruvate is due to an inhibition of one or more of the reactions in the glycolytic sequence or whether it is a consequence of a diversion of an intermediate in the sequence into another pathway.

The foregoing results indicate that at least two metabolic effects occur in the liver as a result of the stimulation of 3′,5′-AMP production by glucagon, namely, glycogenolysis and decreased production of pyruvate. The observation that glucagon exerts a pronounced effect on the rate of pyruvate formation in the liver suggests that it may play an important part in the economy of the mammalian organism.

Drug-induced Hæmolytic Anæmias and the Mechanism and Significance of Heinz Body Formation in Red Blood Cells

SASS-KORTSAK *et al.*[1] recently presented an interesting discussion of the mechanism of drug-induced hæmolytic anæmia and the mechanisms and significance of Heinz body formation in red blood cells. In introducing this subject they cited recent observations of Harley and Maurer. Allen and Jandl, and of their own group as demonstrating that oxidation of hæmoglobin may be an important part of the mechanism of drug-induced hæmolysis. They then stated that, in a review published prior to the contributions of these authors, I[2] had denied this possibility. This is an inadvertent misinterpretation of my published views, which I would like to have the opportunity to correct. I have always regarded the mechanism by which drugs cause hæmolysis to be oxidation of a red cell component, probably hæmoglobin, and have so stated repeatedly[3]. The point which I have questioned is whether methæmoglobin plays an essential part in this process.

In 1955, I wrote: "It may be that Heinz body-forming compounds act as oxidation-reduction 'carriers' oxidizing the red cell component"[3a]. In 1957, I demonstrated that hæmoglobin was altered by acetylphenylhydrazine to a form which oxidized GSH to GSSG, and that this form was not methæmoglobin[3b]. In my 1959 review[2], to which Sass-Kortsak *et al.* refer, I stated: "the administration of a hæmolytic drug causes oxidative damage to either hæmoglobin and/or the stroma of the sensitive cell. Heinz bodies are a visible manifestation of such damage". I would like to emphasize, therefore, that far from denying that oxidative damage to hæmoglobin was responsible for the changes observed in drug-induced hæmolysis, I actually have stated this view repeatedly over the past seven years[3]. Prior to this, the same possibility had been suggested by others[4]: this concept was not originated by me nor by the groups cited by Sass-Kortsak.

The confusion, apparently, has arisen from the part which methæmoglobin plays in the process of oxidative degradation of hæmoglobin. The position which I took in my 1959 review, based on the data available at that time, was that methæmoglobin was not a precursor of the degradation products which were formed on the administration of these drugs. The recent extension of the well-known fact that methæmoglobin production is associated with oxidative degradation of hæmoglobin cannot be considered evidence that methæmoglobin is actually the precursor of hæmoglobin degradation products. The association of methæmoglobin formation with degradation products has long been recognized[4] and could as easily be explained by the reaction pathways schematically presented in Fig. 1*A* as those which have been suggested by Harley and Maurer (Fig. 1*B*).

Since the publication of recent papers in which it was suggested that methæmoglobin was a precursor of degradation products, we have further investigated this problem. We have reasoned that if methæmoglobin is a direct precursor of degradation products of hæmoglobin, then manipulating the steady-state concentration of methæmoglobin should produce predictable effects on the rate of denaturation. Further, complexing methæmoglobin with cyanide might be expected to prevent its further degradation. Our *in vitro* findings, which are published in detail elsewhere[5], are essentially that: (1) decreasing the steady-state level of methæmoglobin by adding methylene blue to the incubating medium did not inhibit destruction of 'intact hæmoglobin'; (2) increasing the methæmoglobin concentration by pre-incubating red cells with sodium nitrite did not increase oxidative denaturation of hæmoglobin; (3) complexing methæmoglobin with cyanide decreased

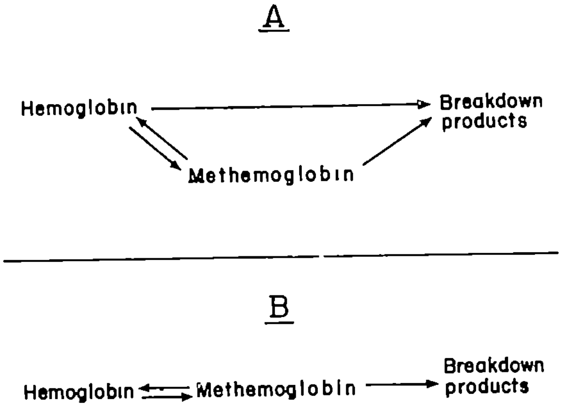

Fig 1. Two possible pathways of oxidative degradation of hæmoglobin. The pathways shown in *A* seem to me to be equally likely, or more so, than the reaction pathways shown under *B*

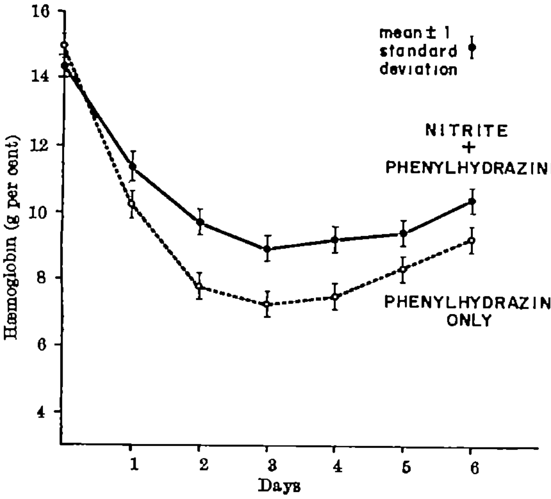

Fig. 2. The effect of methæmoglobinæmia on phenylhydrazine-induced hæmolysis in rats. Each curve represents the mean of the values obtained in six animals. Induction of methæmoglobinæmia with nitrite not only failed to increase hæmolysis, but also actually resulted in some degree of protection

the formation of the small quantities of insoluble hæmoglobin derivatives, but did not decrease the formation of quantitatively more important degradation products.

A further *in vivo* investigation also has some bearing on this matter. If methæmoglobin were a precursor of further hæmoglobin degradation products, one should expect that the induction of methæmoglobinæmia by sodium nitrite would potentiate the hæmolytic effect of a hæmolytic agent like phenylhydrazine. A group of 6 rats has been given 50 mg of sodium nitrite per kg body-weight subcutaneously. This quantity of sodium nitrite has been shown previously to induce methæmoglobinæmia of more than 3 h duration[6]. The peak-levels of methæmoglobin are achieved at the end of 60–90 min. In these studies, methæmoglobin values of 49–60 per cent were achieved after 60 min. 75 min after the injection of nitrite, the six nitrite-treated rats and six control rats which had not been pre-treated with nitrite were given 20 mg of phenylhydrazine hydrochloride subcutaneously.

The hæmoglobin values of these animals are presented in Fig. 2. Not only was there no enhancement of phenylhydrazine-induced hæmolysis by the injection of this methæmoglobin-forming agent, but also there was, if anything, actually protection against hæmolysis. Similar results were obtained in another experiment in which nitrite injection was started before the administration of phenylhydrazine, and an additional injection of nitrite was given 6 h after the first one. Thus, in spite of approximately 12 h of methæmoglobinæmia associated with the injection of phenylhydrazine, there was no enhancement of hæmolysis.

In order to duplicate more closely the *in vitro* studies which have been reported by Sass-Kortsak *et al.*[1], I have attempted to repeat these studies by the use of vitamin K_3. In rats, this compound was not hæmolytic, even when doses as large as 20 mg were given to each animal. It is possible that the results obtained in these studies with phenylhydrazine are not strictly applicable to the problem of hæmolytic activity of vitamin K_3; however, most investigators have viewed the mechanism of hæmolysis by the various oxidant drugs as probably being identical. I am also inclined toward this point of view.

While I do not regard these investigations as conclusive, neither do I find that any convincing evidence has been presented that methæmoglobin plays an important part in the oxidative degradation of the hæmoglobin. These findings are difficult to reconcile either with the view that methæmoglobin is a precursor of further hæmoglobin degradation products, or with the view[1] that methæmoglobin enhances hæmolysis by draining the red cells' supplies of TPNH.

WE agree with Dr. Beutler and admit that one of our remarks in our original communication may be easily misinterpreted and may constitute an "inadvertent misinterpretation" of Dr. Beutler's published views.

Beutler further discusses the role of methæmoglobin in the process of oxidative denaturation of hæmoglobin and presents the results of experiments which do have an important bearing on this question. We agree with Beutler that the question whether the formation of methæmoglobin is an essential step preceding the oxidative denaturation of hæmoglobin is unsettled, and the results of his recent experiments with acetyl-phenylhydrazine constitute an argument against this possibility. Whether other oxidant drugs (for example, 'Menadione') have an effect similar to acetyl-phenylhydrazine remains to be determined.

In addition to the foregoing, we feel that the question whether oxidative denaturation of hæmoglobin (by whatever route) is the decisive step in the production of drug-induced red cell damage leading to hæmolysis *in vivo* is unsettled as well. In our original communication, we discussed the merits and the possibility of an alternative mechanism proposed by Ernster[1], fully realizing and making it clear that there is no proof of the validity of this hypothesis as well. Some of Beutler's recent experiments do cast in fact some measure of doubt on this possibility. The fact that nitrite-induced methæmoglobinæmia did not accelerate a hæmolytic crisis produced by acetyl-phenylhydrazine is a serious objection. However, there may be some doubt whether this observation can be applied to all other oxidant drugs. Moreover, the production of methæmoglobin by nitrite may be accompanied by the formation of nitroso-hæmoglobin and nitroso-methæmoglobin[2], which may then influence the system in an unpredictable manner.

Nevertheless, these objections are minor and may not be convincing, and, therefore, Beutler's findings are of great interest and importance and will, no doubt, stimulate further work towards the clarification of the mechanism of drug-induced hæmolysis.

Eriochrome Black *T* as a Protein Dye

BINDING of eriochrome black *T* to protein was suspected during experimental ultramicro-titration of solutions containing serum proteins, when using eriochrome black *T* as indicator, because of difficulty in obtaining a value for the indicator blank titration.

The binding was confirmed by dyeing protein on cellulose acetate membrane. The use of eriochrome black *T* as a protein dye following electrophoresis of serum on cellulose acetate was therefore investigated. The dye bath solution which gave complete staining of the protein fractions after electrophoresis was 0·1 per cent w/v eriochrome black *T* in alcoholic glacial acetic acid (9 vols. + 1 vol.). This dye solution is stable for at least three months.

Electrophoresis of the serum was carried out on 3 × 1 in. strips of cellulose acetate, using the buffer solution recommended by Afonso[1], at 1·5 m.amp. per strip for 1 h. The strips were taken directly from the electrophoresis chamber and placed in the dye bath for 1 h. The excess dye was removed, to leave a clear background, by washing in a bath of 5 per cent v/v glacial acetic acid in 50 per cent alcohol. After a final wash in water the strips were dried between filter papers under light pressure. The stained dried strips were cleared with liquid paraffin and scanned with a modified EEL scanner using an *OGR* 1 broad spectrum filter. An example of the trace from a scanned strip is shown in Fig. 1.

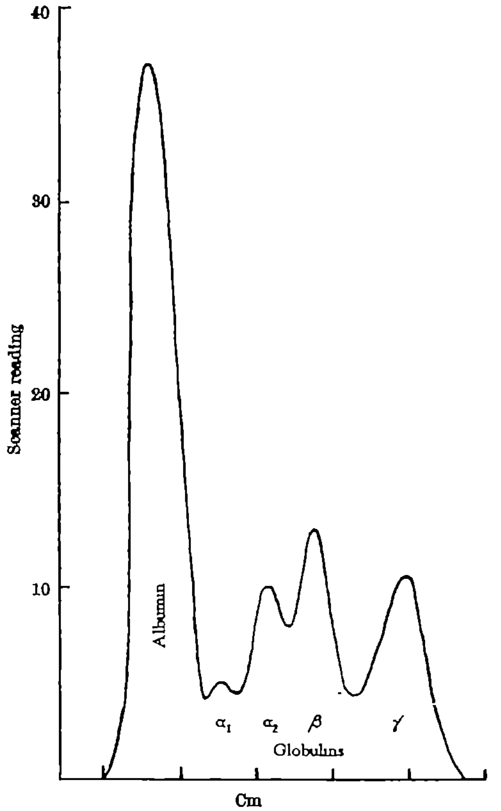

Fig. 1. Scanned curve after electrophoresis and staining of approximately 2 μl. of serum, total protein 6·4 g/100 ml., albumin 3·5 g/100 ml.

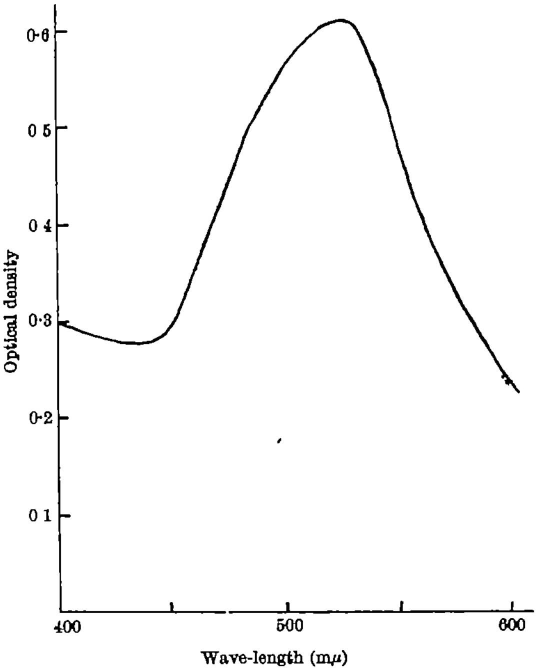

Fig. 2. Absorption spectrum of eriochrome black *T* stained protein on cellulose acetate dissolved in chloroform–alcohol

Spectrophotometric examination of the dyed protein fractions was carried out after placing the required section of the dry stained strip in 5 ml. of a mixture of 9 vols. chloroform and 1 vol. alcohol and allowing to stand, with occasional shaking, for 5–10 min. At the end of this time the cellulose acetate membrane had dissolved leaving the dyed protein in solution. Very large amounts of dyed protein occasionally delayed solution of the cellulose acetate, but the addition of 2 drops of 'Hyamine 2389' helped to give complete solution and the original colour of the dyed protein was restored by adding 2 drops of glacial acetic acid and mixing. The absorption spectrum of the dyed protein from cellulose acetate membrane dissolved in the chloroform–alcohol mixture is shown in Fig. 2. An absorption maximum was found at 525 mμ.

Eriochrome black *T* appeared to be a sensitive dye for protein so the dye bath, as used to stain electrophoretic strips, was used to stain the lines of precipitate obtained during immuno-double diffusion on cellulose acetate as described by Consden and Kohn[2]. The precipitated protein stained readily and it was found that post-staining the strip with nigrosine did not enhance the staining of faint lines.

During the initial experiments with the dye bath two methods of precipitating the protein on the cellulose acetate following electrophoresis were tried using trichloroacetic acid. The first was to use a separate fixing bath of 5 per cent w/v trichloroacetic acid in 95 per cent methanol before staining and the second was to add trichloroacetic acid to the dye bath to give a concentration of 5 per cent w/v. By both these methods it was found that the albumin band did not stain. The precipitation reaction of the trichloroacetic acid had therefore blocked the albumin dye binding sites to eriochrome black *T*. This is direct experimental evidence of a difference in the dye binding of albumin and globulins which agrees with the suggestion by various authors of using a factor to correct for different dye binding capacities of albumin and globulins with other dyes.

Human Casein and its Caseino-glycopeptide

When rennin is allowed to react with caseins prepared from milk of different ruminant species at neutral *p*H and in the presence of calcium, para-casein precipitates and the supernatant contains a glycopeptide, called caseino-glycopeptide[1]: it does not dialyse, and remains soluble in 12 per cent trichloroacetic acid (TCA). We prepared and analysed recently the caseino-glycopeptides from cow, goat and sheep caseins, which are analogous but not identical substances[1]. In the case of cow's casein the glycopeptide was obtained from κ-casein by rennin digestion in the absence of calcium[1]. κ-casein has been analysed[2] and seems to be the specific substrate for rennin. In this paper we want to report the amino-acid composition of human casein and to comment on some results concerning its digestion by rennin.

Human casein has been prepared by several methods[3,4]. We used the following procedure: pooled human milk was defatted by centrifugation and dialysed against water at 2° in the presence of 5 parts per thousand of toluene The casein was precipitated by acidification with hydrochloric acid to *p*H 4·6. If the dialysis is omitted the precipitation does not occur regularly. The casein was washed with water, alcohol and ether: during this treatment, 35 per cent of the initial weight is lost and the nitrogen content increases from 8·6 to 14·8 per cent.

Human casein has been analysed: the amino-acids have been determined after total hydrolysis (6 N hydrochloric acid; 110°; 18 h) with a Technicon auto-analyser following the method of Piez and Morris[5], tryptophan according to Spies and Chambers[6], the amino-sugars according to Rondle and Morgan[7] and *N*-acetylneuraminic acid (Nana) according to Warren[8]. The results are given in Table 1.

Table 1. Composition of Human Casein and of Human Caseino-Glycopeptide

Amino-acid or sugar	Casein (g/100 g casein)	Caseino-glycopeptide (molar ratio)
Asp	7·5	3
Thr	4·35	6
Ser	4·8	4
Glu	18·3	5
Pro	10·9	5
Gly	1·8	3
Ala	2·8	5
Cys	0·95	0
Val	4·85	3
Met	0·7	0
Ileu	4·4	3–4
Leu	10·8	1
Tyr	5·1	0
Phe	3·8	0
Try	2·4	0
Lys	8·85	3
His	2·15	0
Arg	2·05	0
Galactose	2·55	+ see text
Galactosamine	2·20	+ see text
Sialic acid	0·37	+ see text

The amino-acid analysis presents important differences with the results reported a great number of years ago by Plimmer[9], Beach *et al.*[10] and Williamson[11], especially concerning Gly, Met, Asp and Lys. Our sugar and amino-sugar content is higher and the Nana content lower than those reported by Johansson and Svennerholm[12]. Human casein has more Cys and less basic amino-acids than cow's casein.

Carboxypeptidase liberates after 2 h at *p*H 7·8 and 37° the following amino-acids from human casein: Val (0·25 μM/mg casein), Leu (0·12), Thr (0·08) and Ala (0·04). The amino-acids liberated from κ-casein (cow) were Val, Thr, Ala and Ser[1]. By Sanger's method it was possible to characterize some *N*-terminal Arg.

At *p*H 6·8, human casein, even in the presence of calcium, precipitates only with difficulty during the digestion with rennin (0 05 unit/ml. 1–2 per cent protein solution). At *p*H 4·6, human casein precipitates, but in the presence of rennin a soluble substance(s) becomes present in the supernatant.

By analogy with the previously examined caseino-glycopeptides[1], we tried to prepare the human caseino-glycopeptide in the same manner: rennin digestion at *p*H 6·8, precipitation by 12 per cent TCA, dialysis of the supernatant and lyophilization of the clear, not dialysable fraction containing the caseino-glycopeptide. In the absence of rennin the supernatant obtained after treatment of human casein with 12 per cent TCA presents some nitrogen-containing substances. After dialysis and hydrolysis of the non-dialysable fraction, its amino-acid content has been determined. It is very low (0·6 per cent). In the presence of rennin, the supernatant obtained after treatment of human casein with 12 per cent TCA presents a higher nitrogen content. But this increase is not regularly obtained and in the course of five experiments we observed it only twice. This fact may be explained by the presence in some lots of human casein of substances preventing the rennin action. Keller[13] also reported the formation of a nitrogen-rich substance during the rennin digestion.

The substance formed after rennin digestion is called human caseino-glycopeptide. Its amino-acid and sugar content is given in Table 1. The molar ratios of the different amino-acids are very closely related to those reported for the caseino-glycopeptides of cow, goat and sheep[1]. In this connexion are especially noted the characteristic high content in Thr and Ileu and the lower ones in Ser and Leu (Thr/Ser = 5/3; Ileu/Leu = 3/1): it should be realized that human casein contains nearly the same proportion of Thr and Ser and more Leu than Ileu as is also found in cow's casein. As with all previously examined caseino-glycopeptides, the human one contains only traces of aromatic and sulphur-containing amino-acids which may belong to some traces of remaining casein, no histidine or arginine and a great quantity of sugars, namely, 8·37 per cent galactose, 6·36 per cent galactosamine and 1·26 per cent *N*-acetylneuraminic acid Carboxypeptidase liberates here again Val. Contrary to the other caseino-glycopeptides, we have found a high content of Gly.

In this communication we have shown that after rennin digestion of human casein which has been analysed, a substance appears which is soluble in 12 per cent TCA and not dialysable: it seems to be very closely related to the previously studied caseino-glycopeptides. But it has not been determined until now if human casein contains a component similar to the κ-fraction of cow's casein. As human casein is not so sensitive to rennin as cow's casein, Imada *et al.*[14] suggested that such a fraction may fail, but the presence of our caseino-glycopeptide fraction is not in favour of such an interpretation.

We thank Mrs. Bertrand (Ecole de Puériculture, Paris) for human milk. We also thank Prof. E. Lederer and Dr. G. Mocquot for their interest and encouragement.

Fractionation of Nitrogenous Compounds from Corn Leaves

INCREASED resolution of many components of complex biological mixtures has been accomplished by the use of substituted cellulose compounds in chromatography. Calf lens proteins have been fractionated into ten components on DEAE (diethylamino-ethylcellulose) by Spector[1]. Wheat glutin was fractionated on carboxymethyl-cellulose columns into four components by Woychick *et al.*[2]. DEAE columns were used to purify β-glucosidase from yeast by Duerkson and Halvorson[3]. Changes in the elution pattern of proteins of white potato tubers infected with *Phytophthora infestans* were found when extracts were chromatographed on DEAE[4].

Extracts of soluble components of healthy leaf tissues were made from 2 inbred differential corn lines, *B*38 and *B*14[5], at the 3–5 leaf stage. The extracts were prepared by grinding the frozen leaf tissue at 4° C in 2–3 v/w of ice-cold 0·05 M phosphate buffer *p*H 6 8. Following grinding, the cell wall materials, along with other debris, were removed by centrifugation at 5,000*g* for 15 min. Chloroplasts were removed by centrifugation at 15,000 r p.m. (19,600*g*) for 1 h. The resultant supernatant was clear and light yellow in colour. The proteins in the supernatant were stabilized by adding sucrose to a final concentration of 12·5 per cent w/v. Polyhydroxy compounds, for example sucrose, were reported by Heitfuss *et al.*[6] to stabilize plant proteins. The fractionations were performed on these extracts without further purification. Protein nitrogen values were obtained using the method of Warburg and Christian[7] or by Lowry's modification[8] of the folin–phenol method. A quantitative determination was made by determining the amount of protein in the whole extract and subtracting the amount remaining in the supernatant after treatment with 10 per cent trichloroacetic acid.

Electrophoresis of these extracts on paper indicated only 2 or 3 bands when stained with bromphenol blue, nigrosin or buffalo blue black. The most rapidly moving band was broad and diffuse followed by 1 or

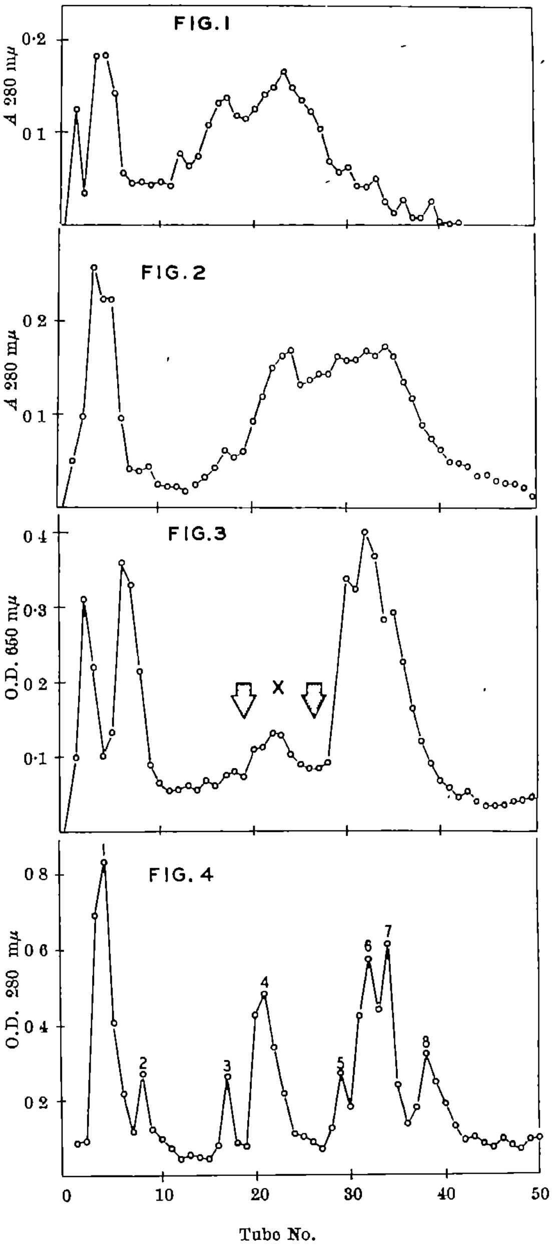

Fig. 1. Elution patterns of the inbred corn line *B*-14 using a limit buffer 2·0 M sodium chloride. Fig. 2. Elution pattern of the same material as in Fig. 1 using 1·0 M sodium chloride as the limit to solution. Fig. 3. Elution pattern of inbred corn line *B*-38 using 0·5 M sodium chloride as the limit solution. Nitrogenous compounds were detected in Figs. 1, 2 and 4 by the absorbance at 280 mμ and 260 mμ. The compounds reported in Fig. 3 were detected by the folin–phenol method; the optical density at 650 mμ represents the peak used for detection. Fig. 4 represents the elution pattern of *B*-14 0 5 M sodium chloride as the limit solution. Eight rather sharp peaks are discernible in this system

2 narrow sharp bands. Agar-gel electrophoresis revealed 4 discrete bands. A broad band migrated most rapidly toward the anode followed by three sharp bands. To facilitate the further separation of the nitrogenous material, fractionation by means of DEAE column chromatography was utilized.

Columns were prepared from DEAE (Eastman organic chemicals lot No. 1056) in 1 × 30 cm 'Pyrex' chromatography tubes fitted with a sintered glass disk. Columns were packed to a height of 20 cm in the manner described by Spector[1].

A gradient system consisting of two cylinders of equal volume connected by a siphon and stirred by a magnetic system in the delivery side was used successfully to obtain reproducible linear gradients. Various combinations of starting and limit solutions were tried. Gradients constructed with phosphate buffer at 0·005 M or less as the starting solution and sodium chloride at different concentrations as the limit solution were used in this investigation. Figs. 1, 2, and 4 indicate the elution patterns utilizing 2·0, 1·0, and 0·5 M sodium chloride as the limit solution.

The extracts were placed on a nearly dry column and layered with phosphate buffer. When the sample had penetrated below the surface of the packed DEAE, the gradient system was connected.

A gradient involving 400 ml. total volume required 23–25 h to pass through the column. 6-ml. fractions were collected.

The patterns in Figs. 1, 2 and 3 indicate an increasing separation of components in extracts of *B*–14 grown at 28° C. The first two peaks in each pattern shift very little in each change of limit buffer until 0·5 M sodium chloride is used (Figs. 3 and 4). The area covered by the majority of compounds included in the tubes Nos. 10–40 shows increased definition as the concentration of limit solution is lowered. A total of 8 principal peaks or ridges of peaks are detectable by the use of this method, numbered 1–8 in Fig. 4. The increase in number of components located by this method is at least 100 per cent over electrophoresis on either agar or paper.

Application of DEAE chromatography with the increased resolution of nitrogenous compounds indicates biochemical differences in inbred lines *B*14 and *B*38 (Figs. 3 and 4).

Fig. 3 shows the elution pattern for inbred corn line *B*38 grown at 20° C. A difference in the elution pattern in the region between the arrows (*X*) in Fig. 3 was found in plants grown at 28° C. In this region the material fractionated from plants grown at 28° C did not show a peak. Apparently an influence of temperature on the biochemical composition of *B*38 is detected by the sensitivity of DEAE chromatography.

Attempts to isolate and characterize the material from region (*X*), Fig. 3, have been unsuccessful. *In vacuo* drying has not been successful in concentrating the material. The compounds found in area *X*, Fig. 3, are labile to dialysis with a half-life of 24 h at 4° C.

Future research will be directed toward identifying and characterizing the components in this area (*X*) as influenced by temperature and to a further definitive separation of these components.

This communication is submitted with the approval of the Director of the Wisconsin Agricultural Experiment Station. The investigations were supported in part by research grant *E* 1248 (*C*5*S*1), Division of Allergy and Infectious Diseases, U.S. National Institutes of Health. We thank Dr. A. L. Flangas for suggesting this study and providing the materials used.

Citric Acid in Tissues of Normal and Dystrophic Animals

THE exact role of citric acid in the body is not yet fully understood. However, citric acid in body fluids seems to adjust itself to calcium-levels; when calcium is increased, citric acid is increased too[1].

In 1937, Fenn and Goettsch[2] found in dystrophic rabbits on a vitamin E-deficient diet elevations in calcium content of muscle as much as 3–5 times normal. These findings led us to the speculation that citric acid may also be increased, and we found this to be so.

First we investigated rabbits on a vitamin E-free diet[3] with and without α-tocopherol supplement. (We thank Dr. I. Weinstock and his staff for providing these animals.) The animals were decapitated and blood was collected directly into centrifuge tubes. Fresh tissue samples of muscle, liver and kidney were weighed and immediately put into tubes containing trichloroacetic acid. The tubes were heated in a water bath of about 80° C with frequent stirring until the tissue disintegrated to a fine powder; finally 1 ml. of 100 per cent trichloroacetic acid was added. The tubes were cooled and the volume was adjusted to 10 ml. After centrifuging an aliquot was taken for analysis[4,5]. As shown in Fig. 1, citric acid was greatly increased in muscle, less so in liver and very little in kidney. There was no increase in serum. While the concentrations of citric acid in muscle and liver of the control animals were almost the same, these levels were much higher in kidney tissue.

We investigated also another species, namely, mice with hereditary muscular dystrophy. The 129/*Re-dydy* dystrophic animals and the new *C*57 *BL*/6*J-dy* type described by Russell *et al.*[6] were obtained from the Roscoe B. Jackson Memorial Laboratories, Bar Harbor, Maine. The results are shown in Fig. 2. In spite of the gross differences between the citric acid concentrations of normal mouse muscle and normal rabbit muscle, the increases in dystrophic muscles are of the same order of magnitude in both species.

The fact that the increase of citric acid is greatest in muscle may point to its specificity in this abnormal state. Though its role is not completely clarified, citric acid may act as a chelating substance in the interaction of minerals and trace elements. We believe this is the first time that citric acid has been investigated in dystrophic muscle. Studies of human muscle are in progress.

Biochemical Changes in Pigeon Breast Muscle Mitochondria following Nerve Section

NUMEROUS chemical and biochemical investigations have been performed on muscle in the course of denervation atrophy, but very few observations have been made on isolated mitochondria. Aloisi *et al.*[1], in a preliminary investigation on denervated pigeon breast muscle, observed a diminished yield of the mitochondrial fraction and a lowered oxidative ability of the mitochondria towards α-oxoglutarate 15–18 days after nerve section.

Our work was carried out on pigeons denervated from a few hours up to 14 days to see whether any biochemical lesion occurred in muscle prior to the appearance of morphological atrophy of the tissue.

Table 1. CHANGES IN PIGEON BREAST MUSCLE MITOCHONDRIA THREE DAYS AFTER NERVE SECTION

		Normal	Denervated	Change (%)
Pyruvate	$Q_{O_2}^{pr}$	81·0	60·5	−25
	P : O	2·59	2·32	−10
	R.C.I.	2·6	2·0	−36
α-Oxoglutarate	$Q_{O_2}^{pr}$	66·5	55·3	−17
	P : O	2·72	2·97	+9
	R.C.I.	3·2	2·2	−48
ATPase (μmoles P/mg pr./h)				
Not activated		3·75	1·72	−54
DNP-activated		8·28	3·37	−59
Mg^{++}-activated		13·40	11·65	−13
Cytochrome oxidase				
Mitochondria (μl. O_2/mg pr./h)		3,081	2,494	−17
Homogenate (μl. O_2/g fresh tissue/h)		833	464	−44
←Mitochondrial yield (mg pr./g fresh tissue)		3·25	3·85	—

R.C.I., respiratory control index.

The wing nerve plexus of one side was severed under ether anæsthesia. Mitochondria were isolated from the pectoralis major muscle and assayed for a number of variables expressing their functional abilities related to energy metabolism. The mitochondria of the contralateral muscle were used as controls. The isolation and testing methods were essentially the same as used by Azzone *et al.*[2]; cytochrome oxidase activity was measured following the method of Schneider and Potter[3].

No significant changes of the measured variables were observed in the first three days following nerve section. After this interval some modification became apparent in isolated mitochondria (Table 1); their oxidative ability towards pyruvate and α-oxoglutarate decreased significantly and the same happened for cytochrome oxidase activity. These changes progressed with time as illustrated in Figs. 1*A*, *B*. The addition of coenzyme *A*, thiamine pyrophosphate, and diphosphopyridine nucleotide to the mitochondrial preparations did not raise their oxygen uptake. The adenosine triphosphatase (ATPase) activity of the mitochondria was concomitantly lowered. Both the ATPase activity without added activators and the 2,4-dinitrophenol (DNP)-activated one were affected; however, the activation by DNP, as expressed by the ratio DNP-activated ATPase/non-activated ATPase, was not significantly modified in mitochondria from denervated muscle (Fig. 1*C*). The addition of magnesium caused an increase of ATPase activity of the same order in normal and 'denervated' mitochondria; this behaviour supports the suggestion[3,4] that magnesium-activated ATPase activity of muscle mitochondrial preparations is in fact due to some contaminating structures, possibly fragments of sarcoplasmic reticulum.

The coupling of electron transport with phosphorylation was barely affected three days after denervation. However, the modification was limited to the respiratory control index and to the phosphorus : oxygen ratio for pyruvate, which resulted slightly lowered. Thus, from the fourth day onward after nerve section the isolated mitochondria appeared as 'loosely coupled'.

With succinate as a substrate five days after nerve section a diminution of about 50 per cent of the phosphorus : oxygen ratio was observed; this change remained constant during the following days. We have circumstantial evidence that this decrease of the phosphorus : oxygen ratio was not due to uncoupling in the usual sense, but to a loss of ATP from the denervated muscle mitochondria, in accordance with

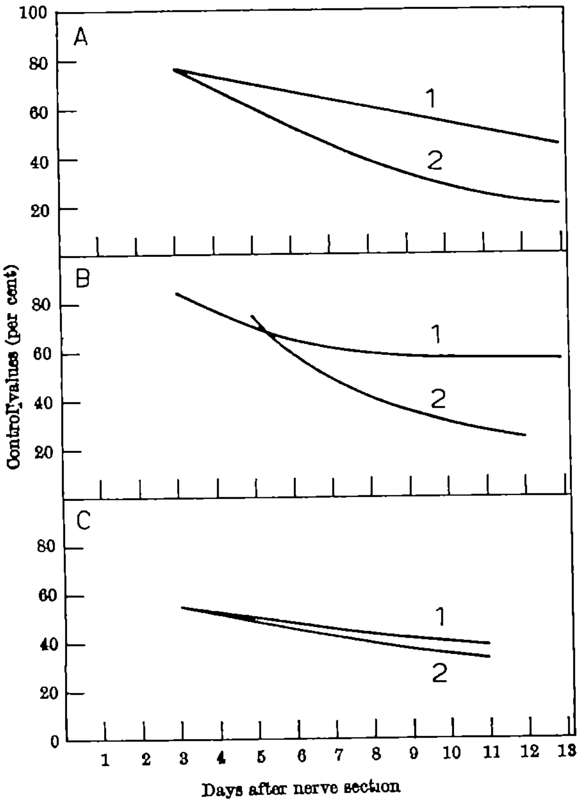

Fig. 1. Effect of denervation on pigeon breast muscle mitochondria activities

*A*1, pyruvate oxidation (control mean $Q^{\text{pr}}_{O_2}$ = 66·4); *A*2, α-oxoglutarate oxidation (control mean $Q^{\text{pr}}_{O_2}$ = 70 9). *B*1, cytochrome oxidase activity (control mean $Q^{\text{pr}}_{O_2}$ = 2004); *B*2, mitochondrial yield (control value = 2·99 mg pr./g fresh tissue). *C*1, non-activated ATPase (control mean value = 8·70 μmoles phosphorus/mg pr./h); *C*2, DNP-activated ATPase (control mean value = 6·20 μmoles phosphorus/mg pr./h)

some recent views advanced[5] on the role of ATP in the functional link of succinate with the respiratory chain.

Also cytochrome oxidase activity of both the whole homogenate and isolated mitochondria began to diminish three days after nerve section and soon reached values around 50 per cent of normal ones. The mitochondrial yield remained normal up to the fifth day, then it dropped rapidly to reach levels around 25 per cent of the control (Fig. 1*B*).

The parallel decrease of the rate of respiration with pyruvate and α-oxoglutarate as substrates and of non-activated and DNP-activated ATPase activity, together with the results of the cytochrome oxidase assay, seem to indicate that as a result of nerve section muscle mitochondria undergo depletion of their enzyme contents followed by a diminution of the mitochondrial complement of the fibre.

These biochemical regressive changes of the main energy-producing structures of the cell precede histological atrophy of the muscle and most probably contribute to its pathogenesis; however, the relatively long interval between nerve section and the onset of the first detectable biochemical changes in mitochondria, together with the kinetics and the sequence of the modifications observed, strongly suggest that other functional sites of the cell are affected by denervation before mitochondria.

PHYSIOLOGY

Rate of Oxygen Uptake of Erythrocytes of Vitamin E-deficient Rats

Vitamin E-deficient animals are much more sensitive to oxygen under high pressure than are normal animals[1]. In particular, the erythrocytes of the deficient animals, on exposure to oxygen under high pressure, rapidly undergo a remarkable degree of hæmolysis *in vivo*, which is prevented by even very small doses of tocopherol[2,3]. It is known[4,5] that conditions which increase the rate of oxygen consumption of the whole animal increase its sensitivity to oxygen under high pressure, and there is evidence[6] that vitamin E deficiency falls into this category. It seemed important, therefore, as a first step in the study of this type of hæmolysis, to find out if vitamin E deficiency was associated with any change in the rate of oxygen consumption of the erythrocytes.

Sixteen rats, comprising 2 litters, each containing 4 of either sex, were allotted at random to 2 groups, one of which was given a diet deficient in vitamin E and the other the same diet with the addition of α-tocopherol acetate (10 mg/week). The composition of the diet, and the procedure adopted in administering the fat-soluble vitamins, have been fully described in earlier papers[2,3]. At the age of 16 weeks the animals were lightly anæsthetized with ether, a few drops of tail blood were taken for the dialuric acid test of Rose and György[7] and the animals were then bled from the femoral artery into heparinized containers. Passage through sintered glass filters with gentle suction removed approximately 90 per cent of the leucocytes. The blood was then centrifuged and the erythrocytes washed in 0·9 per cent sodium chloride solution and suspended in a volume of Krebs's buffer solution such as to give final hæmatocrit values of approximately 66 per cent. The rate of oxygen uptake of 1 ml. samples, after shaking for 30 min to ensure complete saturation of hæmoglobin with oxygen, was then determined over 2 h in 5-ml. Warburg flasks at 37° C. After this time, some degree of hæmolysis was obvious in the samples from deficient rats and was accompanied by a falling off in the rate of oxygen consumption.

The dialuric acid test, presence of uterine pigment and loss of testicular weight showed that none of the 'controls' and all the 'deficient' rats were in fact vitamin E deficient.

There was a clear difference in the rates of oxygen uptake of the red cells from the 2 groups, that of the cells from the deficient animals being twice as great as that of the controls—0·090 ± 0·009 μl./mg dry wt./h compared with 0.045 ± 0.006 µl./mg dry wt./h ($P < 0.0001$).

There seems no doubt, then, that vitamin E deficiency is associated with an increased rate of oxygen uptake by the erythrocytes. Vitamin E-deficient red cells do in fact hæmolyse *in vitro* under a variety of conditions, due it is suggested to uninhibited peroxide formation[8], a process which may occur independently on exposure to oxygen under high pressure[9]. It is also known that at least some types of hæmolysis, for example, that due to methylene blue, are associated with an increase in erythrocyte oxygen consumption[10]. The problem of relating these facts to hæmolysis occurring on exposure to oxygen under pressure remains.

We thank Dr. P. Grant of the Department of Biological Chemistry, University of Aberdeen, for advice on methods of removing leucocytes from whole blood, and Dr. R. M. Cormack, of the Department of Statistics, University of Aberdeen, for help with the statistical analysis.

Adipose Tissue Lipoprotein Lipase Activity in Rats of Two Different Ages

THE physiological part played by the clearing factor or lipoprotein lipase has not been fully established in man[1]. The parenteral administration of heparin to normal human adults after a fatty meal and overnight fasting has been shown to cause the appearance of this enzyme in the plasma[2,3].

Heparin acts by mobilizing the enzyme from the tissues where it is normally present and effecting its rapid attachment to the substrate. The adipose tissue of various animals is a common source of this enzyme and that this may apply to man as well has been suggested by the experiments of Renold and Marble[4]. Other workers, however[5,6], failed to find any lipoprotein lipase activity in human adipose tissue.

In an attempt to explain such an absence of enzyme from the human adipose tissue Angervall speculated[5] that the lipase might be present only in growing subjects but not in adults, since he found appreciable quantities of the enzyme in the adipose tissue of chickens, and only negligible amounts in that of hens. No account, however, was given of attempts to confirm this hypothesis in other species.

I tested human breast adipose tissue taken from middle-aged women on whom mastectomy was performed for carcinoma of the breast. The method used is described here. No lipoprotein lipase activity was found on the human adipose tissue so tested.

The human adipose tissue, however, tested by Angervall[5], Engelberg[6] and by me was taken during surgery and therefore from fasting subjects, and as fasting decreases considerably the lipoprotein lipase activity of the adipose tissue of rats[7,8] it is conceivable that the absence of any such activity in the human adipose tissue was due, at least partly, to the fact that the subjects whose adipose tissue was tested were fasting.

On the other hand, the striking differences that Angervall[5] found between chickens and hens offer another possible explanation.

Since the effect of age on the adipose tissue lipoprotein lipase activity has not been tested on mammals I decided to determine this activity in the adipose tissue of rats at two different ages.

Three experiments were performed, in which 10 young (4–5 weeks old) and 9 old (more than 5 months old) male Wistar rats, fed on a standard diet, were killed by decapitation, and fragments of the anterior part of their epididymal fat bodies were assayed for lipoprotein lipase. The method described by Cherkes and Gordon[7] was utilized, modified to the extent that an activated emulsion of cottonseed oil ('Infonutrol') was used as a substrate and that the incubation of the tissue was carried out for 40 min in a Krebs–Ringer bicarbonate buffer. The concentration of heparin sodium in the medium was 3·4 mg (384 units heparin sodium B.P.) per litre of medium. In preliminary experiments we found that up to this level a ten-fold increase in the concentration of heparin caused a two-fold increase in the detachment of the enzyme from the tissue. With a further rise of heparin, however, there was no more increase in the enzyme detachment from the tissue nor was there any decrease.

The free fatty acids evolved were determined using a modification of Dole's method[9]: 2 ml. of the heptane phase were pipetted into conical tubes to which 2 ml. of nile blue indicator[10] were added. The results were expressed in units of lipoprotein lipase per gram of wet adipose tissue[6,7], one unit representing the amount of lipase which would release one µequiv. free fatty acid/h.

The average enzyme activity so defined was found to be $19{\cdot}36 \pm 8{\cdot}25$ (mean $\pm$ $S.D.$) units for young and $2{\cdot}92$ (mean $\pm$ $S.D.$) units for old rats ($t = 5{\cdot}3$, $P < 0{\cdot}0001$).

It seems, therefore, that the finding of Angervall is not confined to chickens, but may be a more general phenomenon of the growing process during which a reduction or redistribution of the adipose tissue enzyme may occur and which may involve man as well. Whether this phenomenon is related to the amount of circulating growth hormone and whether the properties of this hormone as regards fat metabolism are due to this possible relationship is an interesting speculation.

Salicylate and Increased Vascular Permeability

We have previously found that high doses of systemically injected salicylate (600 mg/kg) reduce the œdema subsequent to injury in the rat[1] and that in the rat similar systemic doses of salicylate cause a non-specific suppression of the increased vascular permeability following intradermal injections of histamine, 5-hydroxytryptamine (5HT), 'globulin permeability factor' and bradykinin.

In an attempt to detect a more specific action of salicylate which might explain some of the drug's anti-inflammatory effects, salicylate was injected intradermally with various substances that increase capillary permeability. It was found that salicylate in local concentrations of 2·5 mg/ml. caused total suppression of increased vascular permeability as indicated by the accumulation of circulating protein-bound trypan blue[2] at intradermal injection sites following injections of bovine pancreatic kallikrein (Bayer) in concentrations of 1–10 units/ml. It also caused total suppression of the similar action of a sample of human salivary kallikrein (about 5 units/ml.). At 1·0 mg/ml. salicylate had little effect on the leakage of trypan blue due to intradermal injection of these samples of kallikrein. Locally injected salicylate (2·5 mg/ml.) caused a 90 per cent suppression of the dye leakage following intradermal injection of 'globulin permeability factor' prepared by ether/ethanol fractionation of rat serum[3] (Table 1).

Table 1. Effect of Local Concentrations of Salicylate on the Increased Capillary Permeability in the Rat induced by Different Permeability Factors

Concentration of local salicylate (mg)	Permeability factor (P.F.)	Accumulation of trypan blue (μg) (increased permeability)
—	Kallikrein	6·3
2·5	Kallikrein	0
1·0	Kallikrein	6·1
—	Bradykinin	3·5
2·5	Bradykinin	3·8
6·0	Bradykinin	3·0
—	Globulin P.F.	6·1
2·5	Globulin P.F.	1·1
—	P.F. dil.	3·2
2·5	P.F. dil.	3·1
—	Substance *P*	6·0
2·5	Substance *P*	5·9
—	Histamine	5·6
2·5	Histamine	5·4
—	5 HT	6·2
2·5	5 HT	3·2

Salicylate, however, was without demonstrable effect on the increased vascular permeability caused by intradermal injections of synthetic bradykinin (10–100 µg/ml., Sandoz, Ltd.) partially purified ox blood bradykinin (50 µg/ml.) dilute permeability factor prepared by diluting rat serum 1 : 50 – 1 : 100 and standing 1 h before testing or 1 : 10 – 1 : 20 and leaving 14 min before testing[4]. Similarly, salicylate was without effect on the permeability factor formed in rats' plasma after the addition of turpentine[5]. The increased capillary permeability caused by intradermal injections of substance *P* (1–10 units/ml.) was also unaffected by salicylate in local concentrations of 2·5 mg/ml. However, local salicylate in these concentrations caused a 50 per cent suppression of the dye accumulation induced by intradermal injections of 5-hydroxytryptamine (5–20 µg/ml.).

In the guinea pig it was found that salicylate in a local concentration of 2·5 mg/ml. caused a total suppression of the leakage of circulating trypan blue due to the intradermal injection of 1 unit/ml. kallikrein, and a 50 per cent suppression of that due to 2 units/ml of kallikrein. As in the rat these doses of salicylate failed to modify the vascular response due to intradermal bradykinin.

Recently, Northover and Subramanian[6] showed that salicylate and phenylbutazone were effective in preventing the formation of kallidin from guinea pig and ox serum kallidinogen by the action of human salivary kallikrein and guinea pig serum kallikrein. These findings are consistent with the results of the present investigation. Bhoola, Calle and Schacter[7] have previously remarked on the similarity of serum 'globulin permeability factor' to the enzyme kallikrein. The suppression by local salicylate of the vascular effects of these factors is another point of resemblance. The failure of salicylate to inhibit what may be the respective active end products of these two substances, that is, kinins and dilute permeability factor, may also be significant in this regard.

It thus appears there is some support for the view[8] that part of the anti-inflammatory effect of salicylate may be due to the suppression of kallikrein-like enzyme systems which form permeability factors during inflammation. The results suggest also that, at least in the rat, systemic administration of salicylate may have effects which partially mask the more specific actions of the drug, demonstrable when salicylate is injected intradermally with substances which increase vascular permeability.

Uniformity of the Contractile Response of Ventricular Muscle in High-Calcium Tyrode's Solution

Among several conditions related to the sequence and rate of stimulation which affect the contractile response of cardiac muscle, prematurity of an excitation, interposed in a regular sequence, results in a beat of reduced tension or shortening. The weakness of the premature beat is unrelated to factors of electrical excitability, time-course or amplitude of the transmembrane action potential or pre-contractile length of the muscle[1,2]. The possibility that developed tension or shortening may vary with the transient level of intracellular calcium (or calcium-containing 'activator') has been experimentally supported[3,4]. Unlike the various potentiating effects, such as the ascending limb of staircase, post-extrasystolic potentiation and post-stimulation potentiation, however, the weakness of a premature beat does not clearly follow from such a mechanism without additional assumptions which would predict a low intracellular calcium in the time-interval immediately following a contraction. The residual effect of any contraction on the succeeding one has thus been seen as consisting of separate positive (potentiation) and negative (restitution) components with different time courses of decay[5].

The present communication directs attention to the easily achievable variability of the negative inotropic effect and to the fact that an environment sufficiently high in calcium concentration abolishes all such effects, positive or negative. The resulting contractile response is fixed in a manner ordinarily uncharacteristic of heart muscle, being independent of all variations in the sequence and rate of contraction.

Cat papillary muscles or trabeculæ carneæ from the right ventricle were used. An experimental arrangement previously described[6] permitted sustained and moderately uniform electrotonic alteration of the transmembrane potential over a 0·25-mm length of the muscle. Tension development was recorded from this length of muscle and the transmembrane potential time course was recorded push–pull from the end farther from the polarizing electrodes. Composition of the Tyrode's solution was that conventionally used[7], except where indicated.

The developed tension in a very premature beat appears to vary with the phosphate content of the Tyrode medium, amounting to about 10 per cent of that of the driven beat in high (3·2 mM) phosphate and often exceeding 50 per cent of the driven beat tension in low (0·32 mM) phosphate Tyrode. Fig. 1 illustrates another factor, the time-course of the transmembrane potential, which influences the strength of contraction in the period following a driven beat. Two successive exposures are superimposed. The two inside curves are the electrical (depolarization upwards) and mechanical (tension downwards) records of a driven beat (rate 0·4/sec) followed by a premature beat, the action potential upstroke of which falls on the previous repolarization limb. The outer curves demonstrate a fact, previously reported[6], that tension (lowest trace) is maintained at near-peak levels during sustained membrane depolarization (highest trace). At a time when a premature beat delivers only 65 per cent of the driven beat tension, sustained depolarization is associated with a tension amounting to 85 per cent of the initial peak value. The weakness of the premature beat thus appears to depend on some factor associated with either the electrical repolarization process or with relaxation itself.

In a medium of composition equivalent to that of '12-fold calcium' Tyrode (6-fold calcium, 75 per cent sodium, see ref. 8), weakness of a premature beat as well as postextrasystolic potentiation are entirely abolished, as is shown in Fig. 2. The traces at the upper left show a driven beat followed by a stimulus so premature as to evoke only a non-propagated electrical response. When the second stimulus is delivered a bit later (upper right), the premature contraction is not at all reduced and fuses with the driven one. The lower traces show premature responses at progressively greater time intervals after the driven beats. All contractile responses have magnitudes within 5 per cent of the mean. In addition, the traces at the lower left represent events immediately following those on the upper right (driven rate 0·4/sec) and there is no postextrasystolic potentiation following a beat of extreme prematurity.

The contractile response in '12-fold calcium' Tyrode medium also did not vary with rate of stimulation, being fixed at the level shown in Fig. 2 at rates of 0·4/sec, 1/sec, and 6/sec. At the last rate, a contractile time-course close to the maintained tension with prolonged depolarization is obtained. This is shown in Fig. 3, where the electrical and mechanical events associated with continued flow of depolarizing

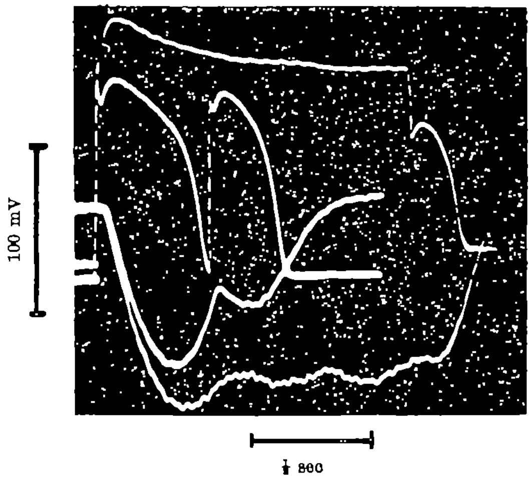

Fig. 1. Superimposed records of. a premature beat following a driven one (inner traces); an electrotonically induced contracture (outer traces). Transmembrane action potentials upward and isometric contractions downward. Action potential upstrokes and initial return from sustained depolarization are drawn in as dashed lines. Tension is of the order of 200 mg. Driven rate 0·4/sec. Normal Tyrode medium

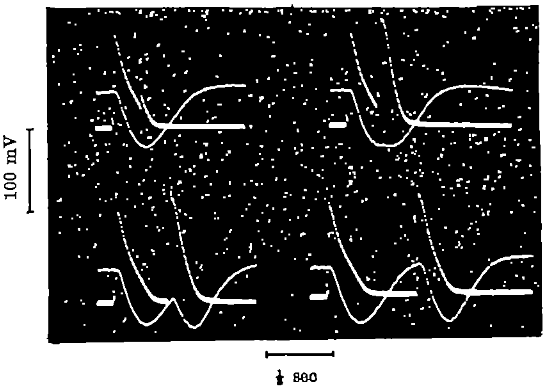

Fig. 2. Four successive driven beats, each followed by a premature stimulus (in the order left to right, lower traces after upper traces). Transmembrane potentials and isometric tensions as in Fig. 1. Peak tension is about 600 mg. Driven rate 0·4/sec. '12-fold calcium' Tyrode medium

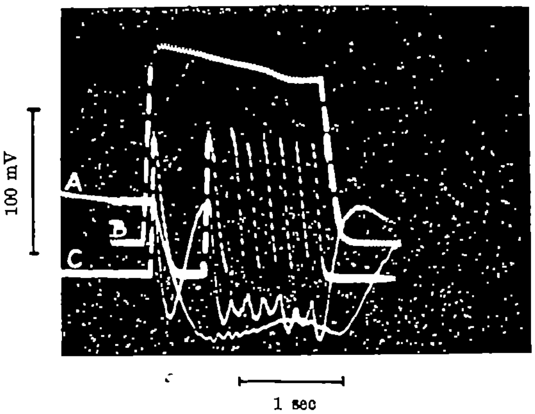

Fig. 3. Superimposed exposures. Upward-going traces display sustained depolarization (*B*) and the last of a series of action potentials at 0·6/sec, followed by a train at 6/sec (*C*). Downward-going traces (*A*) represent the tension time-courses associated with *B* (smooth contracture) and with *C* (incompletely fused contractions). The depolarization and repolarization limbs in *B* and the first two action potential upstrokes in *C* are drawn in as dashed lines. '12-fold calcium' Tyrode medium

current and with rapid repetitive stimulation are superimposed. With the abolition of the negative inotropic effect of a contraction on the succeeding one (restitution), a current contracture due to sustained depolarization is approached by the contractile response evoked by a fast train of action potentials. It may be that the restitution phenomenon is brought about by the release of a substance, governed by repolarization or relaxation, which competitively inhibits subsequent calcium entry into the cell.

PHARMACOLOGY

Quasi-Cholinergic Action of Acetylating Agents

THE process by which acetylcholine causes muscle to contract presumably includes an action of acetylcholine on a definite site. The exact nature of this site, whether it is a small molecule, or a protein or enzyme, or a membrane, is still unknown. Although it is still inexactly defined, this substance or structure has acquired the presumably synonymous names 'cholinergic receptor' and 'acetylcholine receptor'[1,2]. This communication offers evidence that the receptor structure of smooth muscle includes a chemical grouping capable of being acetylated, and that this acetylation process is a part of the chain of events that leads to contraction.

The knowledge that *N*-acetoxytrimethylammonium bromide has an action resembling that of acetylcholine[3] and also that this substance can acetylate several sulphydryl compounds, including glutathione, coenzyme A, and mercaptoethanol, led us to test the effect of dilutions of acetic anhydride on conventional guinea pig ileum preparations[4]. It was found that small concentrations of acetic anhydride caused muscular contraction. Because acetic anhydride reacts with water with a considerable speed, its concentration at the time of contact with the ileum cannot be stated exactly, but the dilutions were made in an ice bath and were used within 1 min of mixing. Under these conditions, contractions were regularly observed at concentrations of 0·17 mg/ml. Measurements of *p*H at the end of each experiment showed only small changes: from 7·5 to 6·5, or in some longer experiments to 6·0. In the presence of atropine, the classical acetylcholine blocking agent, addition of acetic anhydride did not cause contraction. Hexamethonium did not prevent the contraction, a fact that suggests that the action is not upon the ganglia. More extensive experiments were performed with isopropenyl acetate, a more tractable acetylating agent[5]. This substance likewise stimulated the ileum, and was not sufficiently hydrolysed during the experiments to alter the *p*H of the medium. This substance likewise did not cause contraction when atropine was present. It will be recalled that Burgen, Burke and Desbarats-Schonbaum[6] showed that isopropenyl acetate is hydrolysed by cholinesterase faster than is acetylcholine. Tests showed that ileum that had been stimulated by isopropenyl acetate was still responsive to subsequent addition of acetylcholine, *N*-acetoxytrimethylammonium, or to additional portions of isopropenyl acetate. Results with acetylimidazole prepared according to Boyer[5] were, in general, similar. Here again we observed stimulation by the substance, and prevention of stimulation by atropine. Stimulation by acetylimidazole did not prevent subsequent stimulation by acetylcholine.

Table 1. QUASI-CHOLINERGIC ACTION OF ACETYLATING AGENTS

Substance	Stimulatory concentration (mg/ml.)	Concentration of atropine inhibiting (mg/ml.)
Acetic anhydride	0·17	0 00017
Isopropenyl acetate	0·42	0 00017
Acetyl imidazole	0·067	0 00017
N-Acetoxytrimethylammonium bromide	0·001	0 00005
Acetylcholine bromide	0·00002	0·00013

The results are summarized in Table 1. As four of these substances are acetylating agents capable of reacting with sulphydryl groups, the results hint that the receptor site may include a sulphydryl group. This must for the present remain conjectural, since other groups (for example, hydroxy, amino, imidazol) capable of acetylation cannot be excluded.

Enhancement of the Intestinal Absorption of Glucose by Small Doses of Cetrimide and Sodium Lauryl Sulphate

AFTER the growth-promoting activity of aureomycin was discovered in chicks and piglets, some surface-active germicides were tried as feed-additives, and Ely[1] reported a parallel effect with synthetic detergents such as lauryl ethylene oxide. Stern and McGinnis[2] obtained equal growth responses on the addition of vitamin B_{12}, aureomycin or detergent to Ely's basal diets, so that Ely's results were attributed to supplementation of a dietary deficiency in this vitamin, and not to primary growth stimulation. However, claims that related compounds, such as trimethylhexadecyl-ammonium stearate, possessed primary growth stimulating activity persisted. In attempting to clarify the problem during the present investigation, both trimethyl-hexadecylammonium stearate and its corresponding bromide ester, cetrimide, were tested on three-week old and adult albino and *C3H* mice by incorporating the drugs in diet 41 in concentrations ranging from 0·0025 to 0·1 per cent, but no favourable effect on growth was obtained[3,4]. With higher concentrations (0·1–1 per cent), loss of weight was marked, and post-mortem appearances did not differ from those of inanition produced by simple food reduction[5].

In intestinal perfusion experiments, carried out *in vivo* on mice, rats and rabbits, the cationic quaternary ammonium germicides such as cetrimide showed striking inhibitory effects on the absorption of nutrients[6,7]. The anionic sodium lauryl sulphate had weaker inhibitory activity. Furthermore, both potentiated greatly the inhibitory effects of phloridzin on glucose and sodium butyrate absorption[8,9].

When the investigation of the effect of cetrimide by the intestinal perfusion method was extended to low concentrations, the substance showed an enhancing effect on the absorption of glucose, but not of sodium butyrate or methionine. The percentage absorption increased from 35·0 ± 1·0 in the control to 51·3 ± 4·5 at a concentration of 0·0005 per cent of cetrimide ($P < 10^{-5}$). This represents a rise of 46·6 per cent, and is probably close to the peak of the stimulant effect (Table 1 and Fig. 1). Inhibitory activity appeared at higher concentrations. At 0·001 per cent, the percentage absorption was 47·8 ± 2·1, which still differed appreciably from the control ($P < 10^{-10}$), but at a concentration of 0·002 per cent the stimulant effect was almost completely nullified. The number of experiments at each dose-level is given in Table 1.

Sodium lauryl sulphate showed similar stimulating activity at a concentration of 0·001 per cent. The percentage absorption was 51·4 ± 2·8, representing a rise over the control of 46·9 per cent, with *P* value $< 10^{-10}$. Higher concentrations reversed this effect, and significant inhibition was established at 0·1 per cent.

The enhancement of absorption at low concentrations of these drugs is unlikely to be a non-specific effect due to surface-activity of the compounds, for it is absent in the case of sodium butyrate and methionine. An even more pertinent observation is that these same stimulating concentrations of the two compounds produce striking inhibition, with absorption percentages for glucose of 7·0 and 16·5 per cent with cetrimide and sodium lauryl sulphate respectively (4 experiments each), when combined with a concentration of 0·001 per cent of phloridzin. When phloridzin was used by itself at this concentration it had scarcely any effect, giving a percentage absorption of 34·4 per cent for the mean of eight experiments.

Whether these findings provide an alternative explanation for Ely's results is doubtful, for no stimulant effect has been obtained by putting mice on diets containing small concentrations of cetrimide, the stearate ester or sodium lauryl sulphate. The possibility that the stimulant effect is nullified by some food component must, however, be considered. The foregoing findings may prove of value in clinical malabsorption.

Table 1

Drug concentration (%)	Percentage absorption of glucose from perfusion fluid. No. of experiments in parentheses Cetrimide	 Sodium lauryl sulphate
0·0	35·0 ± 1·0 (37)	35·0 ± 1·0 (37)
0·00025	40·9 ± 4·3 (6)	
0·0005	51·3 ± 4·5 (6)	
0·001	47·8 ± 2·1 (20)	51·4 ± 2·8 (11)
0·002	36·1 ± 1·7 (31)	
0·01	25·2 ± 2·0 (14)	34·9 ± 1·9 (6)
0·1	3·7 ± 1·5 (4)	20·8 ± 1·3 (6)

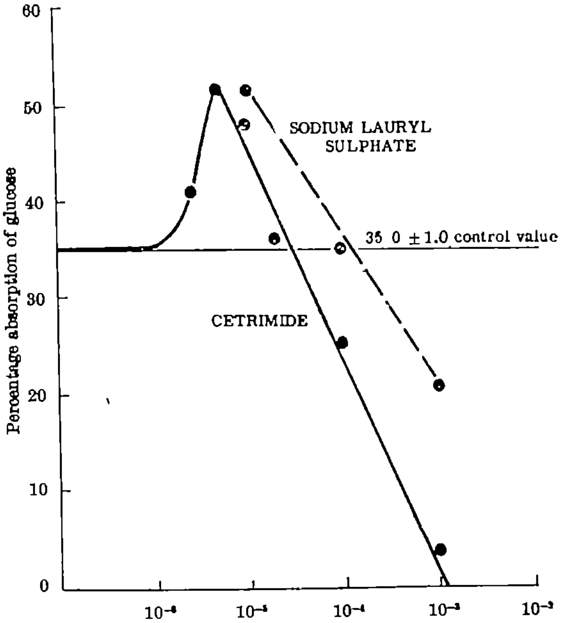

Fig. 1 Percentage absorption of glucose—out of a total of 50 mg in 25 ml. fluid—in ½ h intestinal perfusion experiments in mice. Low concentrations of cetrimide and sodium lauryl sulphate had a stimulant effect and high concentrations an inhibitory effect as compared with the control

The enhancement of glucose absorption in perfusion experiments with cetrimide and sodium lauryl sulphate is also of theoretical interest in view of the rate theory of drug action put forward by Paton[10], according to which antagonists would be expected to possess stimulant activities at low concentrations. The circumstances for which this theory holds remain to be elucidated, but it is interesting that acetylcholine antagonists studied by Paton in his drug-receptor investigations included trimethylalkylammonium compounds.

'Cross-Protection' Method as a Means of Differentiating Receptors

In 1954 Furchgott[1] described a method for determining whether two drugs act on a common receptor. One of his experiments may be used to illustrate this. A spiral strip of rabbit aorta was exposed to 3 × 10^{-6} dibenamine for 20 min either with no other drug in the bath or with 10^{-4} adrenaline present. The tissue was washed after the 20-min exposure and sensitivity to noradrenaline was tested. This was zero when dibenamine had been given alone, but still 20 per cent of normal when adrenaline had been present. It was presumed that the adrenaline occupied an appreciable fraction of the receptors and thereby protected them from combination with dibenamine and consequent blockade. "From results such as these it is concluded that epinephrine, norepinephrine and isopropylarterenol react with the same set of contraction receptors in the aortic smooth muscle."

This method has since re-appeared periodically as a tool for demonstrating that two drugs act on the same receptor. Pharmacologically, however, the basis of the method is not sound. The purpose of this communication is to point this out and demonstrate why. Two pharmacological concepts are involved here. (1) There is no *a priori* reason (as Furchgott himself points out) to suppose that any drug combines with only one site. Usually this appears to be the case in practice since the concentration is kept low so as to produce a pharmacologically effective drug-receptor combination only at the most sensitive site(s). But in the cross-protection method a large dose of the protecting agent is used so it is to be expected that an appreciable occupancy of many sites will result. (2) There is considerable evidence that stimulant drugs can stimulate a tissue markedly when only a small proportion of the receptors involved are free. (Whether this be pictured as 'spare-receptors' or 'spare-receptor capacity'[2] is immaterial here.) Consideration of these two concepts shows that the original conclusion is not unique. As an example let us consider a given receptor pool. We may picture a drug which (in the usual pharmacological concentrations) combines negligibly with it. However, at the much higher doses generally used for protection, this drug might occupy and protect say 5 per cent of receptors. This number of receptors would probably be quite sufficient for the production of a strong effect by a second drug (which is characteristically a strong agonist). Thus two drugs would appear to 'react with the same set of receptors', but the interaction would be of little or no pharmacological or physiological significance.

The converse conclusion, that is, that absence of protection is evidence that the two receptors are different, is also not rigorous. This is especially true if the stimulant drugs behave as Paton[2] has suggested, that is, that their drug-receptor interaction is associated with a high turnover-rate. The blocking agent could then have access to all the receptors even during a relatively short exposure and the degree of protection could be negligible.

The method of 'cross-protection' seems therefore to be rather less useful than is generally recognized.

PATHOLOGY

Effect of Thiouracil on the Development of Mammary Tumours in Rats induced with 9,10-Dimethyl-1,2-Benzanthracene

THE induction of mammary tumours in rats by the oral feeding of a chemical carcinogen has been found to depend on the hormonal state of the animal[1-3]. This communication deals with the attempted production of such mammary tumours by the oral administration of 9,10-dimethyl-1,2-benzanthracene (DMBA) in rats made hypothyroid with propylthiouracil (PTU).

Table 1. SUMMARY OF METHODS AND GROUPS

No. of rats	PTU	DMBA
30	5 mg daily for 95 days	10 mg once/week. Reduced to 5 mg after 4 weeks. Stopped at 95 days
80	None	As above
80	5 mg daily for 95 days	None

Table 2. MAMMARY GLAND TUMOUR INCIDENCE IN RATS GIVEN DMBA AND DMBA + PTU

Days after first administration of DMBA		60	80	100
Rats with tumours	DMBA	10/24	16/22	20/20
	PTU + DMBA	1/22	4/21	7/14
P*		0·003421	0·000503	0·000637

* P was calculated by the method of Yates and Fisher (see *Statistical Methods for Research Workers*, Fisher, R. A., thirteenth ed., 96 (1958)).

Non-inbred rats descended from stock imported from Sprague–Dawley of Madison, Wisconsin, and commercially available in Britain were bought at 40 days of age. After a formal randomization process they were divided into groups for treatment as shown in Table 1.

10 mg DMBA, dissolved in 0·5 ml. corn oil, was given by gastric tube once weekly, the first dose at 50 days of age. 5 mg PTU, suspended in 0·5 ml. of sterilized arachis oil, was given by mouth daily from 50 days of age.

Of the group given PTU + DMBA mammary gland tumours were found in 1 of 22 rats alive at 60 days, 4 of 21 rats at 80 days and in 7 of the surviving 14 rats at 100 days (Table 2). Corresponding figures for DMBA alone were 10 rats with tumours of 24 alive after 60 days, 16 of 22 rats at 80 days and 20 rats with tumours of 20 after 100 days. The difference in the numerical incidence of mammary tumours between rats having DMBA + PTU and rats having DMBA alone is highly significant statistically ($P < 0·01$). Mammary gland tumours were not seen in any rat given only PTU. The mortality of the rats given PTU + DMBA was somewhat higher than that of the rats given only DMBA.

Jull and Huggins[2] showed that after DMBA, fewer rats developed mammary tumours in thyroidectomized animals than in intact controls. Our results indicate that hypothyroidism chemically induced by PTU is capable of producing the same effect. Jull and Huggins have suggested that this might be the result of diminished caloric intake.

Uptake of Proteins by Malignant Cells

A RECENT immunohistochemical investigation of *p*-dimethylaminoazobenzene-induced hepatomas in rats[1] has supported the view that plasma proteins can be taken up by cancer cells without prior extracellular hydrolysis[2]. However, hepatic parenchymal cells after only minor injury are known to be permeable to serum proteins[3]. We have therefore studied by direct and indirect fluorescent tracing methods[4] the uptake of serum proteins in tumours arising in other tissues.

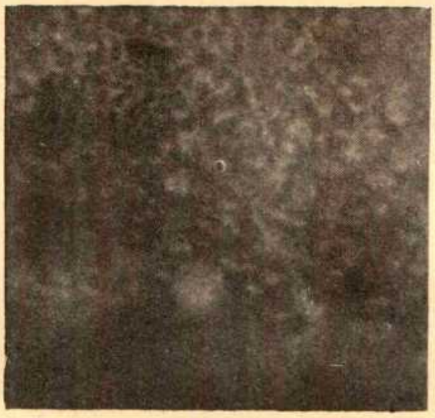

Fig. 1. Frozen section of solid Ehrlich carcinoma taken 3 h after intravenous injection of rabbit serum conjugated with *RB* 200. The fluorescent protein, sometimes distinguishable as droplets, is present in the cytoplasm of the malignant cells above but not in the narrow zone of normal subcutaneous tissue below. (× *c* 80)

The tumours used were primary benzpyrene-induced fibrosarcomas in adult (240 g) Wistar rats, and Ehrlich ascites tumour, Landschutz tumour, *S* 37, and *T* 2146 maintained in the ascites form by serial transplantation in Swiss albino mice (25 g) bred in a closed colony. The ascites tumours were also used in the corresponding solid form obtained by subcutaneous transplantation.

For direct tracing, whole normal rabbit serum conjugated with lissamine rhodamine *B* (*RB* 200) was injected at a concentration of 58 mg protein/ml.: in the rats 2 ml. doses were injected through the jugular vein and in the mice 0·4 ml. through the tail vein. For immunofluorescence tracing, a γ-globulin fraction (separated from normal human serum by passage through DEAE-cellulose using 0·0175 M phosphate buffer at *p*H 6·3) was injected at the same dose and by the same routes.

Animals were killed 1–3 h after the injection, and tissue blocks both from tumour-bearing and normal animals were taken immediately and snap frozen at − 76° C. On the same day, solid tumours and samples of liver, spleen, kidneys, lungs, gonads, adrenals, lymph nodes, muscle and subcutaneous tissue were studied by sectioning at 5μ in a cryostat at −20° C. The ascites tumours were examined as air-dried smears which were treated in the same way as the sections.

In the direct tracing experiments, the sections were fixed in 95 per cent ethanol for 30 sec, rinsed in phosphate-buffered saline (*p*H 7·1) and mounted in buffered glycerol. In the immunofluorescence experiments, the unlabelled human globulin was located in ethanol-fixed sections treated for 30 min with goat anti-human-globulin conjugated with *RB* 200. Tissues from normal and from tumour-bearing animals not injected with human γ-globulin served as controls, and specificity of fluorescent staining was assessed by treating parallel sections with labelled goat anti-rabbit-globulin, which failed to stain, and by the demonstration of blocking of staining in preparations pre-treated with unlabelled anti-human-globulin.

Examination of preparations by fluorescence microscopy showed that the only normal tissues to take up exogenous serum proteins were the Kupffer cells of the liver, and to a lesser extent the phagocytes of spleen and an occasional littoral cell in the adrenal medulla; none was found in the parenchymal cells of any organ. In contrast, the ascites tumour cells as well as the cells of the solid neoplasms showed in the cytoplasm a substantial amount of protein conjugate in the direct tracing experiments (Fig. 1) and of the γ-globulin in the immunofluorescence experiments. There was no detectable conjugate or γ-globulin in the necrotic areas or the stromal cells of the solid tumours. In the cytoplasm of ascites tumour cells the administered proteins were distributed diffusely whereas in the solid tumour they often appeared as droplets. The serum proteins were not found in the nucleus of any cell.

Thus it would appear that the property of direct protein uptake reported in hepatoma cells is shared by malignant cells of other primary and transplanted tumours. This process is distinct from the known capacity of tumour cells and all rapidly growing tissues to sequestrate amino-acids from the common metabolic pool[5], though both phenomena fit Mider's apt description of tumours as nitrogen traps[6]. Whether the protein uptake is attributable to increased permeability of tumour cell membrane[7] or to a more active process remains to be determined.

We thank Prof. A. Haddow, Chester Beatty Research Institute, London, for supplying the Wistar rats with benzpyrene-induced fibrosarcomas. This work was supported by grants from the Medical Research Council and the Scottish Hospital Endowments Research Trust.

Familial Hypothalamic Diabetes Insipidus in Rats

WE are at present raising a strain of rats with hypothalamic, vasopressin-sensitive diabetes insipidus. This disease arose as an apparently spontaneous mutation along with a mutation for albinism in some of the affected animals, from a pure strain of Long-Evans hooded rats being bred for an unrelated research problem not involving radioactivity. The original litter of 17 included 4 albino females with diabetes insipidus, one albino male without diabetes insipidus, and one hooded male and one hooded female each with diabetes insipidus.

Response of one of the diseased female rats to injections of vasopressin tannate in oil ('Pitressin Tannate in Oil', Parke, Davis and Co.) is illustrated in Fig. 1. Each point represents a 24-h collection period, either in the untreated state or from one to five days after a single injection of 0·5 pressor unit. The graph is a composite of several experiments and represents the response to progressively diminishing blood titres of vasopressin. During the period of these tests the mean weight of this rat was 260 g, and the mean water intake in the untreated state was 105 g water/100 g

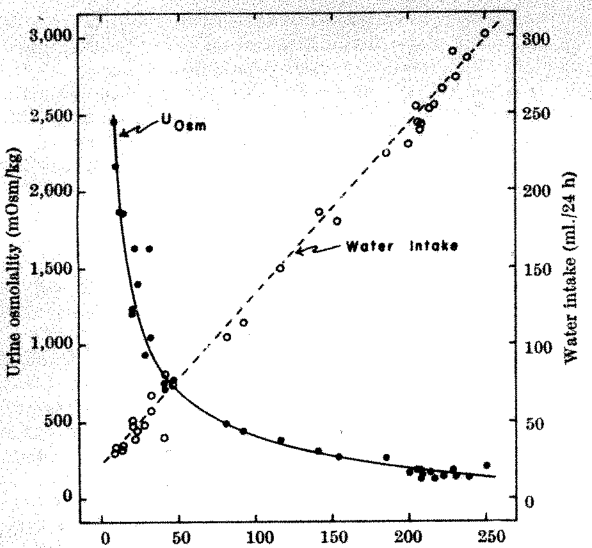

Fig. 1. Urine flow, urine osmolality and tap water intake of a single rat with familial hypothalamic diabetes insipidus, both untreated and after subcutaneous injections of vasopressin tannate in oil

body-weight/24 h, as compared with 14 g water/100 g body-weight/24 h of control female rats. While 6 h of dehydration in this rat caused reduction in urine flow of about 50 per cent, urine osmolalities did not rise above 250 mOsm/kg. These periods of dehydration were accompanied by a mean weight loss of 19 g or 7·5 per cent of body-weight. The urine was negative for reducing substances, and the rats had a normal non-fasting blood glucose concentration of 103 mg per cent. The pars nervosa of the pituitary gland of this rat showed a reduction in neurosecretory material to about one-third of normal, when stained by the aldehyde fuchsin method. Other physiological, anatomical and pathological studies are under way.

Although the disease has been carried into the *F*2 generation, the mode of inheritance is not yet fully defined. There is a high degree of semi-sterility, especially in the males, and a high incidence of still-births and runts. Thus far all the diseased animals in the *F*1 and *F*2 generations are hooded; of these 9 are males and 12 are females. In contrast to the disease in man[1,2], the diabetes insipidus in our rats is inherited neither as a simple dominant nor as a sex-linked trait. Albinism without co-existent diabetes insipidus also has been carried into the *F*2 generation, and is inherited as an autosomal recessive.

So far as we can determine, familial hypothalamic diabetes insipidus has not been reported in a common laboratory animal. In the mice described by Silverstein *et al.*[3] excessive thirst appears to be the primary defect, whereas in our animals the water deprivation test and histological picture indicate that some defect in production of anti-diuretic hormone is primary.

IMMUNOLOGY

Prevention of Delayed Foreign Marrow Reaction in Lethally Irradiated Mice by Early Administration of Methotrexate

A MORTAL wasting disease occurs in lethally irradiated mice which have been engrafted with allogeneic marrow that is capable of reaction against host tissue antigens. The disease appears late, usually several weeks after exposure to radiation. Two components have been described: an early injury to the host, particularly to the lymphoid areas, by immunologically competent lymphoid cells contained in the marrow injection; and a delay in the restoration of the host's lymphoid centres which increases mortality by leaving the host vulnerable to infection and intercurrent disease over a prolonged period[1].

One puzzle has been why the immunologically competent cells of the foreign marrow are not 'paralysed' in the presence of excess host tissue antigen. If time is required and if the critical injury to the host occurs in the first few days, before tolerance or paralysis develops, it might be expected that the restraining action of methotrexate on immunological response[2] and foreign marrow reaction[3] would be most efficacious if administered promptly.

Table 1. EFFECT OF VARIED SCHEDULES AND DOSES OF METHOTREXATE ADMINISTRATION ON MORTALITY FROM FOREIGN MARROW REACTION IN IRRADIATED *BDF*$_1$ (*C57B*1/6*J* × *DBA*/2*J*) MICE INJECTED WITH PARENTAL *C*57 BLACK MARROW

Group	Treatment	Survivors on post-irradiation days		
		10	30	90
1	850 r. (250 kV, X-ray)	6/10	0/10	0/10
2	850 r. + *BDF*$_1$ marrow	10/10	10/10	10/10
3	850 r. + *C57B*1 marrow	9/10	6/10	1/10
4	850 r. + *C57B*1 marrow. Methotrexate 1·5 mg/kg intraperitoneally on post-radiation day 1, 3, 6 and 8	10/10	10/10	10/10
5	850 r. + *C57B*1 marrow. Methotrexate 1·5 mg/kg intraperitoneally three times weekly for 5 weeks beginning on day 1	9/10	7/10	5/10
6	850 r. + *C57B*1 marrow. Methotrexate 0·25 mg/kg intraperitoneally three times weekly for 5 weeks beginning on day 1	10/10	10/10	9/10
7	850 r. + *C57B*1 marrow. Methotrexate 1·5 mg/kg intraperitoneally three times weekly for two weeks beginning on day 14	9/10	2/10	1/10

* Irradiated mice were randomly divided into experimental groups as listed. Each mouse received 16–24 × 10^6 nucleated marrow cells intravenously on the day of radiation. Experiments comprising Groups 1, 2, 3 and 4; Groups 1, 2, 3 and 5; and Groups 1, 2, 3 and 7 were done on three occasions with results similar to those presented. Long-term survivors of Group 4 had hæmoglobin with the electrophoretic mobility of *C*57 black.

As shown in Table 1 this is the case. When methotrexate is administered beginning on the day following the infusion of marrow (Group 4), no mortal wasting disease, no loss of weight beyond that seen in controls given isogeneic marrow, occurs in irradiated *BDF*$_1$ mice injected with parental *C*57 black marrow. When the injections of drug are prolonged, loss of weight and death from drug toxicity are seen (Group 5); unless a lower dose is used (Group 6). When the injections are started late (day 14) the effectiveness of the treatment is less and an appreciable mortality occurs (Group 7). It is striking that the animals treated early and briefly with drug never become ill and wasting is prevented; whereas with those treated late, survival is a matter of recovery from a period of serious wasting.

The observations suggest that if the reaction of immunologically competent cells in the marrow infusion can be restrained during a short interval, either these cells pass through their life-span and die without injuring the host, or they and their progeny acquire tolerance to their environment without first having injured it and themselves by reaction.

Immunological Investigation of a Christmas Factor Inhibitor by Means of Boyden's Technique

THE question whether the circulating anticoagulants are antibodies is still unsettled. An attempt was made to examine the Christmas factor inhibitor (factor IX inhibitor, or P.T.C. [plasma thromboplastin component] inhibitor) using an immunological method. The method of passive hæmagglutination, or Boyden's technique[1], was chosen because it is one of the most sensitive immunological techniques.

The antigen used was the P.P.B. (prothrombin, proconventin, antihæmophilic factor B) or the C.S.B. (convertin, Stuart factor antihæmophilic factor B) fraction prepared at the Coagulation Laboratory of the National Blood Transfusion Centre in Paris, according to a method improved by Didisheim, Loeb, Blatrix and Soulier[2].

The P.P.B. fraction is prepared from human plasma. It contains: prothrombin, proconvertin, the Stuart factor and the Christmas factor. These factors are extracted by adsorption on tricalcium phosphate. After washing they are eluted out by trisodium citrate at *p*H 8. Two successive ethanol precipitations allow a more extensive purification.

The C.S.B. fraction is prepared by the same method from human serum where prothrombin is consumed. It therefore contains only convertin, the Stuart factor and the Christmas factor.

These two fractions were used interchangeably in this investigation with identical results.

74 sera were tested against this antigen (Table 1).

Table 1. RESULTS OF BOYDEN'S TEST ON 74 SUBJECTS. ERYTHROCYTES TREATED WITH TANNIC ACID AND COATED WITH THE C.S.B. FRACTION

No. of cases	Diagnosis	Test for anticoagulant	Boyden's test
3	Christmas disease	Positive: Christmas factor inhibitor	Positive*
10	Christmas disease	Negative	Negative
4	AHG deficiency	Positive: against AHG:	Negative
13	AHG deficiency	Negative	Negative
1	Hæmorrhagic syndrome with acquired anti-coagulant	Positive: against AHG	Negative
1	Stuart factor deficiency	Negative	Negative
3	Thrombocytopænic purpura	Positive: against thromboplastin	Negative
1	Pan hæmocytopænia	Positive: against thromboplastin	Positive†
1	Myeloma	Positive: against thrombin	Negative
14	Multiple transfused patients with various blood disorders	Negative	Negative
23	Normal subject	Negative	Negative
Total 74			

* Titres were, respectively: 1 : 320; ⩾ 1 : 1,280; ⩾ 1 : 160.
† Titre, 1 : 20.

(1) 3 sera obtained from patients with Christmas disease (factor IX deficiency) and circulating anticoagulant active against Christmas factor.

(2) 71 control sera: Christmas disease without circulating anticoagulant (10 cases), antihæmophilic globulin (AHG) deficiency with (4 cases) and without (13 cases) circulating anticoagulants (AHG inhibitor), various hæmorrhagic disorders with circulating anti-coagulants active against AHG, exogenous thromboplastin, and thrombin (7 cases), multiple transfused patients (14 cases), normal subjects (23 subjects).

Boyden's test was strongly positive with the 3 first sera and negative with 70 of the 71 control sera. One test was unexpectedly weakly positive. It concerned a panhæmocytopænic patient. The serum contained a circulating anticoagulant of the antithromboplastic type. The serum was kept frozen for two years before being used. The tests made in 1959 showed an antithromboplastin activity. The inhibition tests of the AHG and the Christmas factor had not been performed at that time. They were negative in 1961 with the preserved serum. These results constitute, therefore, a discrepancy between the coagulation tests and the immunological test. Various hypotheses may be given to explain this discrepancy:

(1) The lack of specificity of the immunological reaction appears improbable since all the other tests gave satisfactory results.

(2) The C.S.B. fraction used as antigen could contain traces of thromboplastin. This hypothesis is contradicted by theoretical impossibility and by the fact that other anticoagulants of the antithromboplastin type gave negative results.

(3) The serum from this patient could contain a Christmas factor inhibitor, not detected by the coagulation tests, which may be less sensitive than the immunological tests.

This unexplained case does not seem to invalidate the technique used here, which showed itself in all other cases specific and reproducible.

A neutralization test of the Christmas factor inhibitor by the C.S.B. fraction was carried out. Both the anticoagulant activity and the hæmagglutination activity were inhibited by the C.S.B. The inhibition of the agglutination is analogous to the neutralization of an antibody by its antigen.

The serum obtained from a patient with Christmas disease, and containing an anticoagulant, was fractionated. The anticoagulant activity was tested by the thrombo-elastographic (TEG) method. The anti-coagulant activity was measured by the lengthening of the interval '*r*' on the TEG of normal plasma rich in platelets after contact with the various fractions from serum containing the anticoagulant. This lengthening was compared with that induced by the analogous fractions obtained from a normal serum. These fractions were simultaneously tested by Boyden's technique. Both the hæmagglutination activity and the anticoagulant activity are located in the γ-globulin fraction. The α-β-globulin fraction shows a weak activity, due perhaps to an incomplete separation of the fractions.

These results support the hypothesis that the anticoagulant and the agglutinating substance are identical.

Very substantial arguments may therefore be brought forth in favour of the hypothesis which states that this Christmas factor inhibitor is an antibody:

(1) Boyden's reaction is positive when one uses the Christmas factor as the antigen.

(2) The serum-like substance taking part in Boyden's reaction as well as in the coagulation test is a γ-globulin.

(3) It is neutralized by the Christmas factor in the same manner as that in which an antibody is neutralized by its antigen.

BIOLOGY

Conjugate Spermatozoa of the North American Opossum

IN 1887 Emil Selenka[1] published a monograph describing the reproductive processes, and the embryology, of the North American opossum (*Didelphys marsupialis* L.). One of the many observations made on a colony of these animals, which Selenka maintained in Erlangen, Germany, was that the semen, recovered from the vagina of females shortly after coitus, contained many spermatozoa which swam in closely coupled pairs. Selenka referred to these paired cells as "copulating" spermatozoa, and the drawings which he published showed clearly that these paired spermatozoa are associated in a specifically oriented manner. In 1902, von Korph[2] showed that the paired spermatozoa occurred in the epididymis, but not in the testes. This observation was confirmed later by Retzius[3], Jordan[4], and finally by Duesberg[5] in 1920. Since that time the phenomenon has been briefly referred to only by Wilson[6], in 1928, who recommended the phrase 'conjugate spermatozoa' instead of 'copulating spermatozoa', and by McGrady[7] in 1938. In the past quarter of a century the phenomenon has been ignored, and is a notable omission from contemporary reviews on spermatozoa.

The purpose of this communication is to emphasize the fact, not appreciated hitherto, that conjugate spermatozoa are a normal occurrence in *D. marsupialis*, and to direct attention to a phenomenon which has many features of interest to cell biologists.

Since the beginning of January 1961 we have collected genital tracts from many male opossums live-trapped in south-eastern Pennsylvania.

The testes and epididymides of most of these individuals were fixed in Bouin's fixative shortly after death, but in a few cases spermatozoa were expressed from the epididymis and examined in the living state. To date, 59 male opossums containing epididymal sperm have been examined, and double spermatozoa have been observed in 55 of these individuals. One of the four specimens not containing conjugated spermatozoa was dead several hours before autopsy, and therefore the spermatozoa may have separated during this time; however, we noticed nothing unusual about the other three specimens.

Fig. 1 is a high-power photograph of a section of the contents of the epididymis, showing the heads of several conjugated spermatozoa. In the majority of specimens it is easy to find cross-sections of epididymides, containing considerable numbers of these paired cells. However, it is impossible at the present time to estimate the proportion of spermatozoa that are linked in pairs, since any mechanical manipulation of the epididymis is likely to separate them.

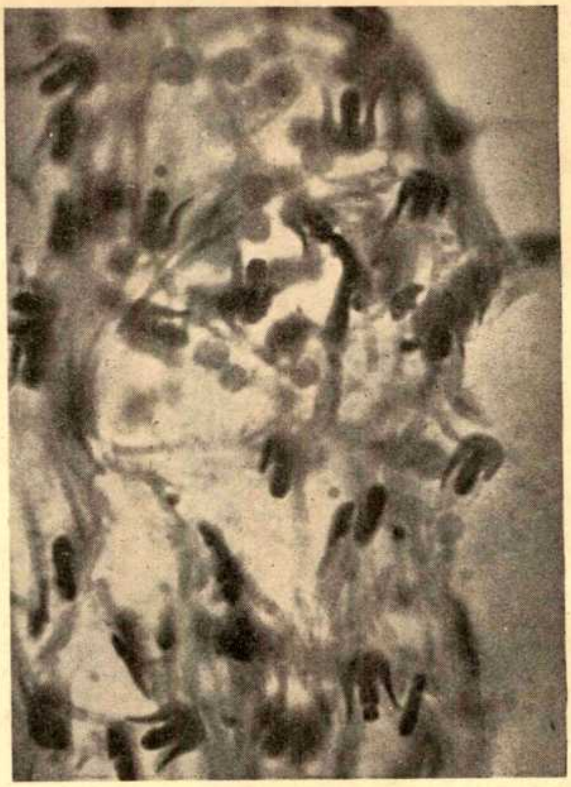

Fig. 1. Section of the contents of the epididymis of an opossum, showing several conjugated spermatozoa. (× *c*. 2,330)

The single spermatozoon of *Didelphys* is illustrated in Fig. 2. Its predominant peculiarity is the hook-shaped head, with one thickened portion and one longer more-pointed portion. The mid-piece of the cell is attached by a very fine filament to the centre of the concavity formed by the long and short portions. Fig. 3 shows two conjugated spermatozoa. All pairs unite by the exact juxtaposition of the shorter portions of the two heads, so that the combined bicellular structure is bilaterally symmetrical about the line of junction. We have examined many hundreds of these pairs of epididymal spermatozoa, and all of them are exactly aligned with this highly specific orientation.

Several of the early workers noted that these conjugate spermatozoa do not occur in the testes. We can fully confirm this fact, in that no conjugate spermatozoa have been seen in any sections of the testes. However, in smears prepared from two testes after tryptic digestion occasional pairs have been seen. It is possible that these may have been derived from the rete testis. Thus it seems that, in the North American opossum, the mature spermatozoa are liberated in the seminiferous tubules as single cells, and that somewhere between these tubules and the epididymis many of them link up in conjugated pairs. How this highly oriented linkage, which is quite distinct morphologically from head agglutination, comes about is a challenge for those cell biologists interested in problems of cell adhesion.

In six cases we have expressed the fresh spermatozoa from the epididymis into a physiological saline

(PBS). This causes a typical activation phenomenon in which all the cells swim violently. However, even under these conditions the conjugate spermatozoa remain paired, swim very powerfully, and describe a linear course of movement. This is in striking contrast to the circular course described by the single cells. Thus the motion of the double and single epididymal cells which we have observed is very similar to the motion of the double and single cells recovered from the vagina of female opossums by Selenka[1]. The mechanics of the motion of the conjugated pairs of spermatozoa has not yet been examined, and seems to pose a fascinating problem to those interested in the kinetics of movement by flagellated cells.

The linkage between the paired cells is strong, but does not involve cellular fusion. This can be easily observed in cells under adverse conditions. We have observed many pairs where one flagellum becomes anchored to the microscope slide. The remaining free flagellum may beat violently, but never strongly enough to free its head from the immobilized partner. Nevertheless, as the cells become exhausted the union between the two heads loosens, until the short portions of the heads of each cell are able to rock on each other. This phenomenon, which proves that cell membranes do not fuse, eventually results in separation of the conjugated cells just before the motility of both cells ceases.

The purpose of conjugated spermatozoa is still obscure. Selenka's early observations show that the pairs enter the female opossum at ejaculation. Whether the conjugation is essential for the ascent of the spermatozoa up the curious lateral vaginal canals of the female opossum is still unknown. What does seem clear is that more positive movement is carried out by the conjugated pairs than by single spermatozoa. If conjugation is a necessity for bringing spermatozoa and ova together, the events immediately prior to fertilization and fertilization itself may be of unusual interest.

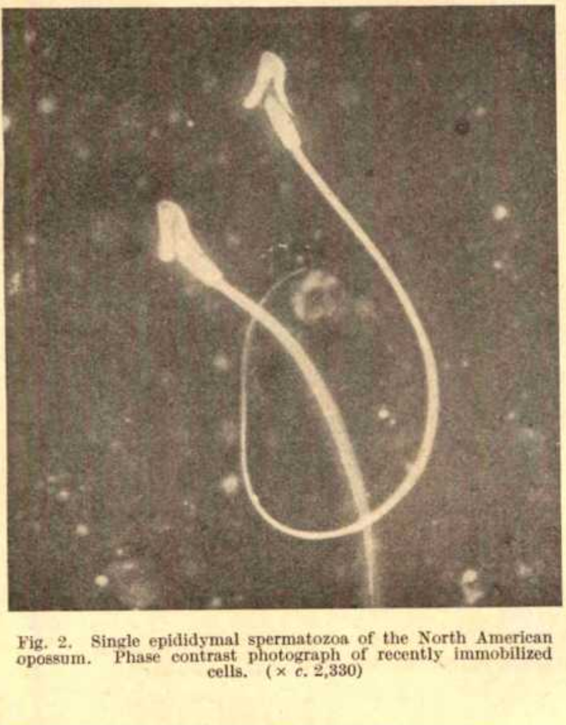

Fig. 2. Single epididymal spermatozoa of the North American opossum. Phase contrast photograph of recently immobilized cells. (× c. 2,330)

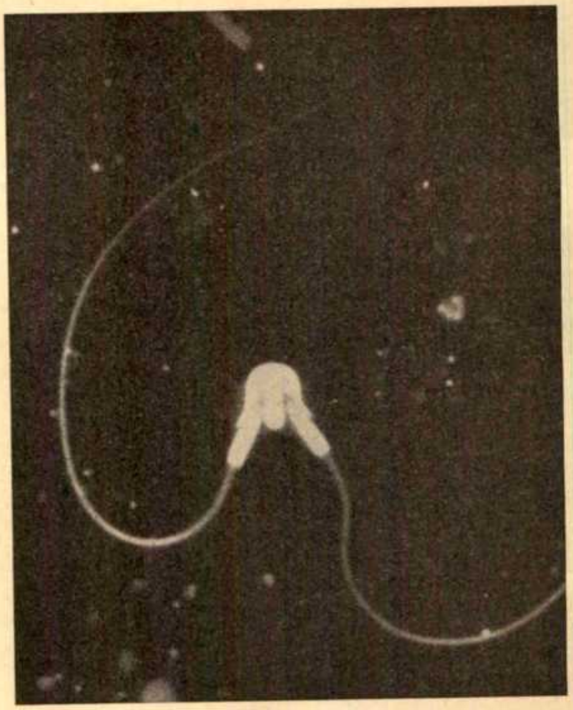

Fig. 3. Conjugated pair of spermatozoa obtained from the epididymis of the North American opossum. Phase contrast photograph of recently immobilized cells. (× c. 2,330)

The uniqueness, or otherwise, of conjugation between pairs of spermatozoa is of particular interest. To the best of our knowledge no adequate study has been made on the spermatozoa of Central and South American opossums, or on those of the Australasian marsupials other than that on the brush-tail possum (*Phalangista vulpiana*) by von Korph[2], who states that conjugate spermatozoa do not occur.

The phenomenon may not be unique, since very similar conjugate spermatozoa have been described in the water beetle (*Dytiscus marginalis* L.)[8] and the gastropod mollusc (*Turritella terebra* L.)[9]. Further investigations are required in the latter two cases, for it seems that at least in *Dytiscus* more than two cells can be involved in the linkage.

The work was supported by grants from the Lalor Foundation and the National Science Foundation (No. *G*17658). One of us (R. F. S. C.) also wishes to acknowledge a Fulbright travel fellowship.

Structure of the Sucker of *Echeneis*

A CENTURY ago Gunther[1] stated thus: "There is scarcely a fish of the existence of which the ancients have been equally certain and which has so much occupied their imagination—from a power thought to be inherent in the creature to counteract the strongest physical agencies—as the *Echeneis* of the Greeks or the *Remora* of the Latins". This was followed in 1918 by Gudger[2], who called it "The most interesting of the marine fishes not merely from the popular but even more from the scientific point of view". He, however, could not reconcile himself to the view that the fish could exert enormous pressure, and accepting Ekman's "deadwater theory" said "Another myth of the ancients is dissipated in thin air". Norman[3] describes the sucker as being a highly specialized structure but goes no further. I have directed attention[4] to the presence of a pear-shaped body, the pyriboss, and a chamber in front of it, and the possibility that the plates are lowered rather than raised adhering. Mention is made of the pyriboss as "a curious round ossification" and the chamber as "a notch at the posterior extremity" by Storms[5].

Fig. 1, I, shows the following parts of the pumping mechanism: (1) The basal plate of the hind region specially enlarged, flattened and directed backwards called the basiplatt. (2) A very small oval or polygonal plate in the middle line immediately behind the basiplatt called the basilid because it is a covering placed over an opening. (3) Then comes an arch which is partly overlapped by the two pieces mentioned already. (4) The front end of the basiarch is prolonged into a process running below the basilid and capable of tipping it open when required. (5) The hind prongs of the arch are partly covered over by the pyriboss. The basiarch has two acute projections pointing forwards from the hind end which have a very important function to perform in pumping. (6) The pyriboss itself has an opening in front, a pair of grooves to accommodate the hind tips of the arch and a second pair of grooves which though unaccommodated must have something to do with the pumping.

Fig. 1, II, shows all the parts when they are separated and further details became visible. In a dead specimen the skin covering the hind region has a double set of muscles symmetrically placed which pass downwards, pass through the gap between the basiarch and the pyriboss and are attached to the basiarch on its underside. The nerve supply to these muscles is clearly visible. Contractions of these muscles will lower the plates and increase the volume of the chamber. The pyriboss is flat dorsally and rounded ventrally. It is attached by elastic tissue passing forward between the vertical muscles just described to the basiarch. There are also strong muscles inserted in tubular grooves in the pyriboss in front and the hind part of the marginal flap behind. These by their contractions can separate the pyriboss from its attachments to the prongs of the basiarch and the elastic tissue in front will now draw it forward at a lower plane. The result will be that it will now occupy the gap in the basiarch and the acute prominences in it will fit into the hind pair of grooves which were not in use before. This is shown in Fig. 1, III. After taking up the new position the pyriboss moves up and down as though hinged. It can open only downwards as the lower surface of the body is broader and so cannot allow it to open the other way.

In Fig. 1, IV, the basilid, which is capable of being raised from behind, is shown attached by two sets of strong muscles which are inserted into openings in the lid and frayed out into grooves in relation with them. The other ends of the muscles pass through the opening to the underside of the basiplatt. They help to keep the lid tightly closed. There are also two other sets of paired muscles which are attached in front below the hind margin of the lids and behind to the groove between the basiplatt and the basiarch. This arrangement means it is a valve which opens upwards and so any fluid can be admitted from the chamber below the basal plates but nothing can get in. It must, however, be noted that the prominence in front of the arch can tip the lid open if it comes in contact with it. This is rendered more probable by a deep cleft in the front margin of the lid intended to accommodate the tip.

A full understanding of the working can be obtained only by observing live specimens in action. This will be undertaken, but the construction of the various parts leaves no doubt that any explanation of the sucking mechanism without taking the parts now explained into consideration must of necessity be defective. A new orientation of our views on the

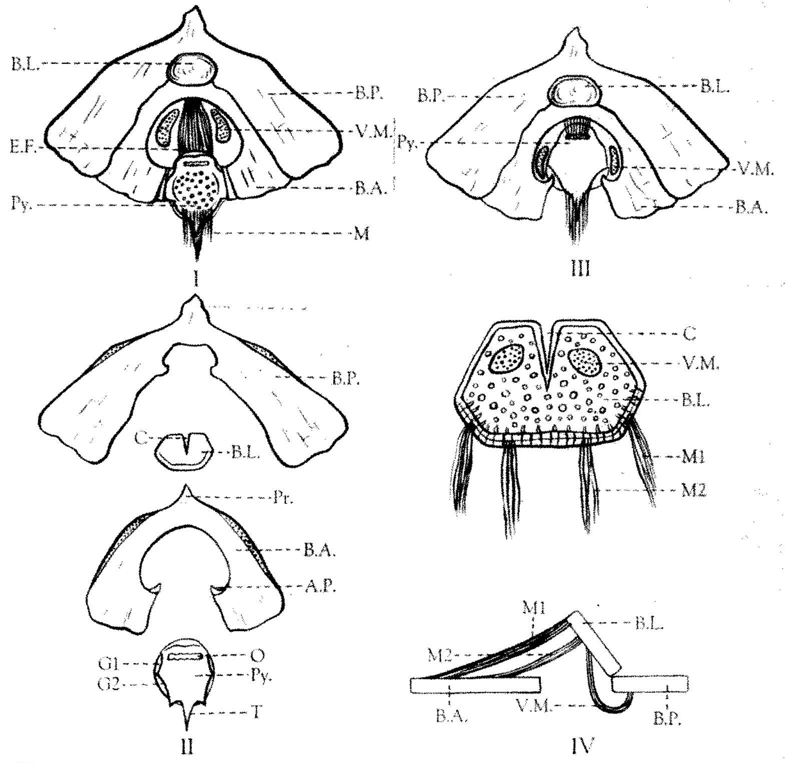

Fig. 1. I, Parts of the hind region of the sucker; II, the parts isolated; III, probable position of the pyriboss while at work; IV, the basilid (dorsal and diagrammatic side-view). *A.P.*, Acute process; *B.A.*, basiarch; *B.L.*, basilid; *B.P.*, basiplatt; *C*, cleft; *E.F.*, elastic fibres; *G* 1 and 2, grooves; *M*, M_1 and M_2, muscles; *O*, opening in the pyriboss; *Pr.*, process to tip open basilid; *Py.*, pyriboss; *T*, tail; *V.M.*, vertical muscles

working of the sucker is inevitable. The possibility of the sucker being a hydraulic structure cannot be ignored.

I thank Alhaj Moulana, S. A. W. Bukhari Sahib, principal, New College, Madras 14, and the management, for permitting me, after my retirement, to continue this work in the College laboratory.

Determination of Certain Phosphate Compounds in Plant Extracts

Except when isotopes have been used, the investigation of the metabolism of the sugar phosphates and related compounds in animal and plant tissues has long been restricted by a lack of specific methods of determination[1]. Recently, however, specific enzymatic techniques have been developed for the estimation of both sugar phosphates and glycolytic intermediates in extracts from animal and plant tissues[2–7]. The enzymatic methods present greater difficulties with plant than with animal extracts, partly because the contents of phosphate compounds are smaller, and partly because the presence of pigments and inhibitors interferes with the assays. But successful results have now been obtained with extracts of potato tubers, strawberry leaves and fruits of banana, tomato and apple.

Using the technique of Isherwood and Barrett[8], the tissue is extracted in trichloroacetic acid and this acid is removed. In some cases (for example, potato) glucose and fructose-6-phosphates can then be determined in the neutralized extract without further treatment. In general, however, after concentration *in vacuo* below 30° C, the extract is cleared with activated charcoal (Harington; 0·4–2·5 g charcoal/10 g plant tissue; two or more treatments as required) to remove pigments and inhibitors. Glucose and fructose-6-phosphates, fructose diphosphate, dihydroxyacetonephosphate, 3-phosphoglycerate and phosphoenolpyruvate were then determined by following the changes in optical density due to reduction of oxidized or oxidation of reduced pyridine nucleotides; these changes were measured either with a spectrophotometer or, for other components, such as fructose diphosphate, the content of which was usually low, a fluorimeter (ref. 9; an E.I.L. fluorimeter was used; three other makes of fluorimeter proved unsatisfactory for the purpose). With potato and banana, but not with strawberry leaf extracts, a further purification treatment was necessary to remove interfering material before using the fluorimeter.

Table 1 gives the contents of various phosphate compounds in certain plant tissues. In bananas a correlation was observed between the changes in the rate of respiration during ripening and the content of fructose diphosphate[10].

Table 1. Content of Certain Phosphate Compounds in Some Higher Plant Tissues as µmoles/100 g Fresh Weight

	Potato tuber (mature)	Strawberry leaf	Banana fruit (green)	Tomato fruit (green)	Apple fruit (immature)
Glucose-6-phosphate	7·0–16·0	16·0–19·0	7·0	8·0	8·0
Fructose-6-phosphate	1·0–3·0	2·0–4·0	1·5	1·5	1·0
Fructose-1,6-diphosphate	0·02–0·04	0·3–0·4	0·05	0·03	0·11–0·17
Dihydroxyacetonephosphate	0·1–0·2	0·5–0·6	0·6–0·7	—	0·2–0·4
3-Phosphoglycerate	2·0–3·0	—	—	—	0·8–1·4
Phosphoenolpyruvate	1·0–1·7	2·5–3·0	1·0	1·5–2·0	0·5–1·0

Dependence of Length of Leaf Lamina on Length of Leaf Sheath in the Rice Plant

In 1960, I reported that water-logging reduced the size of the leaf lamina in upland rice variety Kindinga and that no such reduction occurred in swamp rice variety Dima, when grown under the same soil conditions. If the length of a leaf lamina depends on the length of its leaf sheath a reduction in the length of the latter will also lead to a consequent reduction in the length of the former. If this proposition holds true, the reduction in size of leaf lamina in upland rice variety due to water-logging can, therefore, be attributed to its similar effect on the length of the leaf sheath especially as the width of leaf lamina is not increased by this condition.

For this investigation twenty-four plants of upland rice variety, Agbede, and swamp rice variety, *BG*.79, were raised in pots, each pot containing one plant. Half this number of plants in each variety were grown under water-logged condition and the other half under 'dry' soil (about 75 per cent saturation) condition. Twenty-five leaves of different sizes and ages were selected at random from each group of plants in each variety and the lengths of their leaf laminæ and leaf sheaths measured. From the results obtained the regression line for each variety was drawn.

The lengths of the leaf sheath of the 5th, 6th, 7th, 8th, and 9th leaf of the main shoot of plants grown in water-logged and 'dry' soil conditions in each variety were also measured. Figs. 1 and 2 show that there is a linear relationship between the length of leaf sheath and that of leaf lamina in both upland and swamp

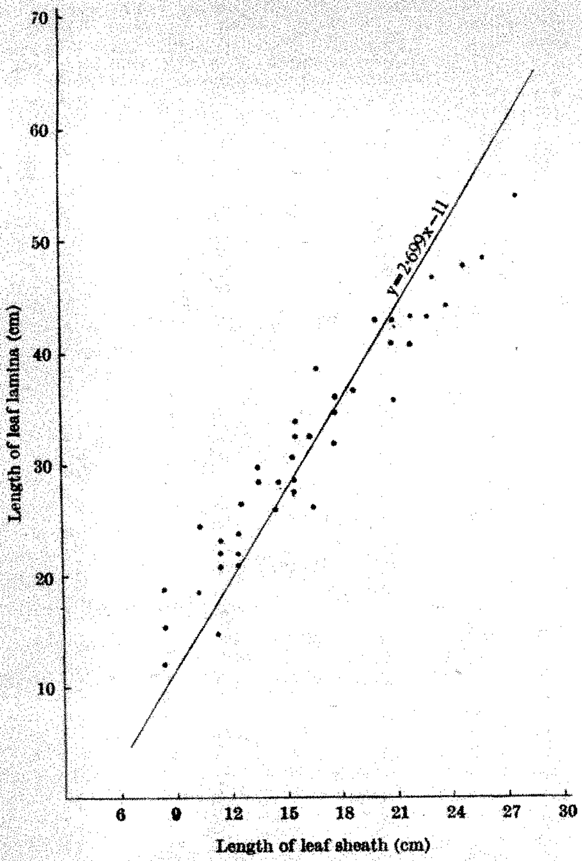

Fig. 1. Regression of length of leaf lamina (y) and of leaf sheath (x) in upland rice variety Agbede (γ = 1·0)

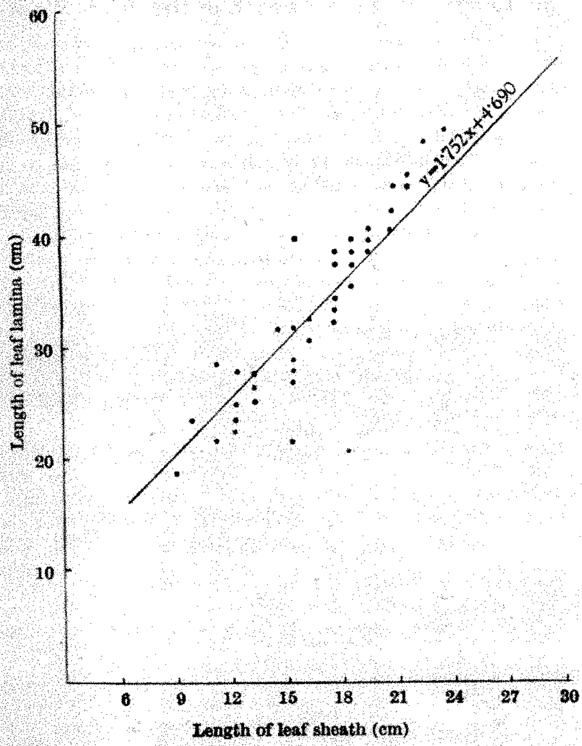

Fig. 2. Regression of length of leaf lamina (y) against length of leaf sheath (x) in swamp rice variety *BG*.79 (γ = 0·98)

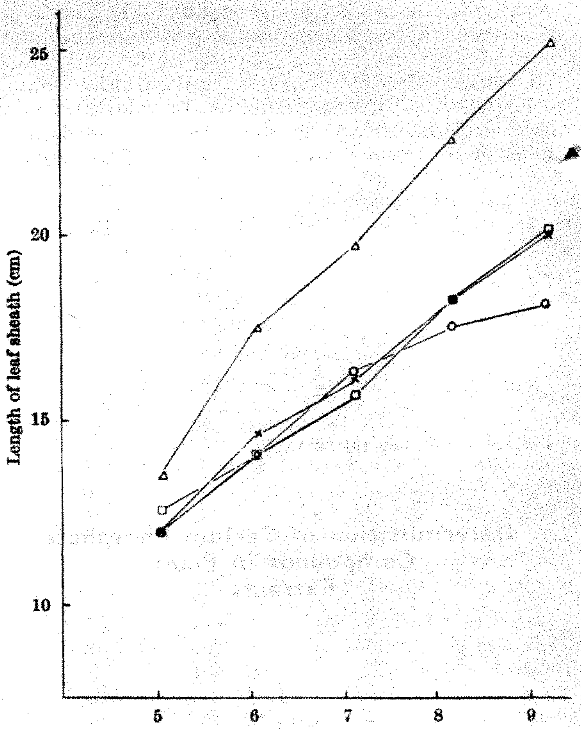

Fig. 3. Effect of soil conditions on length of leaf sheath in swamp and upland varieties of rice. (△) Dry-soil plants and (⊙) water-logged plants of upland variety. (×) Dry-soil plants and (□) water-logged plants of swamp variety

rice varieties used in this study. The correlation coefficients are 1·0 and 0·98 for upland and swamp rice variety respectively, showing, therefore, that there is a complete and a highly positive association between the length of leaf lamina and length of leaf sheath in upland and swamp rice variety respectively.

Fig. 3 shows that there is little or no difference in the length of leaf sheath of swamp rice grown under water-logged and 'dry' soil conditions, but in the upland rice variety water-logging reduced considerably and significantly the length of the leaf sheath.

As it has been established in this work that there is a linear relationship between the length of leaf sheath and that of the leaf lamina in both varieties of rice, a reduction in the length of the leaf sheath in upland rice variety that was brought about by water-logged condition would be expected to lead to a consequent decrease in the length of leaf lamina and therefore to a decrease in its size. In the swamp rice variety no such reduction in the length of leaf sheath of plants grown under water-logged conditions occurred; consequently there should be no difference in the length of leaf lamina and therefore in the size of leaf lamina of dry and water-logged plants.

The presence and absence of such difference in upland and swamp rice varieties respectively between the size of leaf lamina of 'dry' and water-logged plants reported by me[1] can be explained by the findings reported in this communication. It is difficult, however, to explain, at the present time, the cause of the reduction in the length of leaf sheath of upland rice variety grown under water-logged soil.

Effect of Halogenated Benzoic Acids on *Elodea densa*

A WIDE variety of plants have been treated with halogenated benzoic acids since the effect of these compounds as plant growth regulators was first reported by Zimmerman and Hitchcock[1]. A search of the literature has revealed no information on the effects of such compounds on aquatic plants. Accordingly, an experiment was set up to discover the effect of halogenated benzoic acids on *Elodea densa*.

Sprigs of *E. densa* were collected from a local pond. Terminal shoots 25 cm long were examined with a low-power (×40) dissecting microscope. All shoots showing buds or roots were discarded. Each remaining shoot was placed in a 3·1. glass jar containing a litre of tap water and 250 g of washed sand. The appropriate iodo-, bromo-, or chloro-benzoic acids substituted in the *ortho*-, *meta*-, or *para*-position were dissolved in 1 c.c. of ethanol and added to the jars containing *Elodea*. The final concentrations of the halogenated benzoic acids were 1×10^{-4}, 1×10^{-5}, and 1×10^{-6} M. One c.c. of ethanol was added to each control jar. All solutions were replaced every seven days. The experiment was conducted in a greenhouse and replicated three times over a four-month period. While the absolute responses to the acids varied from replication to replication, the relative responses to each acid were the same in each replication.

Data on total length and number of buds and roots were taken at weekly intervals for four weeks. Table 1 gives the total data for one replication. All shoots, regardless of treatment, had three or four buds. The chloro-substituted benzoic acids had little effect on number of roots. At the highest concentration iodo- and bromo-benzoic acids substituted in either the *ortho*- or *para*-positions inhibited the eruption of roots; at 1×10^{-5} M the same compounds had little effect on root number while at the lowest concentration they led to a greater number of roots. *m*-Iodobenzoic acid had little effect on the number of roots. The two highest concentrations of *m*-bromobenzoic acid had little effect on root number while the lowest concentration increased the number of roots.

The *m*-iodo- and *m*-bromo-substituted acids had little effect on shoot elongation. In general, increasing the concentrations of the *ortho*- and *para*-iodo- and bromo-benzoic acids and all chlorobenzoic acids led to inhibition of shoot elongation. There appeared to be little correlation between shoot elongation and root emergence. A compound, that is, *p*-chlorobenzoic acid, could affect elongation and not affect root emergence, or conversely, a compound, that is, *m*-bromobenzoic acid, could affect root emergence but have little effect on elongation. Where a compound did affect both root emergence and stem elongation, that is, *p*-bromobenzoic acid, the magnitude of the effects were quite different.

It would appear that halogenated benzoic acids can affect both stem elongation and differentiation in *E. densa*. Microscopic examination of sections through the nodal regions of shoots similar to those used in this experiment showed complete absence of bud and root primordia. It would seem, therefore, that in *Elodea* halogenated benzoic acids have no effect on initiation of bud primordia, enhance the differentiation of root primordia and in addition stimulate elongation of the stem. The effects of the acids on root primordia initiation and stem elongation appeared to be separate and not a result of an interaction. That is, the acids do not appear to affect elongation first and then elongation results in root differentiation and eruption. If shoots 10 or 15 cm long were treated with the acids, the results so far as elongation was concerned were identical to that of the 25 cm shoots. None of the two shorter shoot-lengths showed either buds or roots at the end of four weeks. Once again it would appear that the benzoic acids were affecting elongation without affecting primordia differentiation.

Table 1. EFFECT OF VARIOUS HALOGENATED BENZOIC ACIDS ON STEM ELONGATION AND NUMBER OF ROOTS IN *Elodea densa* AFTER FOUR WEEKS OF TREATMENT. PRIOR TO TREATMENT THERE WERE NO ROOTS AND STEM LENGTH WAS 25 CM

Controls	6, 6, 7	28, 29, 29

Van Overbeek[2] found 50γ equivalents of indolyl-3-acetic acid (IAA) per kilogram fresh weight of *Elodea*. This is a relatively high concentration. Niedergang-Kamien and Skoog[3] have reported that 2,3,5-tri-iodobenzoic acid interfered with the polar movement of IAA. It is possible, therefore, that the benzoic acids here were interfering with the IAA metabolism. It is interesting that the benzoic acids had no effect on the formation of bud primordia but had definite effects on the formation of root primordia and on stem elongation. In all three processes, IAA has been reported to play an important part. Since both treated and control shoots formed roots the benzoic acids did not initiate a new process but enhanced an already occurring process.

The *ortho*- and *para*-substituted halogenated benzoic acids show more reactivity in terrestrial plants than the *meta*-substituted compounds, which show little activity. The same position effects were seen in *Elodea*. The low activity of the chloro-substituted compounds on *Elodea* is at variance with the high activity of these compounds on terrestrial plants.

Branched Lint Hairs in Cotton, *Gossypium hirsutum*

DURING investigations into the development of lint hairs in Upland cotton (*Gossypium hirsutum* L.) branched hairs were frequently observed in slides examined microscopically. Up to 9 per cent of the hairs on a slide were found to be branched and occasionally two or more branches were observed on a single hair. Branched hairs were found to occur in a wide range of cotton types within the species. The branches were blunt, tubular structures with a large

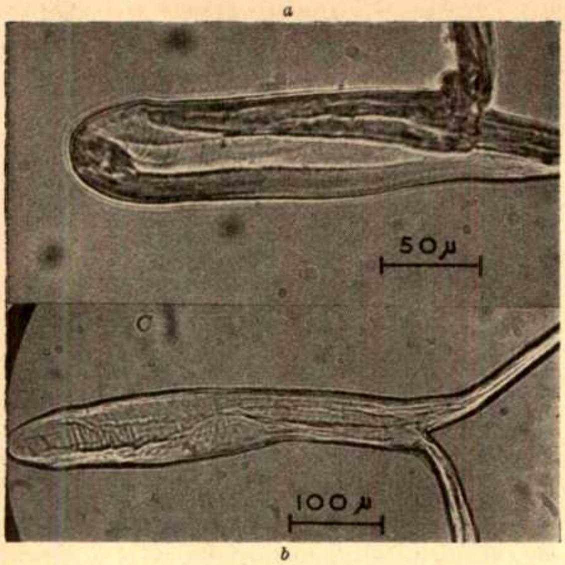

Fig. 1. Photomicrographs of lint hair branches in *Gossypium hirsutum*. The large central lumen is visible in *a*; in *b* the fibrillar nature of the cellulose thickening can be distinguished near the distal end of the branch

central lumen continuous with the lumen of the remainder of the hair cell (Fig. 1*a*). They varied in length from 50µ to more than 1,200µ and were approximately 50µ in diameter.

It is suggested that the branches are formed following the occurrence of folds in the lint hairs during an early stage in their development and before secondary cellulose deposition is initiated. The walls on the inside of the fold fuse, and a large proportion of the fused wall material is resorbed by the cytoplasm of the cell to leave a single, central lumen in the folded region of the hair. Secondary thickening later takes place throughout the walls of the hair including those of the branch.

A number of observed facts support this explanation: a branch is usually twice as wide as the remainder of the hair cell; the unbranched parts of the hair cell always meet at an acute angle at the base of the branch; it is possible to distinguish a definite fibrillar structure extending across the whole wall of the branch, indicating that it has been thickened as a single unit (Fig. 1*b*). The lint hairs are always folded to some extent in the developing boll and the complete doubling necessary for the formation of a branch in the way suggested could easily occur.

The walls of growing plant cells are extremely labile and can be digested by the cell in certain circumstances[1]. In the Cladophoraceae, for example, the walls of all but the basal cells may be pierced by holes which are digested shortly before the liberation of swarmers[2]. There is no reason to suppose that the septum formed by the fusion of the inside walls of the fold in the lint hairs of cotton could not be digested and resorbed in a similar way.

I thank Prof. R. D. Preston for comments on the above explanation of the development of branched lint hairs; and Dr. D. A. Perry, who took the photomicrographs.

MICROBIOLOGY

Mutants of *Salmonella* with Unusually Low Toxicity for Mice

IT has been previously reported from our laboratory[1-3] that galactose-sensitive mutants of *Salmonella enteritidis* and *Salmonella typhimurium*, which are defective in uridine diphospho-galactose-4-epimerase (epimerase), contain only glucose in their cell wall, entirely lacking galactose, rhamnose, mannose and tyvelose (or abequose), which are regarded as the usual constituents of the cell wall sugars of wild-type cells. These cell wall polysaccharides are known to constitute a part of the endotoxins of bacteria[4,5], and it seemed of interest to examine what effect the alteration in the composition of polysaccharides might have on toxicity of bacteria.

The properties of the strains used in the investigation reported here are summarized in Table 1, together with the principal results. As seen in Table 1, while the cell wall of the wild-type strains contained glucose, galactose, mannose, rhamnose and tyvelose (or abequose), a rough mutant ($11Rx$) of *S. enteritidis* had only glucose and galactose in its cell wall, which confirmed the observation of Westphal's group[6]. It was also found that the cell wall of epimerase-less mutants contained only glucose.

In the first series of the experiments, the toxicity of heat-killed cells was examined in regard to their lethal effects on mice. Heat-killed cells were prepared by heating saline suspension of an 18-h agar culture of each strain at 58° C for 60 min. *dd* strain mice weighing about 16 g were injected intraperitoneally with 0·3 ml. of various dilutions of the heat-killed cell suspension, and deaths in each group of five mice were recorded during a period of 72 h. As shown in Table 1, mutant $11Rx$ was somewhat less toxic than its wild-type. Furthermore, the heat-killed cells of epimerase-less mutants of both *S. enteritidis* and *S. typhimurium* were found to have extremely low toxicity; the LD_{50} appeared to be much larger than 16 mg. The strains of *Salmonella* having such low toxicity have never been experienced before in our laboratory.

It is generally believed that most, if not all, of the toxicity of heat-killed bacteria is due to the lipopolysaccharide (endotoxin) they contain. Therefore, it seemed of interest to compare the amount of endotoxin extractable from the cell, and also to compare the toxicity of extracted endotoxin from the various strains mentioned here. Lipopolysaccharide was obtained from each strain by the phenol–water procedure[7], which is believed to give nearly quantitative yields of the material and then purified by ultracentrifugation. As shown in Table 1, the yield of lipopolysaccharide was poor in the strain of low toxicity. At least in the case of $11\text{–}1\text{–}M$, there is evidence that the low yield is not due to the difficulty of extraction[8]. When the lethal toxicity for mice of lipopolysaccharide was determined in the same way as for heat-killed cells, no remarkable difference in the toxicity was found among the lipopolysaccharides from various strains. Consequently, at least in the case of mutant $11Rx$, the low toxicity of heat-killed cells may be explained by the low content of endotoxin, but the toxicity of heat-killed cells of epimeraseless mutants is too low to be explained by the content of lipopolysaccharide alone. It appears that the mode of existence of lipopolysaccharide, especially its association with the other constituents of the cell

* These analyses were carried out as previously described (ref, 2).

Hexosamines and heptoses (probably occurring in phosphorylated form) were removed during the deionization procedure, and thus were not demonstrated.

† Fractions = $\frac{\text{total number of dead mice}}{\text{total number of mice tested}}$ (by administration of 16 mg of heat-killed cells).

Abbreviations: Glu., glucose; Gal., galactose; Man., mannose; Rha., rhamnose; Tyv., tyvelose; Abe., abequose.

wall, may play an important part in the manifestation of the toxicity of heat-killed cells. It has been shown that the live cells of epimerase-less mutants are markedly less virulent for mice than those of wild-type[9], and this fact might also be related to the results obtained in this investigation.

The finding that lipopolysaccharide from epimerase-less mutants, in spite of the absence of various sugars other than glucose, showed the same degree of toxicity as that of the wild-type, confirmed the conclusion of Westphal and Lüderitz[5] that the polysaccharide part of endotoxin was not directly related to the toxicity.

I thank Prof. O. Westphal, Prof. D. Ushiba, and Dr. K. Saito for suggestions and discussions, and also to Drs. T. Fukasawa and H. Nikaido for advice and for carrying out the analysis of cell wall and purification of the lipopolysaccharides.

Plant Protein Agar, a Medium for the Isolation and Estimation of Proteolytic Organisms in Grassland Soils

GELATIN, casein and occasionally albumen are used for isolation and counting of proteolytic soil organisms. Among the principal substrates for such organisms in grassland soils will be the dead tillers, the sloughed off roots and, after ploughing, the stubble and root mat of the sward. Since plant protein will be present in plant residues, its choice as a medium for proteolytic soil organisms seems in this case more logical than that of either gelatin, casein or albumen, proteins of animal origin. Waksman and Starkey[1] have examined the decomposition of vegetable proteins by some soil organisms.

The plant protein used in these experiments was prepared by a method of Tilley and Wilson (personal communication). Juice expressed from fresh minced lucerne was heated to 55° C and centrifuged to remove chloroplastic material. Sulphuric acid (2 N) was added to precipitate the cytoplasmic protein, which was washed with hot water, alcohol and acetone. It was allowed to dry in air to yield a white powder of about 14 per cent nitrogen content. The dried powder was ground in demineralized water (25 g/500 ml.) in a ball mill for 5 h to give a uniform suspension. This was sterilized by steaming on three consecutive days. Since the suspension coagulates on heating, shaking at intervals during sterilization, especially on the first day, is essential.

The protein–agar medium was prepared by adding plant protein suspension to mineral salts agar containing 0·01 per cent Oxoid yeast extract, to give a final concentration of 8 per cent protein suspension. The *p*H was adjusted to 7 by the addition of sodium carbonate solution before the addition of the protein suspension.

This medium has been used by Grossbard and Hall[2,3] primarily for counting proteolytic bacteria, fungi and Streptomycetaceae in soils of various plots forming part of an experiment on the effects of leys on

I.105	85·1	6	23 2	4

Activity index scale based on $\log_2$ (area of lysis in mm²) soil fertility. The plate dilution method was used. Organisms were rated as proteolytic when, after 6 days of incubation at 25° C, the plates showed clear (sometimes transparent) zones around or underneath the microbial colony. The Streptomycetaceae gave well-defined areas of lysis the diameter of which was usually greater than that of the colony. The Streptomycetaceae were counted as a representative family of the Actinomycetales because of the ease of identification by their aerial mycelium under the low-power microscope.

The relative proteolytic activities of various organisms were expressed in terms of the area of lysis in mm^2. On this an activity index was based[4]. A similar index was obtained for cellulolytic organisms cultured on mineral agar with cotton cellulose as the sole source of carbon[5]. These indices were used for a broad comparison of the proteolytic and cellulolytic activities of specific soil organisms. They serve as a criterion of the ability of these organisms to decompose plant residues (Table 1).

Plant protein agar has the advantage over gelatin agar in deriving from important forms of protein found in plant residues. Moreover, the zones of lysis can be read off directly from an untreated isolation plate. If gelatin agar is used the plates must first be flooded with $HgCl_2$ and HCl for the zones of lysis to become apparent. Consequently the organisms are killed and cannot later be isolated.

We thank Dr. William Davies for his help and Dr. J. M. A. Tilley and Mr. R. F. Wilson for preparation of plant protein.

Detection of Marine Alginolytic Bacteria

IN the examination of the hydrolases of algal polysaccharides in marine bacteria, a simple method to detect alginase is desirable[1]. A difficulty arises in the preparation of media because of the precipitation of alginate by the divalent ions in sea-water. The methods previously described were reviewed by Thjøtta and Kåss[2]. The disadvantages of these methods are that the measurement of decrease in viscosity of an alginate broth requires a special apparatus[2], and the alginate agar medium of Waksman *et al.*[3] cannot be used for marine strains which liquefy agar. The preferred method is one based on the liquefaction of an alginate gel. A simple method for the formation of this gel in a sea-water medium is described here. The alginate gel is formed by the slow diffusion of divalent ions from a sea-water agar medium into a solution of sodium alginate. This method is similar to the double-layer technique for the preparation of a pectate gel[4].

A modified Hugh and Leifson medium[5] was chosen as the base medium and consisted of sea-water, 100 ml.; dipotassium hydrogen phosphate, 0·03 g; trypticase (Baltimore Biological Lab.), 0·25 g; and agar (Difco, 'Bacto-agar'), 1·5 g, but any sea-water agar medium may be used.

Table 1. HYDROLYSIS OF ALGINATE AND AGAR

	Alginate	Agar*	Alginate/agar†
Ps. carrageenovora	Liquefied	−	−
Ps. atlantica	Pit	+	+
Strain 7	−	+	

+ Clear area around colony.
* Gram's iodine.
† Clear area around colony indicates use of alginate in alginate/agar medium of Waksman *et al.* (ref. 3).

The upper layer contained sodium alginate (Hallmark, 'Manucol *SS/LM*, (η)' 11·6)[6] 2·5 g; sodium chloride 3·0 g; dipotassium hydrogen phosphate 0·03 g; and distilled water 100 ml. A mixture of the dry sodium chloride and alginate was added slowly to a solution of the dipotassium hydrogen phosphate while stirring vigorously. This medium had a pH of 7·0 after autoclaving for 15 min at 121° C. A layer (0·5 cm deep) of the sterile solution of sodium alginate was poured over 15–20 ml. of the agar base in a Petri dish.

The strength of the alginate gel depends on the molecular weight and concentration of the sodium alginate, the concentration of divalent ions in the sea-water, and the rate of ion exchange which leads to the formation of the alginate gel. For the purposes of this test a gel equivalent to that obtained with 1 per cent agar (Difco 'Bacto-agar') was desired. Under the conditions described here, a suitable gel was obtained 1 h after the alginate was poured over the agar base layer.

Precautions were taken to remove the moisture which was produced by the syneresis of the alginate gel. The agar base was dried initially for 24–48 h at 37° C and an absorbent disk was placed in the glass Petri plate cover. If necessary the alginate surface was dried with the aid of a bunsen flame.

Hydrolysis of the alginate was indicated by complete liquefaction of the gel or the formation of a depression around the colony. This pit was easily demonstrated if the alginate layer was floated off the surface of the agar base layer, with a 5 per cent solution of calcium chloride. After the alginate layer had been removed, the agar was flooded with a solution of iodine prepared according to Gram, to determine whether it had been hydrolysed by the bacteria.

A loopful from a 24 h culture of *Pseudomonas atlantica*, *Ps. carrageenovora* and a number of unidentified marine bacteria was placed on the surface of the dry alginate gel. The plates were incubated at 25° C. The results in Table 1 show that the alginate was liquefied by *Ps. carrageenovora*. This strain hydrolysed κ-carrageenin but not agarose[7]. A pit was formed in the alginate gel with *Ps. atlantica*.

In the double layer medium a depression was observed in the alginate around the colony of strain 7. However, when the alginate layer was floated off the agar base layer, it was seen that the alginate was not hydrolysed. This pit was due to the sinking of the intact alginate gel into a deep hole produced in the agar by an agarase. Strain 7 was an unidentified marine bacterium which liquefied agar.

The double-layer method was compared with Waksman's alginate agar medium[3] prepared according to Skerman[8]. A clear area around the colony was obtained with *Ps. atlantica* but not with *Ps. carrageenovora*, the strain which actively liquefied the alginate gel (Table 1).

High concentrations of calcium ions in the base layer increased the strength of the alginate gel, caused excessive syneresis, and inhibited the alginase of *Ps. carrageenovora* (Table 2).

This method can also be used for detecting the hydrolysis of alginate by soil bacteria. For this

Table 2. EFFECT OF CALCIUM ON ALGINATE GEL

Calcium chloride in sea-water agar base (%)	Syneresis	Gel strength	Activity of alginase *Ps. carrageenovora*
0	–	–+	Liquefaction
0·1	–	+	Liquefaction
0·25	–+	+	Pit 25 mm
0·5	+	++	Pit 25 mm
1·0	++	+++	Pit 10 mm

purpose calcium is added to a soil extract agar medium and the sodium alginate is dissolved in an aqueous solution of dipotassium hydrogen phosphate.

Aminopterin as an Inducing Agent in Bacteriocinogenic Bacteria

INDUCTION of lysogenic bacteria was first produced by the use of ultra-violet light[1]. It was shown later that other radiations[2], nitrogen mustard, ethylene-imines, epoxides and organic peroxides[3] can also induce lysogenic bacteria to produce phage. The process of induction is not yet clear. Several lines of evidence indicate that the primary lesion initiated by inducing agents could be an alteration in the nucleic acid economy of the host, an effect of unbalanced growth[4].

In 1952[5] it was demonstrated that exposure of bacteriocinogenic bacteria to ultra-violet light induces the production of bacteriocin. The fact that phage production and bacteriocin formation are induced by the same agents, and many other similarities[6] suggest that the mechanism of induction might be analogous in both systems. Since bacteriophage production appears to be the more complex of the two systems, it may be easier to study the triggering effect of induction in the case of bacteriocins.

The experiments described here were performed using strain *P* of *Pasteurella pestis*, which produces bacteriocin, when irradiated with ultra-violet light[7,8] or when treated with mytomycin *C*[9]. Cultures of exponentially grown cells start to produce bacteriocin almost immediately after irradiation[7], that is, too early for the resumption of DNA synthesis to occur. If DNA synthesis is, indeed, not needed for bacteriocin production (in contrast to phage production), the system will permit the demonstration of triggering the induction even by a substance which will stop synthesis of DNA completely.

Aminopterin (California Corporation for Biochemical Research), when given in a dose of 200 γ/ml., induces the *P* strain of *P. pestis* to produce bacteriocin. In a typical experiment, 200 γ/ml. of aminopterin was added to a sample of an exponentially grown culture of *Pasteurella pestis* in synthetic medium[10]. Another sample was irradiated with ultra-violet light. The tubes containing these samples and the control were immersed in a water bath at 37° C, for 3 h. Chloroform was then added to each culture, to kill the bacteria, and bacteriocin (pesticin) in the medium titrated after decantation, as described previously[7]. The titre of the control was less than 1×10^2 arbitrary units/ml., the titre of the irradiated culture 1×10^4 and that of the aminopterin-treated culture 5×10^3 arbitrary units/ml.

Attempts to reverse induction of aminopterin by thymine, thymidine, folic acid or folinic acid have failed so far, both when these metabolites were added to the bacteria 1 h before or immediately after induction.

GENETICS

Apparent Genetic Recombination in a Blue-Green Alga

THE blue-green algae (Myxophyceae) have generally been thought to be devoid of sexuality[1,2], although no genetical evidence for or against this supposition seems to have been reported so far. This communication describes experimental results obtained with a unicellular blue-green alga, generally known as *Anacystis nidulans* (Myers' strain), which seem to indicate the occurrence of sexual or parasexual phenomena in this organism.

From the wild-stock, strains of the alga which are, *inter alia*, about ten times as resistant to penicillin and streptomycin as the sensitive (parent) strain were derived by a few sub-cultures in basal medium (slightly modified Medium *C* of Kratz and Myers[3], diluted with equal parts of water) supplemented with gradually increasing concentrations of the respective antibiotic. These strains seem stable; a streptomycin-resistant strain has been passed through 40 sub-cultures in the absence of streptomycin without having lost its resistance.

Each of the resistant strains was tested for cross-resistance to the other antibiotic and found not to be cross-resistant. They were also inoculated—separately and jointly—into media which contained both the antibiotics. No growth was found to have occurred in any case even after six weeks.

Inocula from streptomycin-resistant and penicillin-resistant strains were then transferred together into the basal medium containing no antibiotics. At various times, inocula were withdrawn from the mixture and transferred to culture flasks containing both the antibiotics. Out of a total of 36 such flasks (in different experiments) growth occurred in 10. Two typical growth-curves are shown in Fig. 1. The duration of the lag-phase was found to vary from 8–13 days. Since neither of the strains can by itself grow in flasks containing both streptomycin and penicillin, in contrast to inocula from the basal mix of the two strains which can, it is highly probable that growth in the latter case is due to the appearance of

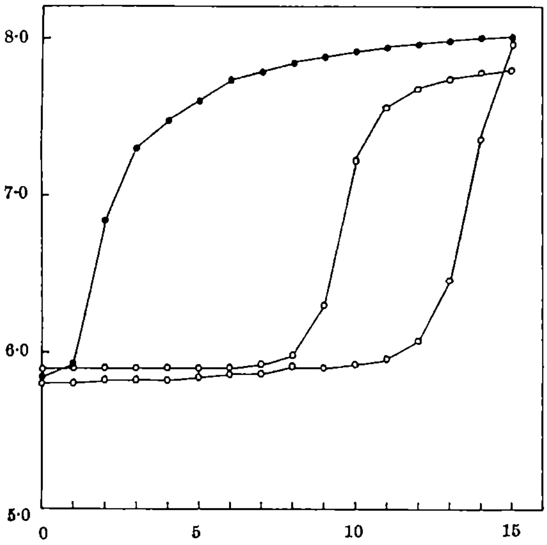

Fig. 1. ○, Growth curves (in $\log_{10}$ units) of 2-week-old inoculum from basal mix of penicillin- and streptomycin-resistant strains in medium containing both antibiotics; ●, growth curve of a double-resistant strain (resistant to penicillin and streptomycin) in medium containing chloramphenicol only

recombinant cells that are resistant to both the antibiotics. The other possible class of recombinant, namely, the double-sensitive, obviously could not be detected because of its inability to grow in the selective medium. It has so far proved impossible to grow clones from single cells of *Anacystis* on solid media so that it cannot yet be asserted that recombination has occurred within individual cells. However, the fact that no growth occurs when inocula of two resistant strains that have not previously grown together are introduced into an antibiotic mixture appears to rule out the possibility that some other mechanism is concerned. This conclusion is further supported by the fact that growth of inocula from the basal mix in medium containing both antibiotics occurred in only some, not all, flasks—an observation that is entirely in keeping with expectation if we attribute growth in these flasks to have been due to the chance inclusion and random distribution of rare recombinant cells among some of the otherwise identical inocula. On the other hand, if some enzymatic or 'antibioticase' mechanisms were concerned, uniform growth would be expected in all flasks.

Tentative estimates indicate that the double-resistant recombinants appear at a frequency of 1 in about 10^8 cells of the parental population—a figure which agrees closely with that reported originally by Lederberg and Tatum[4] (namely, 1 in about 10^6–10^7) for *Escherichia coli K*–12, although mutant donor strains of this bacterium showing a much higher degree of fertility have since been isolated[5,6].

Single-step attempts to isolate a triple-resistant strain of *Anacystis nidulans* by inoculating from basal mix of three strains resistant respectively to streptomycin, penicillin and chloramphenicol into medium supplemented with the three antibiotics were unsuccessful. However, the double-resistant strain, isolated as a product of the cross between streptomycin- and penicillin-resistant strains (both of which are sensitive to chloramphenicol), was found to be able to grow in chloramphenicol medium (Fig. 1). Further work on these and other strains of the alga and also genetic transformation studies are in progress and will be published elsewhere.

I thank Prof. G. E. Fogg for his kind help and encouragement. I also thank Dr. D. Wilkie for valuable suggestions, and the Commonwealth Scholarship Commission in the United Kingdom for the award of a scholarship during the tenure of which this work is being carried out.

CYTOLOGY

Chromosome Breakage in *Vicia faba* by Monochloramine

THE investigations reported here were prompted by the finding that our distilled water was producing chromosome breakage when used for soaking *Vicia faba* seeds. Monochloramine is used in the disinfection of the Atlanta, Georgia, water system and distils over quite readily. The activity of monochloramine as a bactericidal and virucidal agent has been examined by others[1], but the specific cytological effects apparently have not, and it is not included in lists of the chloramines[2] which have been tested by various screening agencies. Organic chloramines, which include the nitrogen mustard group, have found extensive application where the use of cytotoxic agents are required.

In these investigations a comparison was made between hypochlorous acid, monochloramine (NH_2Cl) and a nitrogen mustard as concerns their capacity for inducing chromosome breakage in the root meristems of *Vicia faba*. The hypochlorous acid was obtained through the addition of a commercial preparation ('Clorox') and the nitrogen mustard was commercially available mechlorethamine hydrochloride (Mustargen, Merck). Monochloramine was produced by steam distillation of ammonia hydroxide plus hypochlorous acid into an aqueous solution buffered at *p*H 9 with 10^{-2} molar sodium borate. A slight excess of hypochlorous acid was used to avoid the presence of excess ammonia in the distillate. The reaction proceeds as follows:

$$NH_3 + OCl^- \rightarrow NH_2Cl + OH^-$$

Monochloramine concentration was determined in the spectrophotometer, having a specific absorbance at 240 mμ[3]. A volumetric analysis (Palin method) was also used[4]. The concentration of hypochlorous acid was determined by the potassium iodide method[5]. Dosing concentrations were obtained by dilution; in the case of the monochloramine all solutions were 10^{-2} M sodium borate. Imbibed seeds of *Vicia faba* were soaked in the various solutions for a period of 60 min, washed in dilute sodium thiosulphate solution, and then allowed to germinate in the dark at 19° C until the radicals were about 2 cm long. At this time the first cell divisions occur and propionic-carmine stained preparations were made. Table 1 presents the results of these experiments. Those

Table 1

Treatment	Concentration (M)	No. of anaphases scored	No. abnormal	Abnormal (%)
OCl^-, 60 min	10^{-2}	518	27	5·2
NH_2Cl, 60 min	10^{-4}	582	139	24·0
Mechlorethamine HCl (Mustargen, Merck), 60 min	10^{-6}	631	183	29·0
Control 10^{-2} M $Na_2B_4O_7$	—	600	7	1·0

Table 2

Compound	Relative effectiveness
OCl^-	1
NH_2Cl	500
$CH_3N(CH_2CH_2Cl)_2 \cdot HCl$	60,000

anaphase figures which contained bridges and/or fragments were considered abnormal.

A 60-min exposure to 10^{-4} molar monochloramine produced 24 per cent abnormal anaphases while a 10^{-6} molar concentration of nitrogen mustard produced 29 per cent abnormal anaphases. A concentration of 10^{-2} molar hypochlorous acid was required to produce 5·2 per cent abnormal anaphases. The relative effectiveness of the three compounds in producing abnormal anaphases is presented in Table 2.

Nitrogen mustard and monochloramine at these concentrations did not produce visible external browning of the plant embryos, whereas the hypochlorous acid caused extensive surface effects. It would appear that monochloramine resembles the organic chloramines (nitrogen mustards) in its capacity to produce chromosome breakage at concentrations which apparently produce little evidence of tissue damage.

SOIL SCIENCE

Formation of Gibbsite as a Primary Weathering Product of Acid Igneous Rocks

ONLY detailed sampling of early weathering stages combined with suitable analytical techniques can reveal the presence of gibbsite as a primary weathering product in certain weathering crusts of acid igneous rocks. It is therefore instructive to examine the findings of some previous workers in relation to the methods they used.

Harrison[1] found that acid igneous rocks give rise directly to kaolinitic earth without the intermediate formation of gibbsite, and Humbert[2] found no evidence to support the presence of gibbsite in weathered granitic material. Harrison sampled the weathering stages in detail but in examining thin sections under the microscope small amounts of gibbsite might have escaped detection. Humbert analysed a late weathering stage and may therefore have missed gibbsite present only at an earlier stage. Leneuf[3] sampled weathering stages of acid igneous rocks in detail and subjected samples of silt and clay to X-ray and differential thermal analysis. He concluded that the occurrence of gibbsite in the early stages of weathering of granite is well defined but only transitory. This conclusion is supported by the study of a weathered granite in Southern Rhodesia.

Table 1. SEMI-QUANTITATIVE ESTIMATES OF GIBBSITE AND KAOLINITE IN CLAY EXTRACTED FROM A GRANITIC WEATHERING CRUST NEAR SALISBURY, SOUTHERN RHODESIA

Sample No.	Gibbsite (%)	Kaolinite (%)
A	< 5	100
B	35	65
C	25	5
D	10	< 5

The site examined is a broadly curved hill-top near Salisbury at an elevation of about 5,140 ft. on the Gondwanaland surface. The climate is sub-tropical and divides naturally into a wet season and a dry season. A mean annual rainfall of 33 in. and a mean annual temperature of 19° C have been recorded at the Salisbury Observatory. A leached, pallid soil 18 in. deep is underlain by an argillaceous weathered crust 12 ft. thick, over a 3 in. layer of red arenaceous material, over grey, weathered granite of undetermined thickness. A description of samples of the weathered granite is given in Fig. 1 together with the differential thermal curves. The temperature recorded is that of the inert material. The endothermic peak of gibbsite occurs around 350° C and the kaolinite peak at about 600° C. The endothermic

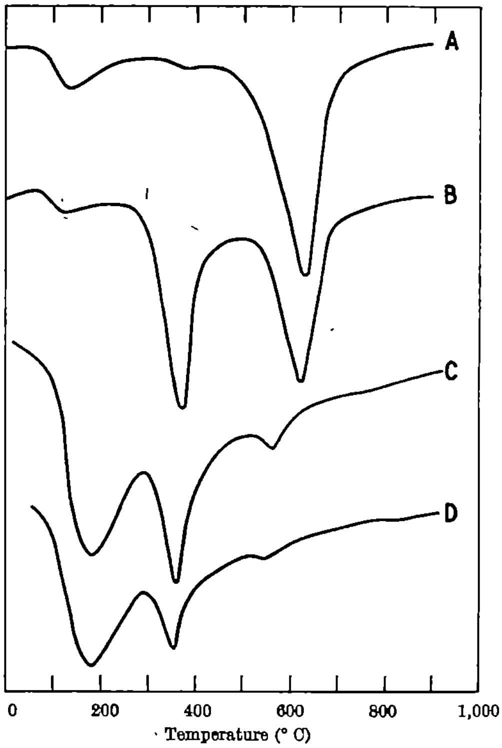

Fig. 1. Differential thermal curves for clay from a granitic weathering crust near Salisbury, Southern Rhodesia. *A*, 12 ft. 10 in. depth, red argillaceous material with abundant weathered minerals and clayskins (19 per cent clay); *B*, 13 ft. 6 in. depth, red arenaceous material, consisting largely of weatherable minerals (7 per cent clay); *C*, 13 ft. 9 in. depth, grey weathered granite that can easily be broken in the hand (0 3 per cent clay); *D*, 14 ft. 11 in. depth, grey weathered granite that can be broken with difficulty or not at all in the hand (0 3 per cent clay)

peak in the region of 180° C is probably due to amorphous material such as alumina gels, but allophane may also be present. The presence of gibbsite in samples *B*, *C* and *D* and kaolinite in all samples was confirmed by X-ray analysis. Semi-quantitative estimates of gibbsite and kaolinite (Table 1) were obtained from Fig. 1 by reference to a differential thermal trace made by standard kaolinite after allowing for the amount of water lost on heating gibbsite relative to that lost on heating kaolinite.

I thank Mr. G. Brown, Dr. R. Greene-Kelly and the late Dr. A. Muir for allowing me to use X-ray and differential thermal equipment at Rothamsted Experimental Station.

Density of Clay-Water Systems

A RECENT paper by Deeds and Van Olphen[1] gives density data for the bentonite–water system which is not in agreement with the results of Anderson and Low[2]. Since the pressure chamber method designed by the latter authors gave promise of being extremely accurate, it seems necessary to re-examine their results.

Anderson's method makes use of the slope of the curve of water content versus volume of the clay–water system. This gives directly the partial specific volume of the water phase, so that changes of slope are interpreted as changes of specific volume. If we plot the deviations of Anderson's points[3] from a straight line, changes of slope can be magnified 100 or more times, allowing a visual estimation of their significance and reliability. When this is done, it is observed that each curve can be considered as a small number of straight line segments, with discontinuities of slope and water content occurring near some of the points at which the mercury capillary was refilled. A sample curve is shown in Fig. 1, and curves of partial density obtained in this way averaged over duplicate sets of results are shown in Fig. 2. (I can supply lists of deviations from straight lines of slope 0·990 for the eight tables of Anderson's thesis. These lists omit the 7 per cent of points containing major misprints. The lines were fitted at water contents between 3·5 and 4·5 gm/gm.)

A general decrease in density is indicated with decreasing water content, but the reliability of the results is obviously low, and detailed comparisons of the four curves are valueless. In addition, the density at high water contents does not agree well with the known density of water, suggesting that the calibration of the capillary or microburette may have been slightly in error.

It is difficult to suggest any sources of inaccuracy in the pressure chamber method which were not carefully investigated by Anderson and Low, and it is especially difficult to understand why refilling the mercury capillary should cause discontinuity of slope as it apparently does.

However, further evidence of inconsistency is obtained if we apply the equation $V = w\bar{v}_w + m\bar{v}_m$[3] to the results. We may use this equation in the form

$$V + \delta = w\bar{v}_w + mv_m + m\left(\frac{\partial V_w}{\partial m}\right)_w$$

where V is the experimentally measured total volume; δ a volume correction constant for each run; w and m are the weights of water and clay respectively in the sample; $\bar{v}_w$ is the partial specific volume of water; v_m the (constant) specific volume of the clay; V_w is the volume of water in the sample.

If the density of the water decreases near the clay surface in the manner of Anderson and Low, the final term must be a small positive quantity which increases with decreasing water content. δ can be evaluated at high water contents, and the other quantities are known. (If the water density is still varying at the highest water contents available, δ will include a small term due to the derivative $\left(\frac{\partial V_w}{\partial m}\right)_w$. This does not affect the argument.)

For every set of experimental results the last term in the equation is negative, and it usually becomes more negative with decreasing water content. Both these results are contrary to expectation; they are not significantly affected by assuming different values of clay or water density within wide limits.

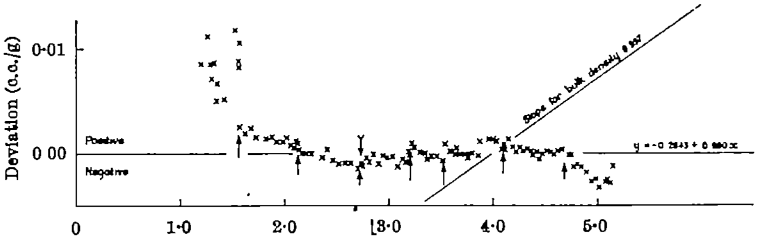

Fig. 1. Deviations of Anderson's Table 9 from a straight line of slope 0·990. Arrows are refilling points. Lithium bentonite at 25° C.

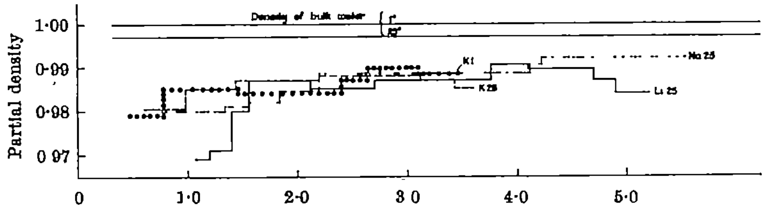

Fig. 2. Average density values from Anderson's data. Lithium, sodium and potassium bentonite at 25° C., potassium bentonite at 1° C.

Until such anomalies are cleared up it must be concluded that variation of the water density at distances greater than a few molecular layers from the clay surface has not yet been demonstrated.

FORTHCOMING EVENTS

Monday, December 17

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5 p m.—Mr. R. H. Hughes: "Hong Kong—Far Eastern Meeting Point".

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, W.C.2), at 5.30 p m —Prof. H. E. M. Barlow, F.R.S.: "A Proposed New Method of Measuring Microwave Power and Impedance using Hall Effect in a Semiconductor"; "High-Frequency Radiation Pressure and Hall Effect in Semiconductors"; "A Microwave Electrostatic Wattmeter".

Institute of Metal Finishing (at the Northampton College of Technology, St. John Street, London, E.C.1), at 6.15 p.m.—Mr. J. Carder: "Satin Nickel + Chromium Plating".

Monday, December 17—Tuesday, December 18

Association of Applied Biologists (in the Physics Department, Imperial College of Science and Technology, London, S.W.7), at 2.30 p.m. on Monday and 10.30 a.m. on Tuesday—General Meeting.

Tuesday, December 18

Institution of Electrical Engineers, Science and General Division P G.S.8 (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Television in the Service of Technical Education" opened by Mr. J. Scupham.

Institution of Mechanical Engineers, Internal Combustion Engines Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Are the Technical and Quality Standards in the Component Suppliers' Industry Good Enough ?".

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Dr. F. C. Harper. "Wear Testing of Flooring Materials".

Wednesday, December 19

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. R. H. Clarke: Pressure Oscillations and Fall-out Downdraughts"; Mr. J. S. Sawyer. "Gravity Waves in the Atmosphere as a Three-Dimensional Problem".

British Institution of Radio Engineers, Electro-Acoustics Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Symposium on "Vibration Testing".

Institution of Electrical Engineers, Power Division (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. D. A. Davis, Mr D. J. W. Richards and Mr. R. A. Scriven: "Investigation of Conductor Oscillation on the 275kV Crossing over the Rivers Severn and Wye".

Institution of Mechanical Engineers, Nuclear Energy Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m. —Discussion on "The Value of Theoretical Fault Condition Analysis".

Society for Analytical Chemistry, Microchemistry Group (at "The Feathers", Tudor Street, London, E.C.4), at 6.30 p.m.—Discussion Meeting.

Thursday, December 20

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m —Mr. D. J. Batzer. "Investigation Into Jig Performance"; Dr. R. L. Stanton: "Elemental Constitution of the Black Star Orebodies, Mount Isa, Queensland, and Its Interpretation".

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. A. L. S. Corner: "Topological Light on Abelian Groups".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned.

Lecturer or Assistant Lecturer in Mathematical Statistics—The Registrar, The University, Manchester 13 (December 29).

Lecturer in Zoology at Fourah Bay College (The University College of Sierra Leone)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 31).

Senior Lecturer and a Lecturer in Physiology at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 1).

Research Assistant (with an ordinary or honours degree in science, or an equivalent qualification, which must include chemistry or biochemistry, and preferably zoology at least to "A" level) in the Department of Veterinary Anatomy, for work on animal reproduction—The Registrar, The University, Liverpool 3, quoting Ref. No. CV/215/N (January 2).

Lecturers (2) (with a degree in biochemistry, organic chemistry, physiology or pharmacology) in Biochemistry—The Secretary and Registrar, The University, Southampton (January 7).

Chair of Physics at Queen Elizabeth College—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 10).

Reader in Botany at Queen Elizabeth College—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 10).

Chair of Medical Physics tenable at the Postgraduate Medical School of London—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 14).

Professor of Zoology and Entomology at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, January 15).

Senior Lecturer in Forensic Medicine; and a Senior Lecturer in Psychiatry at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (January 15).

Lecturers (2) in Chemistry at the University of Sydney, Australia —The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 18).

Senior Lecturer in Theoretical Physics; and a Senior Lecturer in Physics at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, January 18).

Lecturer in Histology and Embryology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 21).

Lecturer in Microbiology in the Department of Agriculture, University of Sydney—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 25).

Lecturer (with research experience in socio-economic geography, for preference in Asia or Melanesia, with special reference to the geography of subsistence economics) in Geography at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Australia, January 25).

Junior Lecturers (2) in Mathematics—The Secretary of the Mathematical Institute, The University, 10 Parks Road, Oxford (January 31).

Lecturer or Senior Lecturer in Inorganic Chemistry at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W.1 (Australia and London, January 31).

Lecturer (qualified in pure or applied mathematics) in Mathematics; an Assistant in Mathematics; and a Research Fellow in Mathematics—The Secretary of University Court, The University, Glasgow (January 31).

Lecturer in the Department of Theoretical Physics—The Registrar, The University, Liverpool, quoting Ref. No. CV/208/N (February 1).

Assistant Lecturers, Lecturers or Senior Lecturers in the School of Biological Studies—The Registrar, University of East Anglia, Earlham Hall, Norwich, NOR 05G (February 11).

Chair of Archæology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, February 15).

Imperial Chemical Industries Research Fellows in Biochemistry, Chemistry, Engineering, Pharmacology or Physics —The Secretary of University Court, The University, Glasgow (February 28).

Imperial Chemical Industries Research Fellow in one of the following subjects: Chemistry, Biochemistry, Physics, Engineering, Chemo-therapy and related subjects—The Secretary, Academic Council, Queen's University of Belfast, Northern Ireland (March 1).

Assistant Lecturer (Demonstrator) in Anatomy, to undertake teaching and research—The Secretary, University College, Gower Street, London, W.C.1.

Assistant Professor (with a Ph.D. degree, some teaching and research experience, and preferably a flowering plant taxonomist) of Botany—The Dean, Faculty of Arts and Science, University of Alberta, Calgary, Alberta, Canada.

Biochemist (under 45, with a degree in chemistry or biochemistry with postgraduate experience, preferably in the problems of animal nutrition and/or physiology in the tropics) in the East African Agricultural and Forestry Research Organization, for work on biochemical problems in the Animal Husbandry Division—The Director of Recruitment, Department of Technical Co-operation, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting NF/RC. 264/348/01.

Demonstrator in Physics—The Registrar, The University, Nottingham.

Lecturers or Assistant Lecturers (2) (with experience in at least one of the following fields: microbiology, plant physiology or genetics) in the Department of Biology—Dr. G. Power, Acting Chairman, Department of Biology, University of Waterloo, Waterloo, Ontario, Canada.

Master for Physics (able to take advanced and scholarship work, with some mathematics); and a Master to take Chemistry (some advanced work available for suitably qualified man)—The Rector, Edinburgh Academy, Edinburgh 3.

Mathematician (some sixth form work available)—The Headmaster, Leeds Grammar School, Leeds, 6.

Physicist—Head, Department of Physics, Victoria College, Victoria, B.C., Canada.

Professor of Statistics at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C.1

Research Assistant (organic chemist or biochemist) in the Department of Textile Industries, to undertake work on polysaccharides of intervertebral discs and connective tissues—The Secretary, The Royal Infirmary, Bradford 9, and The Registrar, Bradford Institute of Technology, Bradford 7.

RESEARCH ASSISTANTS (well qualified physicists, preferably with some research or industrial experience) IN THE DEPARTMENT OF PHYSICS, to join research groups working in the fields of X-ray crystallography, nuclear physics, magnetism, print recognition and ophthalmic optics—The Registrar (Dept. 61/J), Bradford Institute of Technology, Bradford 7.

SENIOR LECTURER or LECTURER (with a first- or second-class honours degree in chemistry or chemical technology or equivalent, and preferably with postgraduate research experience) IN CHEMISTRY, to lecture to university degree students and to specialized courses, and assist with laboratory classes—The Registrar, Royal Military College of Science, Shrivenham, Swindon, Wiltshire.

A NORTH ATLANTIC INSTITUTE OF SCIENCE AND TECHNOLOGY

As a result of discussions at meetings of the Science Committee of the North Atlantic Treaty Organization, a study group was appointed, with Mr. Louis Armand as chairman and including as members Sir John Cockcroft and Sir Solly Zuckerman, with the view of making an independent study of ways whereby science in the Western World could be strengthened. The study group first met in September 1959, and its report, *Increasing the Effectiveness of Western Science*, published in the autumn of 1960[*], recommended, *inter alia*, further study by an appropriately chosen group of the establishment of an international institute of science and technology. On November 2, 1960, the North Atlantic Council authorized the appointment of a small high-level working group to examine this question and to formulate recommendations on specific possibilities and their feasibility.

This working group was duly appointed, its membership including Sir John Cockcroft and Dr. J. R. Killian, jun., as chairman, and its report was presented to the Council of the North Atlantic Treaty Organization on October 13, 1961, but was only released for publication in May 1962[†]. It represents the outcome not only of the Committee's own intensive deliberations but also of numerous formal and informal discussions with many leaders in the scientific and educational community. The group was unanimous in concluding that it is both feasible and desirable to establish in Europe an international institute of science and technology devoted to graduate and postdoctoral studies and operating at the pinnacle of the university system. Furthermore, it felt that the benefits which such an institution could bring to science, engineering and education, and thus to the welfare and security of the Western countries, made its establishment urgent. The working group concluded that to-day the widely recognized advantages of international efforts in science, together with the growing facility and effectiveness with which Western countries undertake co-operative efforts, provide an unprecedentedly favourable climate for establishing such an institution. The increasing interdependence of nations and the importance to scientific progress of free and cultivated international exchange set the stage for new joint efforts. Only, in fact, by such united efforts can the European countries, in spite of their rich traditions of scientific achievement, hope to maintain their levels and enhance their traditions in face of the resources possessed by the United States and the U.S.S.R.

In presenting these conclusions, the working group stresses its conviction that such an international institute, operating at the highest international level, would supplement rather than duplicate the scientific and technological departments of existing universities and institutes, which, no matter what their strength, find it increasingly difficult to cope with the demands on teaching and research created by the growth of science and the rising numbers of students. To meet this need, Western nations must sustain and reinforce existing institutions, as well as increase their number. New academic institutions of the highest class must also be established, and the working group believes that all Western nations could gain an educational resource not otherwise achievable by jointly sponsoring one of these new institutions and giving it an international format. Such an international institution would be able to combine some of the advantages of North American, British and Continental universities, and the experiment might also assist existing universities in their efforts to modify their systems and traditions to accord with modern conditions. Through its freedom to innovate, to make a fresh start, unencumbered by traditional habits, and to exploit the opportunities unique to its international status, an international institute could be a fresh stimulus to all institutions and add to the scope and diversity of Western education at the highest academic level.

Sir John Cockcroft has already strongly urged that Britain should take the lead in establishing such an institute as a considered part of her programme for university expansion, and it is obvious that whatever contribution is made by the United Kingdom it should be considered as part of that expansion. Furthermore, the working group urges that to launch such an institution should strengthen Western morale and demonstrate the intellectual strength, vigour and unity with which Western nations can work together. Equally, it should demonstrate that only in the Free World can a truly international educational institution, attractive to first-rate scholars from all countries, be achieved.

The working group was influenced by three other broad considerations. Besides the acute need throughout the Western world for more scientists and engineers of exceptional ability, there is a growing need for leaders and scholars in these fields who combine professional excellence with that broad understanding of Western culture and languages which could be gained in an international community of scholars. This breadth of education, experience and outlook will be increasingly vital as the economic and political unity of the Western World grows.

Secondly, merely to keep peace, the Free World must double and redouble the scientific capabilities in the immediate future, and to preserve its cherished freedom, its art and the humanities will be the easier if the increasing numbers of scientists and engineers are better trained and equipped to nourish their art at the very frontiers of science. It is a matter of fulfilling the Western World's own ideals, of providing itself with a richer and better life, and of having the resources as well as the desires to behave with generosity to less-favoured nations.

---

[†] Proposal for an International Institute of Science and Technology: Report of the Working Group appointed by the Secretary General of the North Atlantic Treaty Organization. Pp. 57. (Paris: North Atlantic Treaty Organization, 1962.)

Thirdly, the establishment of the European Organization for Nuclear Research (CERN) and other internationally sponsored research institutions has already shown the feasibility of financing and operating such institutions, and their existence encourages the view that an international institute of science and technology is a practicable project, though the working group did not at the same time recommend the establishment of an international foundation for the development of science and technology. Such a project was regarded as outside the terms of reference of the working group, which nevertheless informally records its support for the proposal. The report, in fact, includes the outline of a scheme for organizing such a foundation and suggests that its establishment should be considered by a suitable international body.

The report sets forth in some detail the objectives and plan for the proposed institute, including its organization and academic programme, the admission of students, appointment of staff and finance. A staff of 398 is suggested, of whom 133 would be senior, with 1,055 clerical and technical assistants, and a student body of 1,025, of whom 340 would be postdoctoral. A capital investment of 55 million dollars is envisaged with recurrent annual expenditure of some 16 million dollars.

The institute is to be in the fullest sense an international institution, sponsored by a group of nations and bringing together students and staff from many countries, seeking through its organization, spirit and motivation to imbue its students with a wider understanding of science and technology, and indeed of all learning. It would recognize the growing interrelations between different fields of learning and research, stressing in its structure and all its programmes the unity of knowledge and seeking to achieve a flexibility which promotes easy interrelations among fields and to avoid rigidly organized departments. Pitching its programme at the pinnacle of university education, it would seek to build a research programme of such quality and comprehensiveness as to provide the richest possible environment for nurturing scientists and engineers of exceptional creative ability—recognizing always that research and education are inseparable and being alert to identify important new fields of research and to educate scientists in these fields.

The institute would seek a closer association between pure and applied science, and besides fostering the closer association of the education of scientists and engineers, would seek to achieve a productive relation between science and technology. It would endeavour to respond to the need for greater stress on graduate education in engineering as well as in science, and for more versatile and adaptable engineers. Through the establishment of close relations with industry it would endeavour to facilitate the rapid application of new ideas arising from basic research. It would naturally become an international centre for scientific conferences and the exchange of ideas, and formal provision of a centre for advanced study should make it a mecca for outstanding scholars. An ultimate objective would be to include a strong programme devoted to the relation between science and society and the cultivation of the humanities and social sciences as partners of science and engineering.

Generally, the institute would provide freedom of scholarly opportunity at all levels, thus encouraging individual development and initiative and achieving an environment superlatively attractive to scholars for their work and professional growth. It is in accordance with this that only exceptionally talented students would be enrolled. The academic senate would recognize successful course work and independent research of high calibre by the award of a doctor's degree, and it is hoped that formal recognition of this degree in all member countries would contribute to the reduction of existing degree barriers among various countries.

These are large objectives, many of which already shape the programmes of leading universities and institutes in the Western World, and while the proposed plan offers no particular novel methods of pursuing them, other than the international character of the institute, the working group believes that the special combination of these objectives and their pursuit in an institute sponsored internationally could provide a new pattern representing an important new resource to the West. The nature of that contribution becomes a little clearer from the outlines of the proposed plan. The institute would be a graduate institution with no undergraduate students, and all students would engage in research and some in teaching. Besides emphasizing the intimate interrelation of research and teaching, in both aspects an interdisciplinary approach is desiderated.

To this end, besides the centre for advanced study already noted, the institute would establish a small number of research centres in specified areas requiring integration of diverse disciplines. In the first instance, these are suggested for applied mathematics and theoretical physics, technological processes and systems, materials research, earth sciences, and life sciences. Stress is laid on the importance of flexible organization and procedure, and the working group hopes that the institute will have the courage to discontinue centres and programmes that lose importance if more important programmes emerge that could replace them.

It should be clear from this brief summary of the proposals that while the participation of the United Kingdom in the scheme would represent an effort of which due account must be taken in the expansion of university and technological education in Britain, the effect on undergraduate education in the first instance will be only indirect. The contribution to postgraduate education could, however, be significant, even if Britain could scarcely expect to provide even 200 of the 1,000 student places. Apart, however, from the possibilities in regard to research, particularly in interdisciplinary fields, the institute might make a valuable contribution to the provision of the teaching staff, which promises to be the real bottleneck in university expansion. Further, it is possible that, if the flexibility which the working group desiderates so firmly can be achieved in practice, a lead might well be given to the solution of the problems which arise when research teams established around some distinguished scientist in a research institute or to share some highly expensive equipment lose their leader or find the field diminishes in importance. Viewed purely from this point of view of experiment in dealing with the major problems of research to-day, the proposal deserves serious consideration and if the other members of the North Atlantic Treaty Organization are prepared to join in establishing such an institute, there should be no hesitation on the part of the British Government in making its proportionate contribution to the capital and recurrent expenditure involved.

A NEW OXFORD DICTIONARY

Oxford Illustrated Dictionary

Text edited by J. Coulson, Prof. C. T. Carr, Lucy Hutchinson and Dorothy Eagle. Pp. xvi + 974. (Oxford : Clarendon Press, 1962.) 50*s*.

THE latest dictionary from the Clarendon Press is a break with tradition; however, as the preface points out, this is a well-planned break and as such represents the culmination of more than twenty years work. The *Oxford Illustrated Dictionary* extends to nearly 1,000 pages and contains more than 30,000 separate entries with more than 600 supporting drawings. Although it is the first of the Oxford English Dictionaries to make use of illustrations, it is not this that has revolutionized the Oxford Dictionary system, for from its own definitions this latest publication cannot truly be classified as either a dictionary or an encyclopædia. On one hand, it goes much farther than the traditional idea of a dictionary, and on the other it is not sufficiently extensive in its definitions to be used just as an encyclopædia. All in all, it represents an intermediate stage between the two.

The fact that a printing house steeped in tradition, as is the Clarendon Press so far as its dictionaries are concerned, should feel that there is a need for such a work is a consequence of the ever-increasing strides of science and technology. No longer is it sufficient to have a lexicon that deals solely with words, their use, spelling, significance, etc.; instead such a work must be supplemented by definitions of 'things'. The preface states that "the vocabulary has been chosen with an eye to the needs of one who may require either type of information. Information about words, however, is more often sought by the average user of a reference book than information about things and the vocabulary has therefore been based on that of the *Concise Oxford Dictionary* . . . ".

Special consideration has indeed been given to many terms in everyday use which would normally be excluded from an ordinary dictionary because of their technical and scientific character. For example, the entry for 'bacterium' carefully defines the organism, outlines the occurrence and activities of this kind of organism and, by illustration, indicates the differences between the coccus and the bacillus forms, giving as examples *Staphylococcus*, *Streptococcus*, *B. anthracis*, *B. typhosus* and *Spirilla*. Generally the entries for zoological and botanical types are under the common name; but details of the classification and common species are also supplied, and in some cases information concerning physiology and origin is also included. Treatment of the chemical elements is extensive, and details are given of the atomic number, atomic weight, common isotopes, occurrence and the more generally known compounds of that element. Included in the appendixes are lists of the chemical elements and also British, American and Continental weights and measures.

Even though the present pace of development in science and technology is likely to make it impossible for any general reference book to be completely up to date, such terms as 'fall-out', 'radiocarbon dating', 'computer', 'rocketry', 'sputnik' appear, but not 'laser', 'maser', 'chromatography' or 'Van Allen belt'. However, it is good to be reminded that the Leyden jar was invented at the University of Leyden in 1745 "for storing electric charge, consisting of a glass jar coated inside and outside with tinfoil, the electric energy being stored in the glass dielectric (non-conducting substance) between the tinfoil electrodes"; that Birkbeck College was " . . . formerly the Birkbeck Mechanics' Institution, founded 1824 by Dr. George Birkbeck (1776–1841), a physician and professor of natural philosophy"; that Uranus is "The 7th of the major planets, farthest from the sun except Neptune and Pluto; discovered in 1781 by Sir W. Herschel . . .". From these examples it can be seen that the *Oxford Illustrated Dictionary* goes much farther than dealing with words and things. In fact it also deals with famous people, the names of important places and events—the Clarendon Press is to be congratulated for extending the services of the *Dictionary* to such ends. It is inevitable that there should be some omissions, but it is to be regretted that, among the scientists, while Dalton, Fleming, Banting, Ross, Curie, Bohr, Raman, Rayleigh and Röntgen (to mention but a few) have been included, Leeuwenhoek, Rutherford and Thomson (J. J.) have been omitted.

The *Oxford Illustrated Dictionary* goes far to meet a need that has developed during the past half-century and still remains within the financial reach of the average individual. The layman has now only himself to blame if he remains ill-informed of the trends in world science, for whereas before he could cry out that he could not understand the language of the scientist, he now at least has a means to help him interpret it. At 50*s*. the *Oxford Illustrated Dictionary* should find a place on all shelves of reference books.

CONCRETE

Concrete

Properties and Manufacture. By T. N. W. Akroyd. Pp. vii + 336. (London and New York: Pergamon Press, 1962.) 50*s*. net.

THERE is no doubt whatever that concrete holds a very high rank among building materials. In the past concrete was regarded as a useful but cheap substitute for other materials, and before the introduction of the now well-known and fundamental water–cement ratio law first introduced by Abrams, the requirements for good concrete were not fully understood or appreciated. Consequently concreting was often carried out in a more or less haphazard way and generally by unskilled labour.

To-day, the design and control of concrete have become specialized activities founded on principles which are becoming so well established that the production of inferior concrete is now almost inexcusable. This does not mean that concrete is a complex science involving the use of intricate formulæ and complicated procedure; on the contrary, in spite of the confusion of literature on the subject, it is a fairly straightforward and practical art.

With a thorough understanding of some basic principles, the observation of a few fundamental and often common-sense rules, and the exercise of certain reasonable precautions, the production of high-quality concrete becomes a relatively simple task.

There are many excellent books available on the subject of concrete, but the first impression given by Mr. Akroyd's book is that he has achieved a good balance between theory and practice. The book is well set out in a logical sequence, and although in his preface the author indicates that it is intended for students and graduate engineers, I am quite certain that this book will find a very much wider range of reader.

The opening chapter provides some concise and useful information on the properties of concrete and this is followed by a rather lengthy but important chapter dealing with the materials used for concrete manufacture. The chapter on mix design sets out some useful examples based on recognized methods. The chapter on concrete manufacture: handling and batching of materials, mixing and placing, compacting and curing, is most informative and always keeps the practical aspect well in mind. The short chapter on quality control is adequate for the purpose of introducing a statistical treatment of strength test results, and in again reminding the reader of the importance of good workmen and efficient plant. The remaining chapters dealing with resistance to deterioration, surface treatment, and special concrete are based on reliable sources of information.

The provision of a general index and a list of references after each chapter is extremely useful.

To summarize, I think this book will be very helpful not only to students and graduate engineers but to other concrete workers. I compliment the author on producing such a splendid balance between theory and practice. A. J. NEWMAN

ENTOMOLOGY AT HIGH ALTITUDES

Introduction to High Altitude Entomology

Insect Life Above the Timber-line in the North-West Himalaya. By Dr. M. S. Mani. Pp. xix+302+10 plates. (London: Methuen and Co., Ltd., 1962.) 42*s*. net.

PROF. M. S. MANI of Agra University has led a number of expeditions to the Himalaya and has found, in what at first appears to be an inhospitable expanse of snow or wind-swept rock at heights of 3,500–5,000 m, a surprisingly rich insect fauna.

The most conspicuous insects are the big alpine butterflies like *Papilio machaon* and the many species of *Parnassius* which feed on the bright flowers of the short alpine summer. Their larvæ take shelter in rock crevices and feed on the low herbage. A few plant-feeding bugs and beetles are also dependent on these plants for food.

Readers unfamiliar with these places will be surprised to hear that the most numerous insects are scavenging Carabid and Staphylinid beetles, springtails and earwigs which are especially numerous in rock crevices near the melt line of the snow.

These are not so much dependent on the local plants for food as on the vegetable debris, pollen and insects originating in the subtropical plains to the south carried on the high air currents and deposited in cold storage on the snow-fields and glaciers. Careful watch gave a figure of two insects deposited per sq. m per min. At times the snow was littered with the corpses of flies, moths and aphids, and occasionally migrating swarms of butterflies were overtaken by bad weather and brought down.

As the snow-fields melt in summer, their surfaces and edges provide a rich harvest of preserved food which is taken by the active scavengers.

Another significant source of food is provided by the migrating ladybirds and other insects which form great aggregations at heights of over 4,000 m and return to lower levels after diapause. These are eaten by birds and even bears. The glacier snouts also disgorge in the short summer their accretions of food which at least partly explains the richness of the fauna of the torrents the water of which abounds with early stages of mayflies, stone flies, and countless fly larvæ, many of which are filter feeders.

The fauna of the mountain sides is greatly influenced by aspect. North and south faces are characterized by different groups of species. The slopes remain very barren except where melt water or snow-fields are adjacent. The animals swarm under the rocks which are warmed by the Sun. Only a few centimetres down in crevices temperatures of 10°–25° C and high humidities may be available for long periods, while outside it is very cold and dry. Insects of the north slopes cannot find these hot-house conditions, but many of them can maintain activity close to freezing point or even at −10° C. Collembola may become so numerous and active on snow as to impart a sooty appearance to the snow-fields.

This book is in the nature of an interim report. Perhaps three-quarters of the insects caught have as yet not been named beyond the genus (the butterflies and a few groups of beetles being the only groups easily named to species). Doubtless there are many new species in the collections still to be named, and as more and more groups are worked out in the various museums many curious new facts of distribution and ecology will emerge.

Zoologists who have tended to equate the mountain flora and fauna in the tropical zones with the tundra of the far north will find the broad generalizations of this book very stimulating. It serves to emphasize that the mountains differ not only in the physical attributes of the environment such as the relative constancy of day-length, but in the amount of nutriment derived from the richer environments close by.

The book is attractively illustrated by photographs, some of which are in colour, and by many clear line drawings and diagrams. There is a detailed bibliography and a good index. G. C. VARLEY

SPECULATIVE IMMUNOLOGY: NEW MAPS FOR OLD

The Integrity of the Body

A Discussion of Modern Immunological Ideas. By Sir MacFarlane Burnet. (Harvard Books in Biology No. 3.) (Cambridge, Mass.: Harvard University Press and London: Oxford University Press, 1962.) Pp. vi+189. 30*s*.

SIR MACFARLANE BURNET is at once the elder statesman and the *enfant terrible* of immunology. No one knows better than he how to assume an imposing air of magisterial authority while cutting the most outrageous capers.

His latest book, *The Integrity of the Body*, is a new triumph for his special blend of magniloquence and mischief. The general scientific reader, if unprotected against the exhilaration of Burnet's style by any special knowledge of the topics discussed, is assured of having the time of his life. The professional immunologist, if he is worth his salt, may derive a benefit of a different kind: in all likelihood he will be goaded into fresh experimental attempts to refute, once and for all, this irrepressible sage.

The first four chapters cover in a clear and breezy style the elementary background of disease-resistance, antibodies, blood groups and hypersensitivity reactions. Chapter 5, which is about cells, suffers from a misfortune of timing. Important recent advances made by J. L. Gowans and others in charting the life-histories and metamorphoses of the cells responsible for immune reactions were made public after Burnet's book went to press, and the same is true of much of our new knowledge of the immunological role of the thymus gland. A similar mishap, which overtakes the following chapter on "Self-recognition", reveals the unwisdom of dogmatism in scientific exposition. The chapter contains among other things a gallant attempt to expound the principles by which protein primary structure can be coded in the base-sequence of the DNA molecule. The description appears, however, to be based on the now disproved 'commaless code' of Crick, Griffith and Orgel. The account of immunological tolerance given in this same chapter constitutes a more serious case of the same nature—more serious because it is a topic on which Burnet may claim a special title to have his views heard. The statements that "tolerance must be induced in the first day of life or before birth" and "no animal can produce antibody till it is at least 14 days old" are both incorrect. First, states of immunological unresponsiveness which are indistinguishable from tolerance can be induced in adult mice. Secondly, in sheep and opossums antibody-formation has been successfully elicited in embryonic life. These facts are exceedingly damaging to Burnet's own particular theories, according to which tolerance results from confrontation with antigen during a special 'self-recognition' process supposed to occur at a critical phase of ontogeny. Indeed, they suggest a quite different interpretation of tolerance in terms of the well-known phenomenon of 'immunological paralysis' first demonstrated in adult mice by Felton. Yet Burnet omits from this book all mention of Felton's work.

In the next chapter, "The Clonal Selection Theory of Immunity", Burnet vaults astride his own special hobby-horse, which soon, Pegasus-like, carries him far away from earthbound mortals. In the remainder of the book a few interesting descents to Earth are made, notably in the discussion of auto-immune diseases. He remarks, for example, on the occurrence of these diseases in patients suffering from congenital agammaglobulinæmia, and makes the important point: "Since in agammaglobulinæma antibody in the blood is never produced, we can feel sure that rheumatoid arthritis and the other so-called auto-immune diseases are not primarily due to anomalous antibody production, even though it may be easy to show in most cases that abnormal antibodies are present." But in the final chapter, entitled "The Deeper Problems", contact with established fact ceases, for we have come to the peroration. This takes the form of a plea for Burnet's present ideas concerning the evolution of immunological systems. He sees their function not primarily as that of a defence force against microbial invasion; rather they constitute a sort of secret police for the liquidation of deviationist (for example, cancerous) cellular elements which may arise from within by somatic mutation. This is, Burnet admits, "no more than a hypothesis. But it is in accord with the whole trend of modern immunology that it should be true". This statement has surprise value, if nothing else, and the book concludes on a lively note.

DONALD MICHIE

ADVANCES IN STEREOTAXIS

A Stereotaxic Atlas of the Cat Brain

By Ray S. Snider and William T. Niemer. Pp. 132. (Chicago and London: University of Chicago Press, 1961.) 95*s*.

A Stereotaxic Atlas of the Monkey Brain (Macaca Mulatta)

By Ray S. Snider and John C. Lee. Pp. 132. (Chicago and London: University of Chicago Press, 1961.) 95*s*.

THE brain is one of the most inaccessible of the body's tissues and in both the clinical and experimental fields means have been sought of gaining access, without excessive trauma, to its deeper parts. An early attempt to take advantage of the reasonably close relationship between the bony landmarks of the skull and intra-cranial structures was made by R. A. Clarke in 1908, who built the first stereotaxic instrument based on rectangular co-ordinates for use by Sir Victor Horsley in the study of cerebellar function in the monkey. The potential of this technique for the localization and study of discrete cerebral structures was overlooked until 1936, when the late S. W. Ranson stimulated a renewal of interest in a tool which has since proved invaluable to the neuro-anatomist, neurophysiologist, neuro-pharmacologist and neurosurgeon. Though originally designed for the positioning of circumscribed electrolytic lesions the stereotaxic method has more recently been used for the administration of focused ultrasound and ionizing radiations and for the study of changes in neuronal activity following the electrophoretic application of drugs.

Several atlases have been designed for studying, by stereotaxic methods, such species as the cat, rat, rabbit, dog and monkey, and among these the present volumes are quite the most complete and sophisticated to date. Presentation is in the form of paired photomicrographs of beautifully prepared coronal sections of the brain extending, at intervals of 0·5 mm, from the anterior corpus striatum to the anterior limit of the nucleus gracilis. The plates are large in size and of exceptional clarity. One of each pair is stained and labelled to show nuclear and the other to show fascicular structures, and co-ordinates measured from the sagittal and inter-aural planes are clearly marked.

These atlases represent a considerable advance over their predecessors, which have concentrated mainly on the diencephalon, and the inclusion of the co-ordinates of medullary structures will be of considerable value to students of the reticular formation of the brain stem. One may perhaps regret that, in work of this quality, no attempt has been made to provide a guide to the identification of nuclei in terms of their finer anatomy other than to refer the reader to "original research articles in the various anatomical journals" which incidentally are not contained in the bibliography; and since the authors direct attention to the dangers of fouling the tentorium cerebelli with the advancing electrode tip it would have been helpful had, at the same time, the co-ordinates of this structure been illustrated on the appropriate sections. A further, and surprising, omission is a failure to define the horizontal plane of orientation in terms of extra-cranial structures—a feature which may prove disadvantageous to users of non-standard stereotaxic instruments. But such criticisms are small by comparison with the value of these two companion volumes whose appearance will be welcomed by all working with the cat and the monkey whether or not they are concerned with stereotaxic methods.

THE GIFTED CHILD

The Year Book of Education 1962

The Gifted Child. Joint Editors, Prof. George Z. F. Bereday and Prof. J. A. Lauwerys. Pp. xiv+541. (Published in Association with the University of London Institute of Education and Teachers College, Columbia University, New York, by London: Evans Brothers, Ltd., Twenty-fourth edition, 1962.) 63*s*.

THIS book contains sufficient educational dynamite to turn the education committee of every local education authority into a fratricidal bear garden. For there is war—and war to the death—between the views of Sir Cyril Burt and those of Prof. J. P. Guilford of the University of Southern California.

Sir Cyril Burt, the convinced Platonist, in a fine historical account of the development of the intelligence quotient (I.Q.) idolatry which some of us consider is slowly destroying the educative value of all conventional 'education', tells us that the gifted child, as defined by him and those who share his views, is "as a rule, taller, stronger and healthier than the average. He is on the whole free from abnormalities of whatever kind, physical, intellectual, emotional and nervous. Until they begin to specialize, most gifted children are gifted all round". They are, indeed, the very people whom Plato would have set aside to provide the upholders and preservers of the changeless State, and also, of course, of the small core of philosopher-kings. They are those whom Samuel Smiles would also have approved of most.

In contrast take this paragraph from Prof. Guilford's very important article. "And which children should be regarded as gifted? The current answer, at least in many places, is the student with a high I.Q. and with high grades (the two indicators usually strongly correlated). Such children may be those who please their teachers most because they learn more rapidly under conditions that call for uniformity of thinking and acting within a group. The more creative child, who may be higher in divergent thinking abilities and not so high in cognitive abilities emphasized in present tests and examinations, may be a source of annoyance and not recognized as gifted. And how many children who are potential composers or artists, who are very high in concrete intelligence but not so high in academic intelligence, are missed when the 'gifted child' is selected."

It was worth publishing this fascinating volume even if only to make the epoch-making researches of Prof. Guilford known to a wide non-specialist world public, and his article on parametry and categories of talent is doubtless the most exciting in this book. The wide researches carried out under his guidance on young adults, and supported by funds from the U.S. Office of Naval Research and the U.S. Office of Education, have established that there are already fifty-five different primary abilities which have been recognized; there are probably many more. For the past thirty years thousands of educationists and millions of ordinary people, believing that there is more faith in honest doubt, have found it hard to accept the view that the I.Q. test could really be adequate as a measure of human intellectual endowment. But we have been unable, through lack of the necessary research funds and research workers, to prove this scientifically. But thanks to Prof. Guilford and the U.S. Office of Naval Research we can now say with Prof. E. Paul Torrance, who writes on "Measurement and Development of the Creative Thinking Abilities", that educators "are beginning to recognize that the human mind is far more complex than can be inferred from present-day methods of identifying 'the gifted', and, in particular, that traditional measures of I.Q. tap only a few of man's thinking abilities". Indeed, Torrance is able to affirm "if present methods of identifying talent had been applied they would have eliminated many of the great men of the past".

The tragedy for England and Wales at this time is that the development of "Beloe" examinations in all secondary modern schools and streams is going to confine education for an ever-greater percentage of our pupils within the cast-iron boundaries of the traditional academic syllabus and examination. The opportunity for the teacher to develop in every one of his pupils the peculiar and valuable endowment that nature has given him is slowly being eroded away. As Prof. Guilford states, "If each child is to be given the opportunity to make the most of his outstanding assets, those outstanding assets will have to be recognized. They cannot be recognized by the use of an I.Q. test whose coverage of that great complex of intellect is severely limited to a few qualities that have predicted grades that are also severely limited in intellectual scope".

There are forty articles in this volume and they survey the developments in the chosen field from many points of view and discuss selection procedures in many countries. Every educational thinker and educational politician should dip into it.

C. H. DOBINSON

Logic and Existence

By Prof. Martin Foss. Pp. x + 240. (New York: Philosophical Library, 1962.) 4.75 dollars.

THE author of this book writes with a deep conviction of the part which philosophy has played not only in history but in present-day affairs in bringing discipline into the realm of thought. Much of what is said amounts to a strong plea for responsibility in mankind's work of ratiocination. There are two main parts, entitled "Abstraction" and "Reality". Running through the argument is a marked axiological thread, courageously facing the problem of value and what it entails. The outcome of this, as might be expected, is that a class of experiences will emerge, the members of which are individual, and, to that extent, unique. They are art, ethics and religion. Naturally, East and West have gone their separate ways, but there is no doubt that Prof. Foss perceives in a picture or a piece of music an emotional event, but subject to some measure of mathematical law. This is only to be loyal to his thesis that philosophy lives doing battle against subjective thinking. Abstraction is almost taken as a crutch to help us along uphill towards metaphysics.

All this is admirable, if slightly unfashionable. What would weld it together a little more convincingly might have been to introduce the '*Gestalt*-concept': then, with the help of the law of *prägnanz*, a minimal energy is shown to be implicit (akin to potential theory) in works of art. This method—if teleological considerations are permitted—could allow for (almost demand) the stark element of sacrifice which the writer's 'sacramental' principle requires.

F. I. G. Rawlins

Quantitative Chemical Analysis and Inorganic Preparations

By Dr. R. M. Caven. Second edition. Revised by Dr. A. B. Crawford and W. A. Alexander. Pp. vi + 428. (London and Glasgow: Blackie and Son, Ltd., 1962.) 35*s.* net.

THIS book, first published in 1923, and afterwards reprinted twenty times, now appears in a second revised edition. Intended as a teaching manual, it is divided into two sections—Part 1 at the elementary level, and Part 2 at a more advanced level for college and university students, the general effect, enhanced by some duplication of chapter headings, being one of two text-books in one binding. Part 1 is described as covering the preparation of inorganic salts and simple exercises in gravimetric and volumetric analysis, and Part 2, volumetric analysis, gravimetric separations, analysis of minerals and alloys, and preparation of inorganic compounds.

The treatment is on conventional lines and, on the analytical side, is intended to give the student a thorough grounding in classical principles, while the preparations ensure practice in other than purely analytical manipulations. Recent developments in analytical chemistry are represented in Part 2 by a chapter on chelatometric titrations, with six exercises in the use of ethylenediaminetetra-acetic acid, and one of three pages on some applications of ion exchange resin, with two practical examples. The chapter on colorimetric analysis is limited to three determinations by the Nessler technique. In view of the widespread use of the simpler colorimetric instruments and the growing importance of colorimetric methods of analysis, some amplification here might seem desirable, but the present authors state their intention not to include instrumental methods, which, in their opinion, are adequately dealt with elsewhere and which in any event provide very little opportunity for the student to acquire the basic analytical skills.

The style and manner of the original text have to a large extent been retained in the new edition, with the emphasis on readability as opposed to the almost peremptory conciseness of some present-day text-book writing.

G. A. Sergeant

Advances in Clinical Chemistry

Vol. 4. Edited by Harry Sobotka and C. P. Stewart. Pp. xiv + 378. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1961.) 86*s.*

AS in earlier volumes of this series, the contents of Volume 4 can be sharply divided into two classes—those dealing with methodology and those dealing with chemical substances or clinical conditions.

The sections on methodology cover flame photometry by I. MacIntyre, immunoelectrophoresis by C. Wunderly and ultramicro methods by van Haga and de Wael, and are given with a wealth of detail and an abundance of useful diagrams.

The other sections include a miscellaneous collection of topics ripe for review, such as the non-glucose melliturias by J. B. Sidbury, jun., organic acids in blood and urine by J. and R. Nordmann, ascorbic acid in man and animals by W. E. Knox and M. N. D. Goswami and parathyroid function by B. E. C. Nordin. The high standard of presentation which one is now accustomed to in this series has been maintained throughout.

J. N. Davidson

Advances in Spectroscopy

Vol. 2. Edited by Dr. H. W. Thompson. Pp. xi + 483. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1961.) 13 dollars.

THIS is the second volume of a collection of short surveys of developments in all the important branches of spectroscopy over the past few years. These are intended to be easily read and comprehended by spectroscopists working in other fields. The present volume contains nine such surveys on atomic absorption, flame emission, X-ray analysis, nuclear magnetic resonance, infra-red absorption of crystals and of micro-organisms, refraction of gases in the infra-red, ultra-violet absorption of proteins, and the theory of molecular energy levels. Each of these articles is an up-to-date and fairly comprehensive review by an authority in that particular field, although in some cases much of the subject-matter has been recently reviewed in other publications.

In order to cover the vast range of practical and theoretical topics embraced by the term 'spectroscopy', many volumes will be needed to complete this work, and with the present spacing of two years between the volumes, it may never be completed. While there exists a great need for surveys of this sort, it is surely necessary for each volume to be composed of a greater number of shorter articles confined to advances in the preceding two or three years and with a minimum of introductory material.

With these general reservations, this volume is authoritative and well produced, and should certainly be read by every spectroscopist who wishes to keep a grasp on the subject as a whole.

A. Knowles

CONSERVATION AND OUTDOOR RECREATION IN THE UNITED STATES

By J. J. MACGREGOR

Department of Forestry, University of Oxford

White House Conference on Conservation

EVEN the most casual observer of the American scene is aware of the present concern over the use of the nation's resources; nor are the broad reasons for the disquiet difficult to account for. In many ways the United States is an under-developed region of the world: its population has been, and is, low in relation to its extensive and very valuable natural resources, and this at times has given the appearance of wastefulness and of callousness over their usage. There was lavish use of land, of forests and of water under industrialization as the frontiers were pushed farther west. To-day there are no frontiers in this sense and the nation is taking stock of the way in which the "free gifts of Nature" have been, and are being, used. In an era when there was little local or regional planning, private enterprise had free-planning for exploitation of the local environment to suit its own particular, financial gain—this appears to have been a feature of early industrialization in most countries. Even if others paused to count the social cost there was little that could be done to stop the malpractices which opportunities for quick profits often engendered. Now it is different, and there is a growing recognition that unthinking exploitation must be countered as the social cost of soil erosion, water pollution, air pollution, silting up of reservoir and river basins, destruction of amenities and so on, is being added up. The rules of the game are being clarified. A distinction is being made between something which can be mined and eventually exhausted and one which is a renewable resource and can exist or be improved more or less in perpetuity if given good management. The antithesis of conservation is the depletion of natural resources.

Symptomatic of the present concern is the weight given by the Administration to conservation. In March of this year President Kennedy sent to Congress a message which underlined the urgency of conservation policy. The growths of population and of industrial activity and productivity implied greater demand and opportunities for leisure. While much of the affluence of the country was attributable to the abundance of many physical resources, these were not inexhaustible and did not automatically replenish themselves. Conservation policies implied wise use of the natural environment—an approach which could be described as the highest form of thrift. Special effort would be necessary to deal with the problems of air, water and land; fuels, energy and minerals; soils, forestry and forage; fish and wild-life and human resources. In his message, the President reminded Congress of his suggestions at the start of his administration and referred to the "heartening progress" made to counter water pollution and flooding; to the development in water resources partly through the saline-water programme; to the establishment of recreation areas; to long-term plans for wild-life and forestry and so on.

This message gives a very useful clue to the range and scope of a conservation policy within the American setting since it reviewed progress and made recommendations under each of the main heads in the following order: outdoor recreation (see next heading); water; public lands; soil; watershed and range resources; timber; power; and research and technology. Proposals for the formation of an Outdoor Recreation Advisory Council, a Bureau of Outdoor Recreation and programmes of 'matching' grants to help individual States to provide facilities are measures of their present importance. In January the Outdoor Recreation Resources Review Commission made its report after intensive investigation and its recommendations included the advisory council and the bureau which are now urged as part of national policy.

Other proposals emanating from the President's message were the creation of a land conservation fund; the setting up of new national parks; new legislation to plan water resources and to deal with land sales; amendment of the Watershed Protection and Flood Protection Act; development of national multiple-purpose forest roads; and the listing of a great variety of problems for research.

To maintain the momentum of the present activities outlined in his message to Congress, the President mentioned that he would convene a White House Conference on Conservation in order "to provide an opportunity for the exchange of further ideas—and to permit those who have dedicated their efforts to the principles of conservation to participate in evaluating the progress that has been made—and to seek the best possible advice in presenting what must be done in the future".

When the Conference was duly convened, towards the end of May, I was able to attend and learnt that it was the first White House Conference since Theodore Roosevelt had called a meeting of Governors for the same purpose in 1908. On this occasion it appeared that most of the speakers in the two-day programme were representatives of the executive or legislatives of Federal and State Departments. Appropriately enough the Conference began with an address from Mr. W. W. Heller, the chairman of the Council of Economic Advisers. He made it clear that economic considerations had come within the purview of the Conference theme of "Conservation for the 'Sixties" and exposed the futility of having large national incomes if, in the process of achieving them, the foundations were undermined. Subsequent speakers made different approaches to the same threat: the Secretary of the Interior, Mr. S. L. Udall, emphasized the limitations of the former piecemeal approach and that in the new efforts it was necessary to see things in perspective and to look at the resources as a whole rather than as watertight, individual compartments. Conflicts between diehard advocates should be avoided if conservationists were to be effective politically; simple solutions in complex matters were inappropriate and would lead to lost opportunities in a period of 'last chances'.

The Secretary of Agriculture, Mr. O. L. Freeman, dealt with the relationship of Government aid and land-use adjustments. He felt that it would be possible to balance the productivity of farming with the use of land and water resources to meet the growing demand from an expanding urban population—to reconcile food plenty with a recreation shortage. Clearly, agricultural and conservation policies had to be compatible and this object could be found in the conservation principles and multiple use of private lands.

Other speakers directed attention to significant tendencies or proposals. The encroachment by urban expansion was about one million acres per annum—the urban area had doubled in the past decade. The Army's Corps of Engineers takes a very active part in the civil development of the country and was carrying out a billion-dollar-a-year conservation mission in river basins, coastal harbours and the Great Lakes. With water resources it was not only essential to have adequate supplies for the future but also that they should be effectively sited and where wanted. The Senate Select Committee on National Water Resources had estimated that by 1980 more than 400 million acre-ft. of extra reservoir space would be required. In addition to the actual supply of water, reservoirs have multiple-purpose functions: from river regulation, storage of flood-water for release in dry seasons; recreation; fishing and wildlife. The increased opportunities for power production and for use by shipping were other features of water storage policy. This multi-purpose function is, indeed, one of the main lessons which the development of the Tennessee Valley Authority has effectively demonstrated.

The conservation movement undoubtedly has adherents who accept rather uncritically some of its limitations as a political panacea. Unlike those who take the economic view they tend to overlook the problems associated with the institutional constraints, evaluation and uncertainty. Economists realize that a nation has to make a choice over allocations of resources and over time. Conservation is only one choice which may merely mean that posterity's inheritance will be altered from capital goods to natural products.

To many who regard conservation as a rather vague or complex concept it is probable that few original ideas emerged from the Conference although those who are aware of some of its implications would welcome the publicity given to a subject which they regard as topical and urgent. At least the supporters of the movement can take comfort from the fact that some of the ideas of the conservationist are finding their way into legislation.

At the end of the Conference President Kennedy spoke of the need to apply scientific discovery to conservation. As an example he believed that the first country which could produce cheap and abundant fresh water from the sea would have even greater advantages than the one that would be first to conquer space and, as he put it: "Harnessing science to conservation is going to be the big accomplishment of our day".

Outdoor Recreation for America

At present very great interest is being shown in outdoor recreation in the United States. This is apparent, for example, from President Kennedy's message to Congress at the beginning of March 1962, where, indeed, recreation appears first in the order of proposals and recommendations made to Congress. It was in this message that the President intimated that he was going to have the White House Conference on Conservation because he wanted "to provide an opportunity for the exchange of further ideas—and to permit those who have dedicated their efforts to the principles of conservation to participate in evaluating the progress that has been made—and to seek the best possible advice in prescribing what must be done in the future".

Some of President Kennedy's proposals were based on recommendations of the Report by the Outdoor Recreation Resources Review Commission which was submitted at the end of January*. The Report is a well-documented and comprehensive survey of 246 pages, including the Commission's terms of reference, which were set out as follows:

"That in order to preserve, develop and assure accessibility to all American people of present and future generations such quality and quantity of outdoor recreation resources as will be necessary and desirable for individual enjoyment, and to assure the spiritual, cultural and physical benefits that such outdoor recreation provides; in order to inventory and evaluate the outdoor recreation resources and opportunities of the Nation, to determine the types and location of such resources and opportunities which will be required by present and future generations; and in order to make comprehensive information and recommendations leading to these goals available to the President, the Congress and the individual States and Territories, there is hereby authorized and created a bipartisan Outdoor Recreation Resources Review Commission".

After a review of the outdoor recreation resources, the Report measures present and likely demands on them over the next forty years, and recommends actions to ensure their availability to all Americans of present and future generations. In the past Americans had "responded to the need for protecting their unparalleled outdoor heritage" and it was now necessary to follow their lead at a time when the country was growing faster and becoming even more urban and requiring a new scale of effort and ingenuity. The Commission believed that a great deal could be accomplished by well-directed and vigorous action and by co-ordinated public and private activity and investment. The Commission's investigation was greatly assisted by the individual States some twenty Federal agencies and their own advisory council.

The main parts of the Report are concerned with an introduction with summary of recommendations. Part I, "The Facts", has five chapters headed: the outdoors in American life; the demand; the supply; the economics; and the needs. Part 2, "Recommendations", has nine chapters: guidelines for management; organizing for the task; Federal policies and programs; the key role of State Governments; recreation for metropolitan America; the private role; financing outdoor recreation; water—a key element; and research—an essential foundation. The appendixes cover the Act, State contact officers, the Commission's study reports—including 27 useful abstracts, contractors, consultants and statistical tables.

To measure present resources for outdoor recreation an inventory of all the non-urban public recreation areas which number more than 24,000 for the country as a whole and more than 100 items were analysed for 5,000 of the larger areas in order to evaluate existing uses, capacity and potential for development. Special studies were made to cover wilderness, water recreation, hunting and fishing, the densely populated north-east and sparsely populated Alaska. In order to estimate the existing and future pressure on the resources, a series of studies was made on the demand for recreation and a National Recreation Survey involving about 16,000 people was carried out for the Commission by the Bureau of the Census. This survey was also supplemented by studies by the Commission on the effects on outdoor recreation of present and prospective changes—sectionally and nationally—in personal income, population, leisure time and in travel facilities. A State contact officer, at the request of the Commission, was appointed by each Governor so that all requests could be channelled to him. They were usually the head of the State conservation, recreation, fish and game, or planning agency and played a major part in the inventory; in other studies they provided financial, legal and administrative data. The Federal Agencies in Washington and their field officers put their valuable experience before the Commission and also provided specific data on their programmes. In most of the studies the Commission started off by consulting these agencies to see what information was already available. Needless to say, the Commission was helped by a considerable staff which was recruited at the end of 1958. Apart from the editorial, administrative, secretarial and clerical staffs there were specialists on policy and programme, inventory and evaluation, forecasts and economics.

---

* *Outdoor Recreation for America.* A Report to the President and to the Congress by the Outdoor Recreation Resources Review Commission. January 1962. (Washington, D.C.).

Under a heading on "Some Findings of the Study" the following conclusions were listed about outdoor recreation: the simple activities are the most popular; outdoor opportunities are most urgently needed near metropolitan areas; across the country, considerable land is now available for outdoor recreation, but it does not effectively meet the need; money is needed; outdoor recreation is often compatible with other resource uses; water is a focal point; it brings about economic benefits; it is a major leisure-time activity and it is growing in importance, and more needs to be known about its values.

Recommendations. In developing its recommendations the Commission was greatly assisted by its own Advisory Council, composed of 25 individuals representing other rural interests as well as recreation and conservation and also top-level representatives of 15 Federal agencies. The State contact officers also had an important influence in shaping the decisions. Many of the recommendations are general but some are specific.

A national outdoor recreational policy. "It shall be the national policy, through the conservation and wise use of resources, to preserve, develop and make accessible to all American people such quantity and quality of outdoor recreation as will be necessary and desirable for individual enjoyment and to assure the physical, cultural, and spiritual benefits of outdoor recreation.

"Implementation of this policy will require the co-operative participation of all levels of government and private enterprise. In some aspects, the government responsibility is greater; in others, private initiative is better equipped to do the job."

Details are given of what the Federal Governments and the State's functions should be, and what the various interests should do.

Guidelines for Management. All the agencies administering outdoor recreation, both public and private, are urged to adopt a system of classifying recreation lands designed to make the best possible use of available resources in the light of needs. The following system of classification is proposed: Class I, high-density recreation areas; Class II, general outdoor recreation areas; Class III, natural environment areas; Class IV, unique natural areas; Class V, primitive areas; Class VI, historical and cultural sites.

Expansion, modification and Intensification of present programmes. Under the head of "Planning, Acquisition, Protection and Access" more than a dozen detailed suggestions are made, a central State agency should be set up to develop long-range plans; local Governments should be more active in supplying the need; inter-State arrangements should be systematic; continuing research, acquisition of more access to water areas, including reservoirs, establishment of certain primitive areas as 'wilderness', certain rivers of unusual scientific, æsthetic and recreation value should be allowed to remain in their free natural state, educational programmes should be intensified; etc.

Several suggestions are also made under the heading of "Promoting Recreation Values in Related Fields" and these include suggestions for obtaining recreational benefits from other major activities such as water developments, pollution control, flood-plain zoning, highway reconstruction, watershed and other agricultural conservation programmes, State encouragement of public use of private lands, for example, by leases for hunting, fishing, scenic easements and landowners' protection.

The final heading in this section is "Meeting the Costs" and the suggestions here are that all levels of Government must provide continuing and adequate funds, mostly at increased levels, use of bonds, season user fees, dedicated funds, and use of uncollected refunds of petrol taxes, easements, zoning, cluster developments, and open land tax policies to supplement the supply of recreation opportunities. Public agencies should stimulate desirable gifts of land and money from private sources, and private enterprise should be encouraged, and concessions to provide facilities.

A Bureau of Outdoor Recreation. This Bureau should be established in the Department of the Interior and would have over-all responsibility for leadership of a national effort by co-ordinating the various Federal programmes and assisting other levels of Government to meet the demands for outdoor recreation, but it would not manage any land, which would remain with the existing managerial agencies. The main functions foreseen for the Bureau were classified as follows: (1) Co-ordinate the recreation activities of the more than 20 Federal agencies the activities of which affect outdoor recreation; (2) Assist State and local Governments with technical aid in planning and administration, including the development of standards for personnel, procedures and operations; (3) Administer a grants-in-aid programme to States for planning and for development and acquisition of needed areas; (4) Act as a clearing-house for information and guide, stimulate, and sponsor research as needed; (5) Encourage inter-State and regional co-operation, including Federal participation where necessary.

To assure that recreation policy and planning receive attention at a high level and to promote interdepartmental co-ordination, there should be established a Recreation Advisory Council, consisting of the Secretaries of Interior, Agriculture and Defense, with the Secretary of the Interior as chairman. Other agencies would be invited to participate on an *ad hoc* basis when matters affecting their interests are under consideration by the Council.

The Recreation Advisory Council would provide broad policy guidance on all matters affecting outdoor recreation activities and programmes carried out by the Bureau of Outdoor Recreation. The Secretary of the Interior should be required to seek such guidance in the administration of the Bureau.

Initially, the new Bureau should be staffed where possible by transfer of experienced personnel from existing Federal agencies, and it would have regional offices.

A Research Advisory Committee consisting of professional people from Government, academic life and private business should be established to advise the Bureau on its research activities.

It is urged that each State designate a focal point within its governmental structure to work with the Bureau. This focal point, perhaps one of the existing State agencies, could also serve to co-ordinate State recreation planning and activities and be responsible for a comprehensive State outdoor recreation plan.

A grants-in-aid programme. This would be a Federal Programme and would be set out to stimulate and assist the individual States in meeting the demands for outdoor recreation and would be administered and reviewed by the proposed Bureau of Outdoor Recreation. The programme itself would be supplementary to the provisions of recent legislation. The level of grants envisaged were up to 75 per cent of total cost for planning in the first year and would be reduced later; for acquisition and development the grants could be up to 40 per cent or to 50 per cent where the acquisition was part of an inter-State plan. The criteria for giving priorities in grants would be based on State population, area, needs and amount of Federal land and Federal recreation programmes in the State and region. This programme of grants-in-aid, it was recommended, should be supplemented by loans to the States in order to help where matching funds were not available and where the need was urgent, and where the grants-in-aid funds were not adequate.

The main body of the Report provides considerable elaboration under each of the main chapter headings although some of them are less fully explored than others. For example, no very deep assessment has been made of the economic aspects, and it is not thus very surprising that in the research recommendations the economic assessment should have strong support. Some of the statistical data are presented in a more palatable form for those who prefer visual aids, and these help to stress what is most significant in the individual chapters: one of the regional maps directs attention to the position that whereas most of the recreation is in the west most of the people are not, and this is particularly true of Federal lands. Forest agencies at all levels of Government manage the greatest number of acres but a small percentage of the total number of areas. Most of the acreage is in large tracts and conversely most of the units are small—less than 40 acres. One of the map diagrams illustrates the variety of ways that recreation can be built into an environment; another shows examples of each of the six classified recreation areas and there are associated photographs indicating the great variety of activity or type of interest. There is also a useful diagram which shows how the Federal agencies, with programmes involving some aspect of outdoor recreation, are linked to each other and to the individual Government departments; the same outline shows which agencies have major land management responsibilities and also how the proposal to have an Advisory Council and the Bureau of Outdoor Recreation are built into the Department of the Interior.

On research proposals the report distinguishes between three related but distinct categories: data collection, inventory and fact-finding; applied management research; and fundamental research. One of the most urgent needs was for more knowledge on the direct benefits derived from recreation. Public recreation facilities are not usually sold for a price, and Federal agencies and others have sought for some time to devise methods of evaluation. Some methods were described, and their limitations emphasized: these included flat rate daily charge basis, cost of travelling at various distances from the recreation area and in terms of alternate use. One of the most promising methods is based on market area surveys. One of the Commission's studies developed an analytical framework to assist in orderly planning and development of recreation facilities in order to provide a guide to the kinds of data needed to solve problems of benefit-cost analysis in outdoor recreation. A general conclusion, however, was that regardless of the technique used no single value can be assigned to the wide variety of recreation activities. The net benefits of recreation could only be judged on the merits of the case and in the present state of knowledge the best procedure for making judgments appeared to be based on a detailed analysis. One of the main functions of the proposed Bureau of Outdoor Recreation would be to act as a central clearing house of information, and where there is a lack the Bureau would stimulate or sponsor appropriate investigation.

ELECTRONIC DELOCALIZATION AND BIOCHEMICAL EVOLUTION

By PROF. BERNARD PULLMAN and DR. ALBERTE PULLMAN

Institut de Biologie Physico-Chimique, Université de Paris,
13 rue Pierre Curie

IN one of his recent books Szent-Györgyi[1] states that "research is to see what everybody has seen and think what nobody has thought". When a quantum chemist, used to thinking in terms of σ- and π-electrons, localized and delocalized molecular orbitals, saturated and conjugated compounds, comes for the first time in contact with biochemistry he is bound to be attracted by aspects of this science which escaped the attention of other types of investigators. What struck us as one essential, although apparently hitherto unnoticed, aspect of biochemistry is the fact that all the essential biomolecules which are related to, or perform, the fundamental functions of the living matter are constituted of completely, or at least partially, conjugated (resonating) systems, rich in delocalized π-electrons[2,3].

Thus, the three fundamental structural units of the cell are undoubtedly the nucleic acids, the proteins, and the energy-rich phosphates. Now, the most significant constituents of the nucleic acids which impose on them their biological personality and determine their specific functions are the purine and pyrimidine bases, which are conjugated heterocycles. In the biologically important energy-rich phosphates, the mobile electrons of the phosphoryl group always interact either with those of another similar phosphoryl group (the case of the pyrophosphates, adenosinetri- and adenosinedi-phosphate) or with those of a π-electron-possessing organic radical (the case of the guanidino-, acyl- and enol-phosphates). No such interaction is present in the energy-poor phosphates, in which the phosphoryl group is attached to a saturated carbon. As to the proteins, although they appear, at first sight, to be essentially non-resonating entities containing only isolated conjugated fragments (each peptide link is such a fragment[4]), there is a number of indications that their over-all supramolecular structure involves (as foreseen by Szent-Györgyi[5]) some degree of general electronic delocalization[6]. This last situation arises from the fact that the peptide bonds, although separated from each other in the backbone by saturated carbons, are, however, united to each other by secondary cross-linkages, namely, hydrogen bonds. Inasmuch as these bonds may participate in electronic delocalization and transmit conjugation effects[7-9], the existence of such a network represents the possibility of an extended electronic conjugation involving the whole molecular framework of the protein.

Nucleic acids, proteins and energy-rich phosphates, although the most important representatives, are not the only conjugated constituents of the cells.

Pteridines, porphyrins, quinones, carotenoids, retinenes, melanins, etc., are other important structural components of biomolecules belonging to the same type of conjugated compounds.

Another most striking observation in the same field concerns enzymes. There are hundreds of enzymes and they are essentially proteins. However, if one excepts the hydrolytic ones, most of the enzymes exert their catalytic activity in conjunction with a coenzyme. There is only a very limited number of essential coenzymes, about twenty, and practically all of these coenzymes are conjugated organic compounds. Such is the case, in particular, with the oxidation-reduction coenzymes, DPN, TPN, FAD, FMN, the hæm prosthetic groups of the cytochromes, and the quinones. Moreover, it is also the case with the coenzymes involved in group transfer reactions: tetrahydrofolic acid, pyridoxal phosphate, thiamine pyrophosphate, vitamin B_{12}, etc.

As a matter of fact, among the fundamental organic constituents of the living cell, carbohydrates, fats, and steroids seem to be the only non-conjugated type of molecules. Among these, carbohydrates and fats represent merely the fuel for the driving of the machinery without being functional constituents of it. The steroids generally possess a π-electron section, and, anyway, seem to be in some way involved in electron transfer phenomena[10,11].

It is thus obvious that the basic manifestations of life are intimately connected with the existence of highly conjugated compounds, which for some decisive reason have been 'chosen by Nature' for being the vehicle of life.

When looking for such a reason one can scarcely think of anything else than electronic delocalization, which represents the most specific and at the same time the most important characteristic of such compounds. In what way can this outstanding feature of the resonating molecules account for their occurrence as the principal building stones of the living matter? We may distinguish at least two major factors responsible for this occurrence, related, respectively, to stability requirements and to functional advantages.

Stability

One of the major and most apparent results of electronic delocalization is the increment of stability which this delocalization confers on compounds in which it occurs. Quantitatively this increment is defined as resonance energy, and is nowadays one of the most popular concepts of quantum chemistry. Particularly strong in pentagonal and hexagonal rings it may amount in the common previously quoted biochemicals from a few tens to a few hundreds of kcal/mole (for example, it is of the order of 30–45 kcal/mole in the pyrimidines, of the order of 50–80 kcal/mole in the purines and of the order of 200 kcal/mole in the porphyrins). It represents an unexpected economy for the energy expenses in anabolic processes. Thus, for example, the *de novo* synthesis of purines from simple constituents may be considered as a series of ATP dependent synthesis of carbon–nitrogen bonds[12]. Eight such bonds are established during the formation of hypoxanthine, the first purine ring to be formed in this synthesis, and in every case but one the formation of such a bond is associated with the hydrolysis of an energy-rich bond of ATP. This represents a cost in energy for the synthesis of the purine skeleton of about 50–60 kcal/mole. The gain of resonance energy associated with this synthesis, calculated by the molecular orbital method[3], is 3,4β which with $\beta = 16$ kcal/mole represents about 55 kcal/mole and compensates thus this expenditure.

It seems natural to assume that this thermodynamic stabilization must have played a non-negligible part in the evolutionary selection of this type of molecules for biochemical processes. It is widely acknowledged to-day[13-16] that the biological evolution through the natural selection of species was preceded by a biochemical (or prebiological) evolution, a long period during which a great number of molecules and aggregates were formed, altered and destroyed and during which the molecules competed between themselves for reaction and function networks. This was the period of struggle for the survival and selection of biomolecules. Although the adaptability to the developing function was, of course, highly important it seems nevertheless that this condition must have been subordinated to the requirements of stability and that the molecules which finally gained must have been those which were the most stable and the biochemical possibilities of which must have, in fact, oriented or at least influenced the function itself.

A confirmation of this point of view may be found both in the extraordinary unity of biochemistry, the same limited number of compounds being used all over the plant and animal kingdoms and in the multiplicity of functions linked with some of the basic skeletons. This last statement may be illustrated by two striking examples.

The first one concerns the case of porphyrins. These very strongly resonance-stabilized molecules (in which four cyclic pyrroles are united by supplementary double bonds into a conjugated super-cycle) are utilized in photosynthesis, in the respiratory (electron transfer) enzymes and in the oxygen-carrying enzymes of higher animals. It seems as if Nature having discovered this particularly stable skeleton has found means of utilizing it in a number of different functions. This point of view is substantiated by the observation that the chlorophyll molecule is to-day manufactured by a sequence of reactions almost identical with the sequence of reactions used to manufacture the hæm. The branching between these two syntheses only occurs at the stage when the metal cation (ion or magnesium) is introduced into the porphyrin skeleton[16]. Following the opinion of Gaffron[17], a number of other dyes could have been utilized with just as much efficiency than porphyrins in the photosynthesis apparatus. Gaffron infers, therefore, that the porphyrins owe their predominant position essentially to the fact that they came first and were much more stable than other pigments. On the other hand, Calvin[15] has indicated strong reasons why, once the porphyrins formed, more of them will have a tendency to be formed by an autocatalytic self-selection mechanism due to the evolutionary pressure of peroxides.

The second example of polyfunction concerns the problem of adenine. This molecule seems to play an apparently unique part in Nature. It is one of its most important single compounds and it enters into the constitution of a great number of complex biomolecules. Thus, adenine, besides contributing to the structure of the nucleic acid, is also a part of several fundamental coenzymes (DPN, TPN, FAD, CoA) and other important transfer agents (*S*-adenosylmethionine), and it is also the carrier of the pyrophosphate chain in the energy-rich ATP and ADP. The clue to this omnipresence may perhaps reside in the fact that, as shown by calculations[18,19], adenine has the greatest resonance energy among all the biochemical purines. It may not be unreasonable to imagine that, inasmuch as Nature was induced to utilize a purine or pyrimidine base as a constituent of these fundamental biochemicals, a phenomenon of natural selection played a part, leading to the choice of the energetically most stable base. (This is, however, certainly not the only reason for the use of adenine, for example, in coenzymes. In these compounds adenine probably serves for the binding between the coenzyme and the apoenzyme. An essential role in this binding seems to be played by the NH_2 group of adenine[20]. This is a very reactive amino-group (more reactive than that of guanine or of cytosine)[18,19]. A highly-reactive group, fixed on a very resistant skeleton, obviously represents a most successful combination for reactions involving this group. The same reason may be operating in ATP.)

Until now we have considered the resonance stabilization of conjugated biomolecules as a thermodynamic advantage of their ground-state. In fact, this stabilization seems to be equally effective in a second field in which its role must have been particularly important for the biochemical evolution. This second field concerns the effect of ionizing and ultra-violet radiations. As demonstrated in details in the particular case of biochemical purines and pyrimidines, there is a very close parallelism between the resonance stabilization of biochemicals and their resistance to damage produced both by ionizing and ultra-violet radiations[21,22]. The intimate nature of this correlation is not entirely elucidated, but it seems highly probable that one of its predominant factors is the possibility for resonating molecules to produce, under the influence of the radiation, relatively long-lived stable excited states. This possibility must have been particularly advantageous for the evolution of life under the early conditions of the Earth in which the energy derived from the Sun in terms of radiation or electronic discharges was the primary source of energy for the synthesis of molecules and even for the polymerization processes leading to macromolecules. The conjugated systems, the loosely bound π and lone-pair electrons of which may be relatively easily raised to the excited states were among those which could make the most efficient use of the available light energy[23]. It is possible that the $n \rightarrow \pi^*$ transitions of resonating heterocycles have been particularly advantageous in this respect, as they also seem to be nowadays in bioluminescence[23]. (We shall see later other reasons which point to the importance of the lone-pair electrons and of their participation in electronic delocalization for the processes of life.) The involvement of resonating molecules, retinenes, as primary receivers of light in vision, is, of course, self-explanatory. Less self-evident, but no less significant, is the involvement of retinenes also in the sense of smell[24].

This same factor of stabilization through electronic delocalization might probably have played also a part in the evolutionary production of the huge macromolecular polymers, in particular nucleic acids and proteins. Such a formation is undoubtedly associated with complementary stabilization. As already mentioned, the hydrogen bonds of proteins connect the otherwise isolated π-electron possessing peptide links into a one quasi-conjugated π-electron system. A more quantitative observation concerns the complementary resonance stabilization through hydrogen bonding of the purine–pyrimidine pairs of the nucleic acids. Calculations have predicted that this stabilization should be, by about 1 kcal/mole, greater for the guanine–cytosine pair than for the adenine–thymine pair[25]. This prediction is remarkably confirmed by experiment[26] which indicates that the denaturation temperature of the nucleic acids rich in guanine–cytosine is appreciably higher than that of the nucleic acids rich in adenine–thymine. In fact, so far as our present knowledge goes, the purine–pyrimidine pairs which actually exist in DNA seem to be more stable than the artificial combinations recently created between other related polynucleotides[27]. In the nucleic acids there is probably moreover, besides the hydrogen binding between the complementary purine–pyrimidine bases, the possibility of electronic interactions among the π-electrons of the parallel stacked base-pairs, either by direct σ-type overlap of their electronic orbitals[28,29] or by a charge transfer complex formation between them[30,31] or by polarization binding. Moreover, such surprising selection phenomena as the exclusive use of D-sugars in the nucleic acids and L-amino-acids in the proteins correspond also to stability requirements, as it is only such a selection that permits the construction of regular helices with minimum strain[16].

Nevertheless, it seems certain that in fact this elaboration of biological macromolecules, which may be considered as the second important stage in the pre-biological evolution (the first one being the selection of the appropriate conjugated molecules) offered also appreciable functional advantages over the use of smaller compounds[32], and this situation brings us to the discussion of this second factor responsible for the evolutionary selection of conjugated molecules in biochemistry.

Functional Advantages

Life is a delicate, dynamic equilibrium between a series of synthesis and decomposition phenomena. Among its main characteristics are the constant mobility of its mechanisms, the interdependence of its constituent biochemicals, the long-range transmission of its manifestations and its numerous transducing activities. It appears obvious that the mobility, the fluidity, the great polarizability of the electronic cloud of conjugated molecules, the possibility that the existence of such a unique, large and deformable cloud offers for the rapid and distant transmission of perturbations (which in biological language may mean an order or a warning) represent important functional advantages which make the conjugated systems particularly suited to perform the functions required by the existence of the living matter. The essential fluidity of life agrees with the fluidity of the electronic structure of these compounds.

As mentioned before, a number of functional advantages may be found for the utilization of macromolecular polymers as the fundamental substances of life. Among those some are very explicitly related to the enhanced and extended electronic delocalization which occurs in such compounds.

Thus, although the exact nature of the semiconductivity observed in such polymers and in other organized, solid state like biological structures[6,33] is still uncertain (intrinsic electronic conductivity or extrinsic electronic conductivity or ionic conductivity) it nevertheless obviously represents a most interesting procedure for the long-range transmission of electronic perturbations. Inasmuch as catalysis by semiconductors involves the formation of charge transfer complexes between the catalyst and the substrate, the theoretically predicted decrease in ionization potential and increase in electron affinity of a protein chain with respect to these properties in an isolated peptide link may have an important significance for the catalytic activity of enzymatic proteins[3,9].

In the very important field of bioenergetics, the utilization of the 'energy-rich' phosphates as the principal coupling agents for the driving of anabolic reactions springs out from some advantageous characteristics of these compounds which, again, are due to the conjugation of their mobile electrons[34]. Thus, the principal sources of the 'energy-wealth' of these phosphates are: (1) the resonance stabilization of the products of the hydrolysis; (2) the electrostatic repulsions due to the particular electronic distribution in the phosphates (consisting generally of a main chain of at least three and frequently more atoms carrying net positive charges surrounded by a cloud of negatively charged atoms), distribution which is a direct result of the delocalization of the mobile electrons; (3) the keto-enol tautomerism of the products of the hydrolysis; (4) the free energies of ionization. The 'energy-wealth' is therefore directly dependent on the manifestations of electronic delocalization.

However, the most striking example of the functional advantages associated with the utilization of conjugated molecules in the living systems is offered by the case of coenzymes. Biochemical reactions need enzymes to proceed and enzymes are essentially proteins. However, the great majority of enzymes exert their activity in conjunction with a coenzyme in which case the essential reaction occurs at the coenzyme, the function of the protein (or apoenzyme) consisting mainly in ensuring the high efficiency and the specificity of the reaction, by suitably orienting and polarizing the reactants. Now, there are hundreds of enzymes but, as already mentioned, there is only a very limited number of coenzymes and practically all these coenzymes are conjugated organic molecules. This is in no way an accident but a deeply significant situation arising from the simple fact that these conjugated molecules are particularly well adapted for being the sites of biochemical transformations.

This may be illustrated by examples which we shall take in the field of two of the most important groups of coenzymes, the oxidation-reduction coenzymes and the group-transfer coenzymes.

Thus it has been shown[35] that the mechanism of functioning of the oxidation-reduction coenzymes (DPN, TPN, FMN, FAD, the hæm prosthetic groups of cytochromes) in electron transfer may be related to the values of the energies of the lowest empty molecular orbital (*lemo*) of their oxidized form and of the highest occupied molecular orbital (*homo*) of their reduced form and to the variation of the energies of these two essential orbitals in the course of the oxidation-reduction. It is observed that, in each case, the oxidized form of the coenzyme has a very low-lying *lemo* and the reduced form of the coenzyme a particularly high-lying *homo*. The oxidation-reduction of these compounds is thus associated with an instantaneous redistribution of these two essential orbitals in such a way that in each case the oxidized form of the coenzyme has a relatively great electron affinity or electron-accepting tendency and the reduced form of the coenzyme a particularly low ionization potential or a particularly strong electron-donating tendency. This oscillation makes these coenzymes particularly suitable for being the vectors of electron transfer. Now, obviously, only conjugated molecules can involve such a specific displacement of molecular orbitals and satisfy the conditions imposed on the efficient electron-transfer agents. In fact, even among the conjugated molecules themselves, only very specific ones can fulfil these requirements. Thus, for example, if we replace the nicotinamide ring of the pyridine nucleotides by benzene or the isoalloxazine ring of the flavin coenzymes by anthracene, nothing useful will happen. This remark brings us to an essential complement to our general thesis about the importance of conjugated molecules in the processes of life. Namely, that what is needed and essential are not simply conjugated molecules but, mostly, conjugated heterocycles disposing of atoms with lone-pairs, such as nitrogen or oxygen, which by undergoing suitable changes in their valence states are able to bring about the most economical and spectacular transformations. Thus the previously discussed redistribution of the molecular orbitals in the respiratory coenzymes, which apparently is so well adapted to the function of these coenzymes as electron transfer agents, is only possible because the oxidation-reduction is associated with changes in the valence states of the nitrogen atoms of these compounds, which alternatively involve their lone-pair in the overall π-delocalization or exclude it from such a participation. It may even be observed that owing to this modification in the valence state of the nitrogen atom the reduction of DPN+ to DPNH does not involve any loss in the total number of the π-electrons of the system (in DPN+, N_1 contributes one π-electron, while in DPNH it contributes its lone pair) and that the reduction of FMN to $FMNH_2$ involves even an increase in the total number of π-electrons (in FMN, N_1 and N_{10} contribute one π-electron each, in $FMNH_2$, they contribute two electrons each, namely, their lone pairs). Although the reduction is in each case accompanied by a certain loss of resonance energy[36], this loss is probably the minimum possible one.

Our second example comes from the field of group transfer coenzymes. We may specifically quote, as an illustration, the case of pyridoxal phosphate, although exactly the same or very similar considerations apply to other coenzymes of this category, such as thiamine pyrophosphate or tetrahydrofolic acid.

Pyridoxal phosphate, which is a heterocyclic aldehyde, catalyses a great number of group transfer reactions involving the α-amino-acids of the proteins[37]. The mechanism of functioning involves, in the first place, the formation of a Schiff's base (an imine) between pyridoxal phosphate and the α-amino-acid. This formation labilizes the departure of the COOH+, H+, and *R*+ groups attached to the α-carbon, permitting thus the involvement of the α-amino-acid in a series of reactions. It may be shown that the essential electronic factors connected with the catalytic properties of pyridoxal phosphate reside in[38,39]: (1) the strong resonance stabilization of the transitional form deriving from the initial Schiff's base through the labilization of any of the COOH+ or H+ or *R*+ groups, stabilization due to the increase in dimensions or the reorganization or both of the total conjugated system; (2) the creation in this transitional forms of prominent centres of extremely high reactivity (for example, great local concentrations of electronic charges or of free valences), which ensures the rapid consecutive development of the reaction towards its final products.

Thus the catalytic activity of this and similar coenzymes is essentially related to the transformation of the initial coenzyme–substrate complex into a resonance stabilized and, at the same time, electronically activated intermediate which is the essential active form of the reaction. Only conjugated molecules, with their cloud of mobile and deformable electrons and containing heteroatoms capable of oscillating between different valence states, can bring about such results.

These different phenomena definitely seem to point out that there were deep reasons for the evolutionary choice by Nature of conjugated molecules for biological purposes. We know, nowadays, owing to the work of a series of authors, that all the essential biomolecules, in particular the amino-acids[15,40,41] and even the fundamental purines[42,43] and pyrimidines[44], could have been produced and probably were produced in the early stages of the history of the Earth in a random, irregular, abiotic way. (An interesting point to investigate is to determine the probability factors or entropy contributions related to this formation. This unfortunately seems, at present, difficult for quantum chemistry.) It seems highly probable that the evolutionary selection tended then towards the biological utilization of the most stable compounds which, not by chance but by the particular virtue of the π-electrons, must have also been, at the same time, the most efficient and best adapted compounds for the biological purposes of Nature. We cannot say and do not want to say that life has originated with the appearance of the conjugated compounds but what may probably be safely said is that the possibility of life, in the form in which it is present to-day, has been rendered more probable and its development hastened through the utilization of such compounds. This fact is to some extent inherent in the very elementary chemical composition of the living matter[45]: 99 per cent of it is composed of hydrogen, carbon, nitrogen and oxygen, the last three first-row elements being among all the elements those which most easily form multiple bonds. The next two most abundant and important elements to enter into the structure of the cell are sulphur and phosphorus and these are practically the only ones other than first-row elements to form multiple bonds. One can also imagine[45] that carbon rather than silicon has been 'chosen' by Nature as an essential component of organic matter (although silicon is much more abundant on the surface of the Earth than carbon) possibly because carbon may form chains of conjugated double bonds while silicon cannot and possibly because carbon bonds are much stronger than silicon bonds. The choice and utilization of conjugated heterocycles as structural components of life appears thus as one of the most important quantum effects in biochemical evolution.

Resonance and Biological Evolution

We have considered so far the role of electronic delocalization or resonance in pre-biological, chemical evolution. It may be pointed out that the same factor might have had also a decisive influence on the biological evolution of species[46]. Thus, as is well known, the purine and pyrimidine bases of the nucleic acids are considered as existing essentially in the lactam and amino tautomeric forms. This situation is in agreement with quantum-mechanical calculations about the relative stabilities of the different possible tautomeric forms of the bases[3]. However, the involvement of rare tautomeric forms is considered as possibly playing an essential part in mutations[47]. The presence of a rare tautomeric form may produce an erroneous coupling, through hydrogen bonds, of unusual bases and may lead to an induced, self-perpetuary, perturbed sequence of purine–pyrimidine bases. As the genetic information is probably enclosed in this sequence, the result is a mutation. The situation concerns in the first place spontaneous mutations the occurrence of which appears as a physical necessity due to the mere existence of tautomeric equilibria and, secondly, to induced mutations, produced, for example, by base analogues or antimetabolites capable of increasing the frequency of the abnormal pairings.

Now, it can easily be shown[46] that one of the principal factors responsible for these tautomeric shifts towards rare forms and thus possibly responsible for the occurrence of mutations is a resonance effect. This is true in particular for spontaneous mutations Thus, the essential varying factor responsible for the relative tendency of the bases to exist in a rare tautomeric form is the variation of the resonance energy which accompanies the tautomeric transformations. There are two such transformations to be considered: the lactam–lactim and the amino–imine transformations. In the lactam–lactim tautomerism, the transformation of the lactam form (the most stable) to the lactim form (less stable) is accompanied by an increase of resonance energy so that the proportion of the lactim form will be the greater, the greater this increase. In the amino–imine tautomerism, the transformation of the amino form (the more stable) to the imino form (less stable) is accompanied by a decrease in resonance energy and will therefore be the greater, the smaller this decrease.

These considerations indicate clearly the predominant role of resonance energy variations in the production of spontaneous mutations and thus in the biological evolution. Explicit calculations carried out for the resonance energies of the different tautomeric forms of the purine and pyrimidine bases of the nucleic acids lead, moreover, to the prediction that the base which, from that point of view, should have the greatest tendency to exist in a rare form, either lactam or imino, is cytosine (a prediction which seems to be confirmed from the purely chemical point of view). So far as the starting hypothesis about the cause of spontaneous mutations is correct, it is the tautomerism of cytosine which may be expected to have the greatest probability of being involved in such mutations. Of course, from the practical point of view, it is evident that the electronic factor considered here cannot be the only one to play a part in this phenomenon. For example, the steric adaptability of the rare tautomer into the general architecture of the nucleic acid may play an important part in determining its aptitude to subsist and to be involved in coupling, through hydrogen bonds, with complementary bases. Löwdin[48] has pointed out recently the possibly important contribution of the mutual stabilization of two rare tautomeric forms engaged in such complementary binding.

If we add that the same phenomenon of tautomeric shift and erroneous coupling may possibly be one of the causes of 'ageing' (considered as a continuous loss of genetic information and an accumulation of sequence errors) and also of 'spontaneous' cancer, that induced mutations and perhaps also chemical carcinogenesis may be approached from a point of view very similar to that just described, that important drugs, whether harmful or therapeutic, are frequently conjugated or at least partially conjugated compounds, in fact, in the majority of cases, heterocyclics[49], we clearly realize to what a decisive degree is life depending on the properties of the mobile electronic systems of resonating molecules. In a recent paper on biochemical evolution, Rich[50] states that unfortunately, "at the present time, we do not have any guide lines for our thinking, that is general concept about molecular evolution which may prove of utility in understanding and interpreting the results". We hope that the reasons indicated here for the orientation of life towards the utilization of conjugated systems, in particular oxygen- and nitrogen-containing heterocyclics, may form such a concept.

This work was supported by grant *CY*–3073 from the U.S. Public Health Service (National Cancer Institute). The paper was prepared while we were visitors at the Quantum Chemistry Group at the University of Uppsala, Sweden. We thank Prof. Per-Olov Lowdin for stimulating discussions.

WHY AFTER-IMAGES ARE NOT SEEN IN NORMAL CIRCUMSTANCES

By NIGEL W. DAW

Research Laboratory, Polaroid Corporation, Cambridge, Mass.

AFTER-IMAGES are not seen in normal circumstances. If you look at the clock on the mantelpiece and then at the painting above it, you will not see any aspect of the clock superimposed on the painting. This fact is fundamental to the visual process.

Goethe considered this fact, and suggested that it was due to lack of attention on the part of the observer[1]. Helmholtz thought that it was due to the slow roaming of the eye, which occurs involuntarily, and which ensures that any such after-images will be out of focus[2]. A recent authority, in summarizing previous work, takes these two factors as the two main reasons for it[3]. However, the following experiments indicate that there is one important aspect which was touched on by Nechkovitch[4], but has otherwise received scant attention[5].

The experiments were designed to be related to vision in normal circumstances. Consequently they involved looking at a scene full of objects with highlights and shadows, and afterwards looking at a different scene (or a different part of the same scene) of approximately the same brightness. The first scene will be called here the primary scene, and the second scene the secondary scene. The experiments were confined in this way because it is quite rare in normal life that one looks from a scene of one brightness to a scene of another substantially different brightness. Generally one moves in an environment in which the average luminance in one direction is the same as that in another. When one does look at a part of a scene of one luminance followed by another part of the scene of a much lower luminance, one does see after-images. Looking at a light bulb or a photographic flash are examples. This type of situation will not be considered here.

The stimulus for these experiments came from the work of E. H. Land, who has demonstrated how a pair of transparencies, one projected in red light and the other in white light, can give the sensations of red, white, pink, grey, yellow, blue, green, brown, orange and black[6]. Some authors have suggested that these colours are partly due to successive contrast, which is equivalent to saying that they are due to after-images[7,8]. However, the colours are found to be independent of the part of the scene which the observer has been looking at previously, and, further, the colours seen in a flash of light are found to be much the same as those seen in continuous illumination[9]. The same question arises here as arises in the ordinary world, namely: is it really true that our perception is confused with after-images and successive contrast?

The primary scene in the first experiment was a coloured scene. It was made up from a red colour separation positive (Fig. 1) projected in Wratten No. 24 red light, superimposed on a green colour separation positive (Fig. 2) projected in tungsten light. The observer was asked to fixate on the end of the teapot spout for 12 sec. At the end of this time the red light was turned off, so that the secondary scene consisted of an ordinary black and white photograph.

The observer saw a coloured after-image if he continued to look at the end of the teapot spout. The colours of this after-image have been described by Land[10]. The pillow behind the teapot is a deep cyan (it was red in the primary scene); the decanter and the other pillow (which were cyan in the primary scene) appear a pale brown, or pink; the stapler appears grey, as it was in the primary scene. The colours are the same if other points of fixation are used, provided the same point of fixation is used for both the primary and secondary scenes. Some observers found it a little difficult at first to describe the colour of the decanter while fixating on the end of the teapot spout, but were able to do it after practice.

If the observer did not continue to look at the end of the teapot spout, the coloured after-image disappeared. The whole scene became black and white,

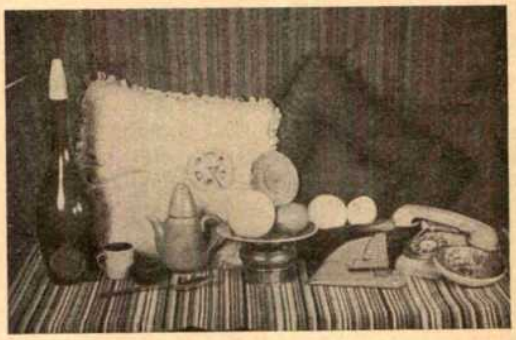

Fig. 1. Red colour separation positive for the first experiment

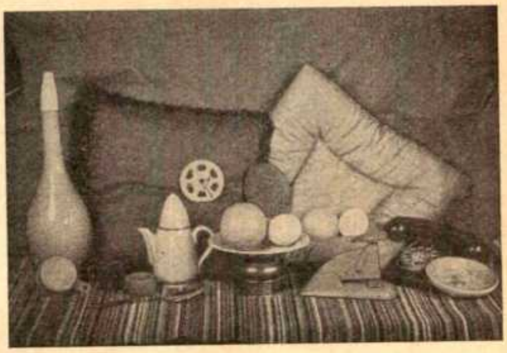

Fig. 2. Green colour separation positive for the first experiment

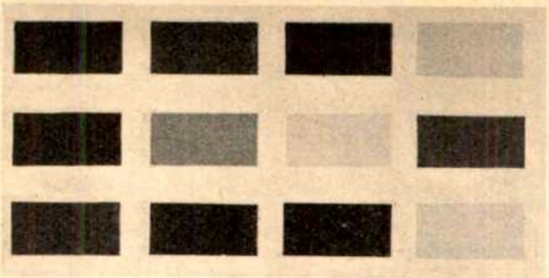

Fig. 3. Red colour separation positive for the second experiment

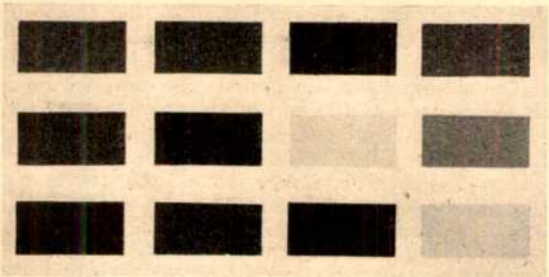

Fig. 4. Green colour separation positive for the second experiment

not cyan, as one might expect from the fact that the observer had previously been staring at a scene illuminated with wave-lengths predominantly from the long end of the visible spectrum.

If the observer looked away from the end of the teapot spout and back again, the after-image disappeared when he looked away and re-appeared when he looked back again, provided the time elapsed since the change from the primary scene to the secondary scene was not too great. He had to look back to exactly the same point for the after-image to re-appear. The end of the teapot spout was chosen as a point of fixation because it was clear, small, and well defined. An observer who fixated carefully on it during the primary scene found, while he was looking at the secondary scene, that a slight movement to either side of the point was enough to destroy the whole after-image.

The after-image took about 12 sec to disappear totally. During this time the observer could look away from the end of the teapot spout and have the after-image disappear, look back again and have it re-appear, and repeat this several times. Each time the after-image re-appeared it would be fainter, according to the time which had elapsed since its formation, but quite readily apparent.

The period of 12 sec fixation on the primary scene was carefully chosen. A longer period gave a stronger and more lasting after-image, but was inconvenient because it took the observer several minutes afterwards to recover fully, and necessitated a long delay before the next observation could be made. In addition, most observers found it hard to fixate for more than 12 sec. A shorter period gave a weaker and less-lasting after-image (as a rough guide we found that the after-image lasted about as long as the fixation time taken to form it). This was also inconvenient, because it did not give the observer time to look away from the end of the teapot spout and back again several times before the after-image had faded. Twelve sec fixation was found to be a good compromise.

Occasionally an observer would see an after-image when looking at some point of the secondary scene away from the end of the teapot spout. The after-image would appear in this case only after 1–2 sec of concentration on the new point of fixation, and may have been what Goethe was referring to when he said that an attentive observer will see after-images everywhere. The sensation was ephemeral compared with that obtained on looking back at the original point of fixation, when the after-image re-appeared immediately and unhesitatingly.

The primary scene for the second experiment consisted of a coloured geometrical figure. As in the first experiment, it was made up from a red colour separation positive (Fig. 3) projected in Wratten No. 24 red light, superimposed on a green colour separation positive (Fig. 4) projected in tungsten light. The observer was asked to fixate on a point *A* for 12 sec. Then Fig. 3 was occluded. Thus the primary scene was a coloured set of rectangles, and the secondary scene a black and white set of rectangles.

If the observer continued to fixate on point *A*, he saw a coloured after-image, as in the first experiment. He also saw a coloured after-image when he looked at the top right-hand corner of any of the other rectangles, where the geometry of the after-image fitted the geometry of the secondary scene. The colours were different, because the after-image was registered with a different set of rectangles of different lightnesses in the secondary scene, but they were

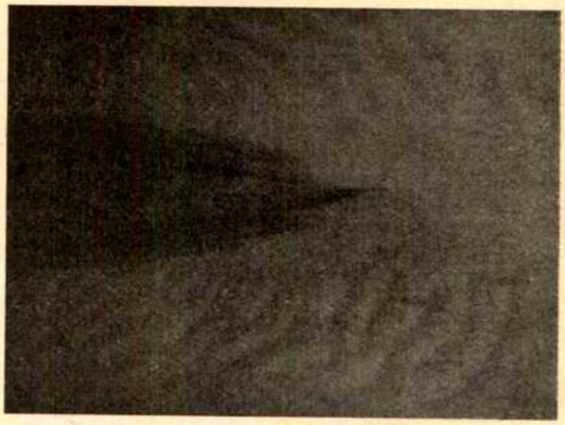

Fig. 5. Scene with soft contours

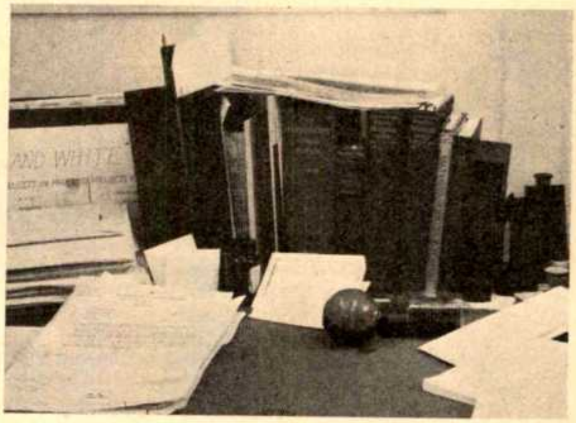

Fig. 6. Scene with hard contours

readily apparent. The observer saw them immediately, whenever his eye paused on the top right-hand corner of a rectangle.

In the third experiment the shapes of the objects in the primary scene differed from those in the secondary scene. The primary scene was Fig. 1 illuminated by light of 615 mμ (slightly different from the primary scene in the first experiment, which contained both Fig. 1 and Fig. 2). The secondary scene was one of a variety of transparencies (Figs. 2, 5 and 6 are examples) illuminated by white light. These were chosen to give a variety of types of scene, some with hard contours, some with soft contours, and one with no contours at all. The purpose was to find out if they would all inhibit the after-image to the same extent.

We found that the after-image was far more apparent with Fig. 2 as the secondary image than with any other. Using Fig. 6 very little after-image was apparent; using Fig. 5 the portion of the after-image due to the black/white contours in Fig. 1 was apparent; using a plain grey background some out-of-focus contours were apparent. In none of these cases, however, was the after-image as stable and colourful as it was with Fig. 2; the after-image would appear to a certain extent immediately the scene was changed, but a movement of the eyes would destroy it, and concentration for a second or two was required to bring it back again.

These three experiments were all observed by a number of people on various occasions at an average luminance of about 1 foot-lambert, which corresponds to a not very highly lighted room. Two observers looked at them, in addition, at average luminances of about 15, 100 and 500 foot-lamberts, which correspond to a moderately well-lighted room, a dull day outdoors, and a moderately bright day respectively. In the last two cases different pictures were used, but essentially the same series of experiments was performed. The results were the same, except that the after-images tended to fade more rapidly at the higher brightnesses.

The first conclusion from this is that the after-image is inhibited rather than destroyed. The first experiment showed that it will re-appear whenever the eye goes back to the original point of fixation. The second experiment showed that it will appear whenever the eye moves to a new point of the scene where the scene fits the after-image. As the eye moves around the scene the after-image stays with it, invisible and intact, in spite of all the other impressions made on the retina. It re-appears when the eye is rotated to a position in which the after-image is in geometric registry with the scene which originally produced it, provided the time elapsed since its formation is not too great.

The second conclusion is that when the contours of the after-image are inhibited, its colour is also inhibited. In the first experiment, when the observer looked away from the end of the teapot spout, and the after-image disappeared, there was no significant overall cast of cyan. The secondary scene appeared black and white.

The third conclusion is that one needs contours and detail in the secondary scene to do the inhibition with complete effectiveness. Some parts of the after-image may re-appear to a small extent when the secondary scene consists of weak and ill-defined contours. When it has no contours at all, that is, when it is a uniform white or grey, the after-image may appear fairly complete. One way of expressing this is to say that the after-image is always in registration with a uniform surface, whatever the point of fixation. However, even in this case, it is out of focus and ill-defined. Only when the contours of the secondary scene fit the after-image closely, does the after-image appear with its maximum stability and colour.

What is the significance of these conclusions for vision in normal circumstances ? One might argue that they are irrelevant, because one does not ordinarily fixate on anything for as long as 12 sec, so that after-images are never formed. However, it is possible to form an after-image in much less than 12 sec. We found, in the first experiment, looking at the end of the teapot spout, that less than 1 sec of fixation was sufficient to form a weak after-image. In ordinary life, one quite frequently looks at an object for 1 or 2 sec. We only chose 12 sec fixation in this experimental work, as explained here, to bring out the points clearly and concisely. Consequently, I believe that the conclusions from the experiments are applicable to normal vision.

Thus we have three explanations of why we do not see after-images in normal circumstances: Helmholtz's, Goethe's, and that described in this article. In my opinion, Helmholtz's explanation, and the explanation given in this article, are the true ones. Helmholtz says that one does not normally form an after-image because one does not normally look at any point of the scene long enough to do so: this paper shows that one will form an after-image after more than 1–2 sec fixation, which is quite common; but that it will be inhibited by any subsequent pattern of stimulation the contours of which conflict with it. Goethe's explanation is not so much an explanation as a prescription for the kind of procedure one should follow in order to see after-images. He says that the attentive observer will see after-images everywhere. So he will, if he does an unusual amount of fixation; but this would be abnormal behaviour.

In summary we may say that we are continually forming after-images, even at quite moderate levels of illumination. Some are quite strong, and some are extremely weak, depending on how long the eye rests on a point in the scene it is looking at, before moving on around the scene. The eye carries these after-images with it as it moves, and they will be seen whenever the eye alights on a point where the scene is in geometric registry with the after-image. However, this rarely happens in the ordinary world, where we are faced with trees and houses, with faces and dresses, and not with simple geometrical figures. The first experiment corresponds to the kind of scene we see in the ordinary world—full of objects of various shapes, with highlights and shadows on them. In these circumstances the after-image is completely inhibited.

MODELS FOR SUPERPOSED LAMINAR FLOW FOLDING

By E. S. O'DRISCOLL
Department of Mines, South Australia

IN recent papers[1-3] I described the experimental development of laminar models to demonstrate geological concepts of surface and internal shape transformations resulting from the mutual interference of superposed systems of defined similar folds. These models have been extended and adapted to show other aspects of laminar flow transformations in a general study of rheid[4] morphology related to specified strains.

The accompanying Figs. 1–4 depict an improved laminar model in which the relief of a bi-component (sinusoidal) interference surface is automatically delineated by true contour lines resulting from the combined effect of a regular succession of horizontal lines pre-printed on the card laminæ. With sufficiently thin laminæ the successive traces of these lines produce the effect of continuous contour planes emerging in correct position at the slopes of the interference surface.

Fig. 1 shows a specimen contour card lamina imprinted with horizontal contour lines, and with a specified profile curve, *BX*, representing the first fold system with its axial planes parallel to *BQ*.

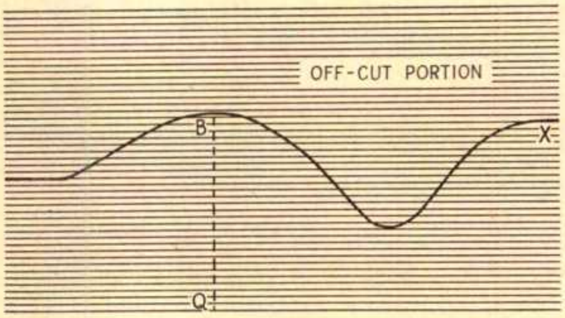

Fig. 1. Contour card lamina printed with horizontal contour lines. The profile *BX*, drawn on the outside card only, is cut through the pack by band-saw

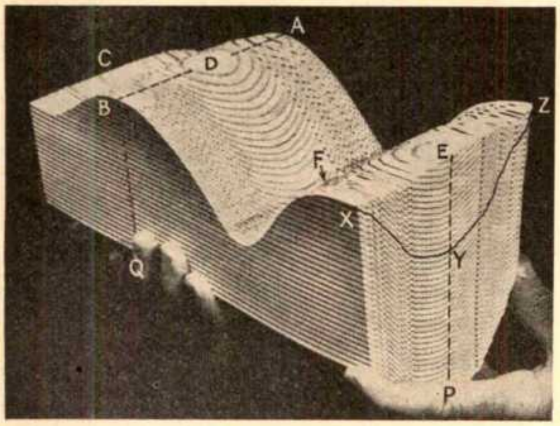

Fig. 2. Contour model showing two fold systems on upper and lower surfaces prior to their mutual interference

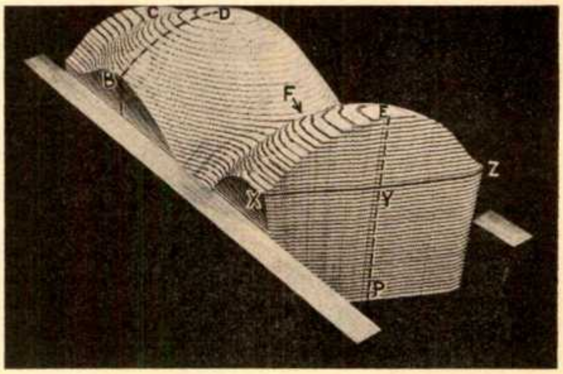

Fig. 3. Interference surface from superposed deformations shown in contoured relief

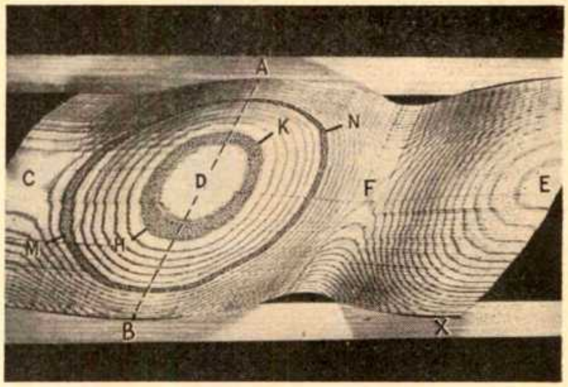

Fig. 4. Vertical view of interference surface showing elliptical contours in sigmoidal echelon. Component fold axes are *AB* and *CF*

In contrast to the operational sequence previously described[1], the profile curve *BX* is not cut until after the second specified fold system has been moulded in reverse into the bottom of the card pack.

Fig. 2 shows the model at the stage where a simple second-fold anticline has been moulded in reverse (that is, as a syncline) into the bottom surface of the pack causing the contour lines to form a succession of internal surfaces parallel to the bottom surface according to the profile *XYZ*, which represents the second-fold system having its axial planes parallel to the plane containing *P*, *E* and *D*. The profile *BX* has been cut to represent a first-fold system having its axial planes parallel to the plane containing *A*, *B* and *Q*. At this stage, both systems of folds exist in the model as two separate and independent deformations, one at the top and one at the bottom of the pack. Their mutual interference is effected by flattening the bottom of the card pack as in Fig. 3, where the model is shown supported in a wooden jig. This movement not only produces the interference relief on the top surface, but also restores the contour

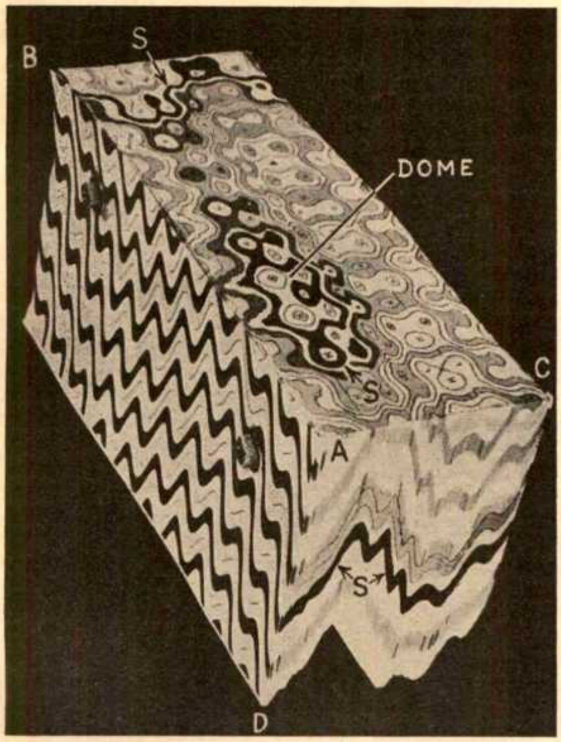

Fig. 5. Horizontally truncated model showing 'outcrop pattern of multi-wave interference complex

lines to positions where they produce the effect of correctly spaced horizontal contour planes within the pack parallel to XYZ (now a horizontal straight line). The specified curved profile formerly represented in reverse by XYX in Fig. 2 is now represented correctly in Fig. 3 as an anticlinal profile passing through X, E and Z. The points D and E represent the crests of interference domes circumscribed by true contour lines which automatically fall into position on the slopes.

Fig. 4 shows a vertical plan view of the resulting contoured interference surface. The non-orthogonal axial directions of the two interfering fold systems are respectively AB and CF, and the elongation of the resulting interference domes, D and E, are oriented into the acute angle between them. The connecting cols, or saddles, are seen at C and F. Two contour intervals at different levels of dome D have been stippled to emphasize the change of domal elongation direction from MN at the lower contour to HK at the higher. This is a right-hand sigmoidal elongation as will be seen by tracing the locus of corresponding points of maximum curvature on all successive contours.

Fig. 5 shows an elaborated version of a fold profile card model which demonstrates the plane 'outcrop' pattern of two orthogonal 'multi-wave' systems in mutual interference. The two component profiles can be seen respectively as the curve printed on the lamina BAD, and the moulded shape of the bottom of the card pack as seen on the end section CAD. One particular stratum, S, has been accentuated and its 'outcrop' pattern on the horizontal plane is shown on the top surface BAC. The combination of axial and quadrantal directions is evident, and the gross trend of stratum S in the vicinity of B is at right angles to its gross trend in the elongated dome near A.

I have also prepared simplified model presentations of laminar flow concepts to show the two-dimensional transformations of specified initial shapes by simple shear strain. This is achieved by inscribing such shapes on the surface formed by the edges of the laminæ. Subsequent simple shear movement of the laminæ causes this surface to deform as if by laminar flow, and the inscribed shapes are transformed accordingly.

Figs. 6*a*, *b* and *c* show a succession of such shape transformations under the influence of uniform homogeneous simple shear acting in a clockwise direction. The observed surface, which has been inscribed with shapes common to sedimentary rocks, is shown in Fig. 6*a* in its initial unsheared state. AB represents an irregular rippled stratum in which the top and bottom ripples are unequal and out of phase. CD represents a stratum containing elliptical elements, such as concretions or pebbles, with their long axes along the bedding. The thickness of the stratum CD is arbitrarily defined as 10 units. EF represents a stratum with regular approximately symmetrical ripples. MN represents the approximate bedding direction and PM an approximately orthogonal element in a bed, such as a vertical worm burrow or a perpendicular fracture. S represents a reference circle in the unsheared position which becomes the conventional strain ellipse after shearing.

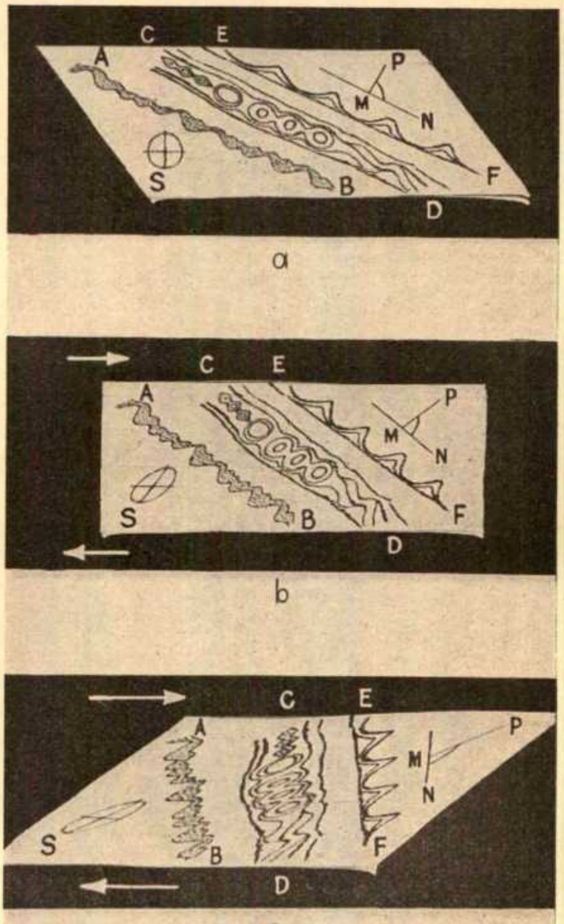

Fig. 6. *a*, *b* and *c*, Formal elongations and symmetry reversals produced by uniform continuous shear

Fig. 6*b* shows the same laminar model after the application of clockwise shear (indicated by arrows). The resulting strain, seen in the strain ellipse *S*, has produced some remarkable transformations in the inscribed elements. The ripples in strata *AB* and *EF* have become accentuated in amplitude and asymmetrical in a dextral sense, such as might lead to the wrong supposition of original depositional or slump flow from *A* to *B* and from *E* to *F*. Stratum *CD* has increased its thickness from 10 to 15 units, and the enclosed elliptical elements have been re-oriented at large angles to the bedding plane where they lie imbricated dextrally or in right-hand echelon with respect to the stratum. Their elongations are not coincident with the strain ellipse elongation. Cross-bedding near *D* has become decidedly condensed. The angle *PMN* is now conspicuously less than 90°.

Fig. 6*c* shows remarkable accentuations and formal reversals following the continued application of the same initial clockwise shear. The increased strain elongation is shown in *S*. The ripples in strata *AB* and *EF* are now greatly accentuated in amplitude and resemble intraformational slumping and flame casts respectively. Their asymmetry has reversed to a sinistral sense such as might suggest flow from *B* to *A* and from *F* to *E*, contradicting the earlier supposition based on the previous figure. The stratum *CD* has increased its thickness to 25 units, and the original slight irregularities in its top and bottom boundaries have become much exaggerated. The intraformational elliptical elements, while remaining oriented at large angles to the bedding plane, are now imbricated in a sinistral sense, or in left-hand echelon with respect to the stratum, an attitude conventionally associated with anticlockwise rotation, but shown here to be produced, paradoxically, by clockwise rotation. The original cross-bedding at *D*, now scarcely recognizable as such, might lead to the supposition of aberrant tectonic discordance. The angle *PMN* has become greater than 90°, showing marked attenuation in the line *PM* and corresponding condensation in the line *MN*. Between the stages of deformation in Fig. 6*b* and Fig. 6*c*, there was a point of transition where the angle *PMN* became 90° for the second time, restoring, at that point, the initial orthogonal relationship. Coincidently, the ripples in *EF* became symmetrical for the second time, but with exaggerated amplitude. Observations based on shape criteria at the transition point would have wrongly suggested tangential compression without shear rotation. It follows that if the intensity of the clockwise shear movement varies, the analogues of Figs. 6*b* and 6*c* may co-exist and falsely indicate independent opposing tectonic influences.

Additional models similar to Fig. 6 have shown that very slight initial sedimentary disharmonies can become so exaggerated and rotated by continuous simple shear as to produce entirely misleading evidence of origin based on assumptions of shape. A laminar model representing a simple curvilinear granite surface of unconformity overlapped by sedimentary 'pinchouts' can, when sheared, simulate an intrusive contact in which the beds of the overlapping sediments appear to be orthogonally truncated by the granite surface, or even engulfed in re-entrant angles of the granite. This produces the effect of a large-scale gross concordance prevailing over a succession of small-scale discordances. In this context also, any contrasting linear element, such as a quartzitic seam, provided it has the slightest initial undulate form, can be transformed to classical ptygmatic folds by the one uniform homogeneous shear. If inclined shearing of periodic intensity be applied to independently undulate surfaces, opposing overturns can be produced which simulate conventional compressional criteria in spite of the fact that the deformed surfaces have been attenuated.

Analogues of Fig. 4 may be seen in most cross-folded sedimentary sequences. Surficial expressions of Fig. 5 may be seen abundantly in the Proterozoic rocks of South Australia. Shear transformations of the type shown in Fig. 6 are observable both in the Precambrian rocks of Broken Hill, New South Wales, and particularly in the lower Paleozoic (Kanmantoo) rocks of South Australia.

PARALYSIS CAUSED BY THE DIGGER WASP *PHILANTHUS*

By Dr. W. RATHMAYER
Zoologisches Institut, Universität München

WITH one or more stings, the females of almost all Sphecidae can paralyse other insects or spiders, which they then carry into brood cells as food for the larvæ (Fig. 1). The problem of stinging had been considered by earlier investigators, but the controversy whether the sting reaches the central nervous system of the prey or whether injection of the poison into the hæmolymph is sufficient for the paralysis has not been settled. Two histological investigations of the nervous system of paralysed insects produced quite different results[1,2].

In the case of the digger wasp, *Philanthus triangulum*, F., this issue for the most part has now been resolved. Moreover, indication of the specific action of the poison involved has also been obtained[3].

To discover whether or not the central nervous system is reached it is necessary to locate the actual place of puncture. When *Philanthus* was allowed to sting honey-bees in small containers, the sting was always observed on the unsclerotized membrane on the ventral side of the bee behind the first pair of legs (Fig. 2). Following the stinging, which lasts about 30 sec, the wasp turns its victim venter up tightly beneath the body. With the rectangular shaped tip of its abdomen the wasp squeezes the abdomen of the bee telescopically. As a result of the pressure the honey-stomach bursts, the contents of which are immediately licked up by the wasp (Fig. 3). Nearly always the wasp drums the spot where it has stung with the proboscis and frequently kneads the bee's legs with its mandibles. This action, performed by a few other digger wasps, is known as 'malaxation'.

Also under natural conditions, the sting is given behind the right or left coxa of the fore legs. Histological sections through this area showed in ten out of

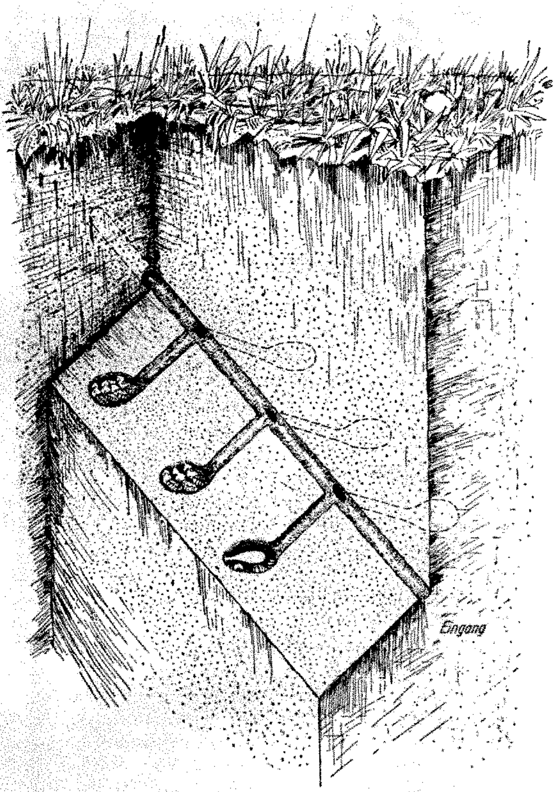

Fig. 1. Nesting place of the digger wasp *Philanthus triangulum* F. Paralysed bees are stored in the brood cells. In the first chamber a larva has already spun its cocoon

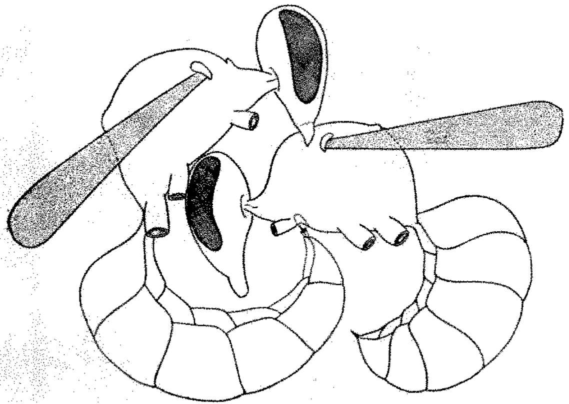

Fig. 2. The sting of *Philanthus* is always placed behind the first pair of legs on the ventral side of the bee

twelve cases studied that the sting had not reached the first thoracic ganglion. In the other two cases, the perilemma of the ganglion in the region of the endosternum I was damaged. Presumably the wasp's sting had broken off and in this way reached the ganglion.

For *Philanthus* to locate this very small area for stinging without optical means requires specialized receptors on the sting apparatus. The sheath lobes of the sting are not attached to the oblong plates as two unsclerotized processes—as in the Apidae—rather they are chitinous and serve to guide the shaft of the sting itself. The distal ends of the lobes are enlarged and club-shaped and bear a pad of some seventy *sensilla chaetica*. These sensitive hairs range from 3 to 4μ in diameter and from about 45 to 90μ in length, and articulate proximally in the chitin. Fig. 4 shows the sting apparatus with the gland system as a whole. Furthermore, two additional types of *sensilla campaniformia* are found in the dorsal wall of the bulb of the sheath (Fig. 5, *S.c.A.* and *S.c.B.*). They are probably sensitive to tension stimuli in the chitin. This sense organ at the tip of the sting represents a highly specialized tango-receptor for soft unsclerotized spots and has been found with certain modifications in all species of digger wasps examined.

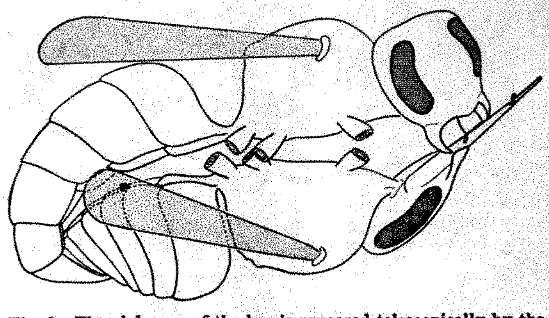

Fig. 3. The abdomen of the bee is squeezed telescopically by the wasp; in this way the contents of the honey-stomach are burst off

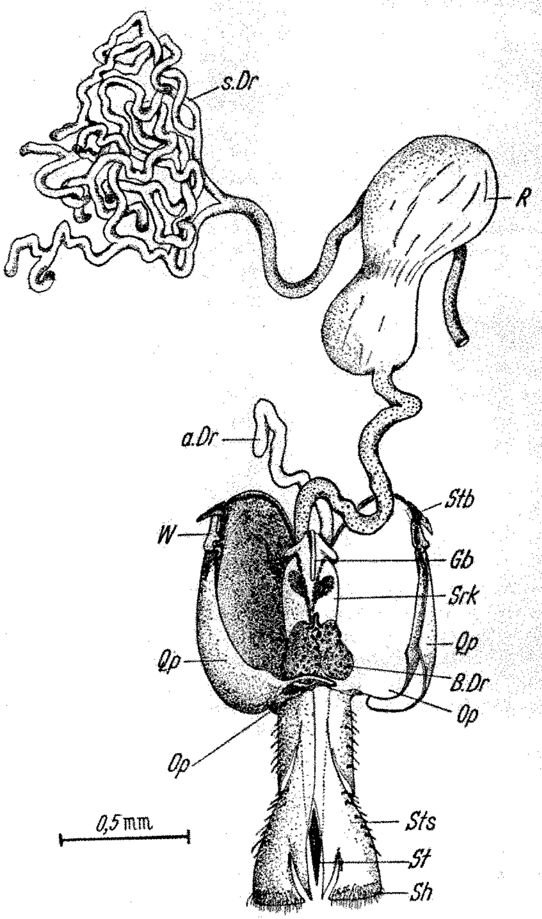

Fig. 4. Sting-apparatus of *Philanthus triangulum* with the various glands. Parts of the oblong and quadrate plates of sting are cut on the right side to show their anatomy. *aDr*, alkaline gland; *B.Dr*, Bordas gland; *Gb*, furcula; *Op*, oblong plate of sting; *Qp*, quadrate plate of sting; *R*, poison sac; *s.Dr*, acid gland; *Sh*, sense organ at the tip of the sheath lobes of sting (*Sts*); *Srk*, bulb of stylet; *St*, sting; *Stb*, lancet of sting; *W*, triangular plate of sting

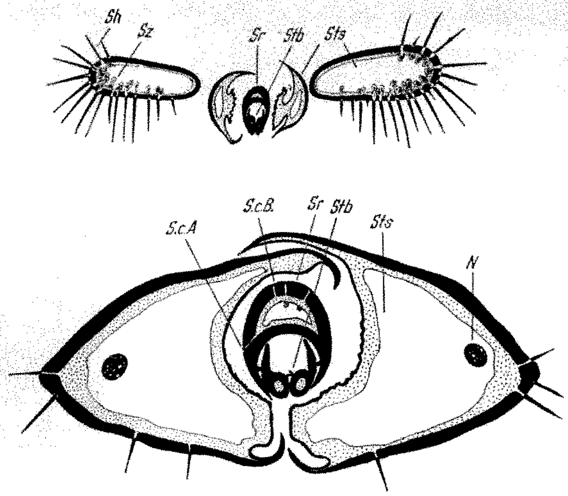

Fig. 5. Sections through the distal and middle part of the sheath lobes of sting. *S.c.A.* and *S.c.B*, two types of sensilla campaniformia; *N*, nerve from the sense organ *Sh* of Fig. 4 to the last abdominal ganglion. For other abbreviations see Fig. 4

The next important point to be considered is whether *Philanthus* chooses this particular spot behind the fore legs because it is one of the few places which can be pierced by the sting, or, whether it is necessary for paralysis that the stinging be near the thoracic ganglia. For a suitable explanation bees were stung experimentally by wasps at various distances from the ganglia. The spots were predetermined by cutting windows in the chitin with a very fine scalpel. After a normal stinging, the front and middle legs are immediately paralysed, the hind legs, after 1 min and the prætarsus after 30–40 min. Following an experimental stinging in the mesonotum, the bees are able to move forward for some 30 sec and only after this interval become paralysed. After 50–90 sec, the bee can no longer move about. When examined, it is seen that coxæ and femora of all legs are paralysed, but the tibiæ and basitarsi still kick vigorously. After some 15 min the basitarsi show evidence of paralysis.

When stinging occurs in front of the right tegula, the legs of the right side become paralysed faster and more thoroughly than those of the left side, and vice versa. Thus, there is a correlation between the side stung and the paralytic effect. Even stinging in the abdomen of bees will, after a certain time, produce complete paralysis. But in this case the onset of paralysis has been delayed by a few minutes. In the case of abdominal stinging, some bees recover after initial paralysis, that is, paralysis can be reversible. Relationship between place of stinging and the speed of paralysis can be shown. Following a stinging in the mesonotum, paralysis will appear after 65 sec; in the episternum, after 32 sec. On the other hand, if the bees are stung in the abdomen, paralysing effects occur after 220 sec.

Thus, for positive results the poison need not be injected near a thoracic ganglion, but may produce paralysis when it reaches the hæmolymph. Moreover, it does not produce a sudden paralysis but takes effect gradually. The theory that the poison is a neurotoxin which affects the central nervous system[1] cannot be experimentally sustained. The nerve cells for the different muscles of one leg are located very close to one another in the same thoracic ganglion and must be reached by the poison at practically the same time. Yet observations prove that the coxæ and femur are paralysed while the tibia and basitarsus of the same leg are still movable. If the poison causes accelerated degeneration of the central nervous system to the extent that Nielsen indicates, it is even inexplicable how individual bees can recover from paralysis. Obviously, another mechanism of poisoning is involved.

There are two methods for investigating where the poison of *Philanthus* primarily takes effect. Besides a histological examination of the central nervous system of paralysed bees, experiments involving smaller dosages of poison are most informative. Theoretically, if the poison does not affect the ganglia, assumed from previous experiments, then application of small amounts of the poison may cause a local paralysis to the actual effectors.

Newly hatched *Philanthus* possess very little poison. Experiments with such wasps showed that a sting near the tegula of a bee immediately paralyses the wings. Otherwise, the bee can move about quite normally. Only after a few minutes do the coxæ and femora become paralysed; the tibiæ, not at all. After 1 h at the most, the bees are again able to fly.

Consequently, the poison cannot be a neurotoxin which blocks the ganglion centres. If it were, the fore-wing and the middle legs, both of which are innervated by the second thoracic ganglion, would be paralysed at practically the same time and not after a maximal interval of 7 min. The poison has a peripheral effect, spreading first around the puncture and only by means of the hæmolymph reaching the leg musculature. The amount now present is insufficient for paralysis of the tibiæ. The progressive paralysis of the leg segments can be explained in the following manner. Those muscles which control movements of the coxæ and femora lie within the body proper and are bathed by the hæmolymph, which is responsible for a quick transport of the poison. The muscles of the tibiæ are located within the leg, namely, in the femora, and those of the basitarsi, in the tibiæ. It takes a considerable amount of time for sufficient poison to reach these muscles through the action of the accessory pulsating organs on the basis of the leg. The fact that the tarsus retains its mobility the longest of all supports this assumption.

Injection of small amounts of poison into the head of a bee will paralyse the antennæ and the proboscis, while the bee otherwise is unaffected. If the poison primarily affects the central nervous system, then the co-ordination necessary for movement would be disturbed. This is explained by the fact that the overlying centres for movement are located in the brain and subœsophageal ganglion. Whether the onset of peripheral paralysis is located in the muscle or in the axon or in the synapsis (most probably the latter case) is not as yet determined. Further investigations are planned.

Observations of the life-span of a paralysed bee show that 37 h after stinging heart activity can be demonstrated. But the frequency of heart contractions is disturbed, often bursts of a constant beat occur. Maybe this phenomenon is a result of a disturbance or blocking in the neurogenic pacemaker while the myogenic automatism, controlling the bursts, is unaffected[4].

To support the conclusion that the poison of *Philanthus* does not primarily affect the central nervous system, but first attacks the periphery, ganglia of paralysed bees were examined histologically. When sections were prepared 2–5 h after stinging, the brain and subœsophageal ganglion, likewise the second and third thoracic ganglion, showed no change. Only in the first thoracic ganglion, which lies in the immediate vicinity of the puncture, did glia cells and the neuropilem manifest alterations. Although the nuclei of the glia cells were present and the cell boundaries discernible. The plasma region of these cells appeared empty and the neuropilem did not evince its usual fibrous ground structure. The ganglion cells, however, remained unchanged. Only 24 h after stinging do the changes of the neuropilem and the glia cells spread to the other thoracic ganglions, but nerve cells and the cells of the perineurium are almost never affected. Not until three days after the stinging is shrinkage in the brain and the subœsophageal ganglion noticeable.

It is possible that after peripheral paralysis has set in, the poison disturbs the metabolic functions of the glia cells which are responsible for the nutrition of the neurones. The lack of essential nutrients could be the cause for the viscous degeneration of the neuropilem. The histological examinations have shown that the poison does not attack primarily ganglion centres, for those ganglions at some distance from the puncture, for example, the second and third thoracic ganglion, exhibit degeneration only after a day. The respective extremities, however, are immovable within a few seconds.

The potent effect of *Philanthus* poison is not confined only to the honey-bee. On the contrary, positive results were obtained with all insect orders, spiders and even closely related Sphecidae. Just as remarkable is the fact that *Philanthus* is immune to its own poison, toxicity being destroyed by a particular compound in its hæmolymph. Only in very strong concentrations can the poison cause a momentary paralysis in the musculature. Within a very short time the local paralysis is checked by the hæmolymph. If the poison is injected directly into a thoracic ganglion of a *Philanthus*, the legs will become paralysed. Whether in this instance the structure of the ganglion is damaged or a nerve–nerve synapsis is blocked has not as yet been determined. Since insect ganglia are not bathed by hæmolymph, the poison in this case cannot be rendered ineffectual.

Philanthus can be killed by its victim's poison if the bee successfully introduces its sting into the heavily sclerotized body of the wasp. This is, of course, an exceptional case. There is a Mediterranean species of digger wasp, *Palarus variegatus*, F, which preys among other aculeate hymenoptera on *Philanthus*. The apparent immunity of this species to the poison of the latter has obvious selective advantage. Whereas the victim's poison may be fatal to *Philanthus*, in this case, the hunter is immune to the poison of its prey.

OBITUARIES

Sir Irvine Masson, M.B.E., F.R.S.

Sir Irvine Masson, M.B.E., formerly vice-chancellor of the University of Sheffield, died in Edinburgh on October 22, 1962, at the age of seventy-five. He was a grandson of David Masson, professor of English literature at University College, London, from 1853 until 1865, and at the University of Edinburgh from 1865 until 1895, and the only son of Sir David Orme Masson, professor of chemistry at the University of Melbourne during 1886–1923.

James Irvine Orme Masson was born on September 3, 1887, in Melbourne, where he was educated at the Grammar School and the University before coming to Great Britain in 1910 as an 1851 Exhibition Scholar. After a year with Sir James Walker at Edinburgh, Masson moved to University College, London, where he worked with Sir William Ramsay, with whom his father had been associated some thirty years earlier at University College, Bristol. In 1912 Masson became assistant in chemistry at University College, London, and during the First World War he served first with the R.N.V.R. and later at the Research Department of the Royal Arsenal, Woolwich. He was appointed reader in inorganic chemistry at University College in 1920, and served as secretary of the Chemical Society during 1921–24. He became the first professor of chemistry and head of the Department of Pure Science of the University of Durham (Durham Division) in 1924, and in 1938 he went as vice-chancellor of Sheffield, where he remained until retirement in 1952. At the outbreak of the Second World War he added to his duties as vice-chancellor the active direction of a Ministry of Supply team which was housed in the Chemistry Department and engaged in research on explosives. He was also a member and chairman of several committees of the Ministry.

Irvine Masson was a man of varied talents. His chemical work, which led to election to the Royal Society in 1939, was not voluminous, since he never had a large team of helpers and much was done with his own hands. But his work is characterized by elegance and breadth; problems were reduced to the simplest possible terms and then approached by neat, ingenious and well-considered methods. He belonged to the group of chemists—now non-existent—who could tackle equally well problems in the inorganic, physical and organic sections of chemistry. His early publications were concerned with the theory of solution and the gas laws, and his use of the inert gases was clearly an outcome of association with Ramsay, for whom he had unbounded admiration. But his most significant contributions were his studies of nitration and of the organic compounds of iodine. The nitration work is a classic, paving the way for later researches which have had an important bearing on the development of theoretical organic chemistry. The study of organic iodine compounds had been neglected since the work of Victor Meyer and Willgerodt some forty years earlier; Masson developed this work in an important series of researches, in which he demonstrated once more his remarkable ability to apply physical chemistry to problems in both organic and inorganic fields.

Masson was interested in the teaching of science, frequently serving as external examiner at other universities, and his book, *Three Centuries of Chemistry*, published in 1925, shows a profound knowledge of the historical and philosophical aspects of his subject. While science was his profession, classics and the arts were hobbies in which he reached professional standing. He was a great lover of books and an expert in the early history of printing. His major contribution in this field—the fruit of research during the latter years of his vice-chancellorship—is an outstanding monograph on the *Mainz Psalters* and *Canon Missae*.

Masson was tireless in his efforts on behalf of the University of Sheffield, and his flair for the lucid presentation of complex matters of finance and statistics proved invaluable. No one knew better than he what education was or what a university should and could do. As vice-chancellor he steered the University through its war-time problems and through the equally difficult period of development which followed. He made plans to guide the expansion from 850 students to a well-balanced and effective University of some 2,500 students (a target now increased to 4,750); temporary structural alterations were made and building programmes initiated; Stephenson Hall and the new Chemistry and Engineering Departments were almost completed before his retirement in 1952.

Though invariably courteous and dignified, Masson was nevertheless a determined fighter, often outspoken in formal debate. In contrast, his natural shyness in personal relationships was a handicap frequently mistaken for aloofness. Rarely at his best in large gatherings, he was an excellent host of a small party, with a turn of wit which would have surprised his detractors. Those who knew him well found him a lively companion and a true friend.

Masson became M.B.E. in 1918, was knighted in 1950, and received the honorary degree of LL.D. of the Universities of Edinburgh and Sheffield. His retirement, spent in bibliographical work in Edinburgh and in advisory posts to the Carnegie Trust and the University of St. Andrews, was saddened by the long illness of his wife Flora Lovell, daughter of Prof. G. Lovell Gulland, whom he married in 1913 and who died in 1960. He leaves one son, who is sub-librarian in charge of the Brotherton Collection at the University of Leeds.

R. D. HAWORTH
A. H. LAMBERTON

Prof. Kh. M. Abdullaev

THE death of Khabib Mukhamedovich Abdullaev, president of the Academy of Sciences of Uzbekistan and former vice-premier of the Uzbek Council of Ministers, has been reported from Tashkent. Prof. Abdullaev visited Britain in 1960 and lectured on the geology and mineral resources of the Central Asian republics at several British universities. Although only fifty years old, he was the author of many geological monographs on the ore deposits of Central Asia, among them his doctoral dissertation on the scheelite deposits in the mountains of Uzbekistan and a number of lengthy works on the genetic connexion between mineralization and igneous intrusions. His book on *Dykes and Mineralization* (1957) brought him a Lenin prize; an English translation has just been published by the American Geological Institute.

Apart from his activities as an economic geologist, Abdullaev took a prominent part in the post-war organization of scientific affairs in Central Asia, in recognition of which he was awarded many Russian decorations. He spoke only Uzbek and Russian; but as a representative (and corresponding member) of the U.S.S.R. Academy of Sciences he latterly travelled widely on scientific missions to Western Europe, Mexico, China and India. He was a member of the Mineralogical Society of Great Britain.

NEWS and VIEWS

Biochemistry at Adelaide

SIR MARK MITCHELL, who has held the appointment of deputy vice-chancellor in the University of Adelaide since 1948, has resigned his chair of biochemistry in order to devote the whole of his time to the office of deputy vice-chancellor. Prof. R. K. Morton, Waite professor of agricultural chemistry in the University of Adelaide, has been appointed professor of biochemistry. Prof. Morton is a Fellow of the Australian Academy of Science. He recently returned to Adelaide after spending several months in England as a visiting Fellow under the auspices of the Commonwealth Fellowship and Scholarship Plan. Morton is distinguished for his work on purified enzymes and cytochromes including the first example of a protein containing two coloured prosthetic groups both necessary for enzyme activity. His method of purifying enzymes was a valuable contribution. He has also done important work on nucleic acids and plant proteins. During the Second World War he served in the Royal Navy and from 1949 until 1952 worked at Cambridge in the laboratories of Dr. Malcolm Dixon.

Demand for Graduates in Agriculture in Britain

IN a written answer in the House of Commons on November 27, the Minister of Agriculture, Fisheries and Food, Mr. C. Soames, announced that, with the Home Secretary and the Secretary of State for Scotland, he had decided to set up a committee of inquiry to assess the present and future demand, at home and abroad, by agriculture (including horticulture), its associated industries and public services, for graduates from agriculture and other faculties or departments of universities in the United Kingdom. The chairman of this committee would be Dr. C. I. C. Bosanquet and its members would be: Sir Arthur Benson, Mr. A. S. Cray, Mr. J. L. Davies, Mr. R. A. Hamilton, Prof. D. S. Hendrie, Dr. W. G. Humphrey, Prof. H. G. Lamont and Mr. Maitland Mackie.

The International Association for the Exchange of Students for Technical Experience: Annual Report

THE fifteenth annual report of the International Association for the Exchange of Students for Technical Experience covering the year 1962 has recently been issued (Pp. 88. Bad Godesberg: Dr. Klaus Wyneken, General Secretary, IAESTE, Frankengraben 50, 1962). The report records an increase of 185 over 1961 in students exchanged, 60 of whom were sent abroad by the new member country, Ireland, the remaining increase over 1961 being mainly from five countries. The main part of the exchange is still concentrated in the European area, where Germany, Sweden and the United Kingdom account for more than 50 per cent of the total exchange. Exchanges in the fields of architecture, chemical, civil and electrical engineering increased considerably and some 50 per cent of the 31 members (21 in Europe, 3 in Africa, 3 in America and 4 in Asia) have already arranged long-term training exchanges, part of which is with non-European countries. The present non-European countries increased their number of students sent from 585 to 681, and of foreign students received from 337 to 426. There was some exchange with non-member countries, and during its fifteen years' activity the Association has been able to arrange training periods abroad for 67,432 students. Of the 7,663 students sent in 1962, Germany (1,222), the United Kingdom (839), Austria (776), Netherlands (577) and Turkey (535) sent the most, and Germany (1,092), United Kingdom (749), Austria (746), Netherlands (538) and Sweden (471) received most. The United Arab Republic sent 345 and received 342 students. Of countries with an excess of students accepted over students sent, Germany (830) and Sweden (496) had much the largest, and of those with an excess of students sent over students accepted, Austria (416), Turkey (307), the United Arab Republic (230) and Yugoslavia (114) had the largest. Reports from the participating countries are included.

United Kingdom

A SEPARATE report for the United Kingdom (Pp. 13. London: International Association for the Exchange of Students for Technical Experience, United Kingdom, 178 Queen's Gate, S.W.7, 1962) includes notes on the first annual general meeting of the United Kingdom Association and on the fifteenth annual conference of the main Association at the Imperial College of Science and Technology during January 7–11, 1962. In 1962, 52 universities and colleges were affiliated in the United Kingdom Association, compared with 48 in 1961, and sent 839 students to 24 countries, receiving 848, compared with 894 and 965, respectively, in 1961. The Imperial College of Science and Technology (169), the University of Nottingham (55), the University of Cambridge (38), the University of Durham (37), the University of Manchester (35) and the Universities of Birmingham and Bristol (33 each) supplied the most students.

Overseas Students in the United Kingdom

MORE than 60,000 students from 140 countries were studying in Britain in 1961–62 according to *Overseas Students in Britain: a Handbook for all who are interested in the welfare of Overseas Students.* (Revised edition. Pp. 39. London: Standing Committee of the London Conference on Overseas Students, c/o the British Council, 1962. 1*s*. 6*d*. net.) More than 70 organizations concerned with overseas students are represented on the London Conference on Overseas Students, a permanent body with a secretariat provided by the British Council. The chairman, Sir John Macpherson, points out that the Conference is concerned with overseas students in Greater London, where some 34,400 are living and studying, and that there are similar co-ordinating conferences or committees in Birmingham, Bristol, Edinburgh, Glasgow, Liverpool and Manchester. The booklet contains tables of estimates of the numbers of full-time overseas students from each country, their subjects and places of study. Reference is made to the accommodation and personal problems of overseas students, and the booklet describes what is being done to help overseas students by the British Council and other British organizations, their own Governments, universities, technical colleges and other places of study. Attention is directed to the acute shortage of good accommodation available to overseas students and to the scheme which provides for Government grants for hostel projects.

The British Association for the Advancement of Science

THE annual report for 1961–62 of the British Association includes a report of the Council to the General Committee, the General Treasurer's statement and account, references to the publication of papers presented at the Norwich meeting and the report of the Seismological Committee on seismological investigations in 1961 (Pp. 100. London: British Association for the Advancement of Science, 1962. 2*s*. 6*d*.). The latter includes a note by J. H. Wavish on determination by electronic computer and one by Dr. A. E. M. Geddes on microseismic storms recorded at Aberdeen during the winter 1960–61. The Council's report notes the establishment of a new Area Committee at Southampton and the recognition of the Education Sub-Committee of the Manchester Federation of Scientific Societies as an Area Committee for the Manchester district and north Lancashire. More than 1,100 lectures were arranged by the Area Committees during the year to audiences totalling about 55,000 and the Junior British Association meetings have continued to show their value. Further science fairs were held at Middlesbrough in January 1962 and at Leeds in March 1962, and it is believed that the time is ripe for a major effort in Youth Clubs when the Government assistance for which the Association has already applied is forthcoming. The Mathematical Research Unit for the study of the generating of mathematical insights continued its work and the demand for visual aids again increased, but the major stress in the report is on the growth of the work connected with schools and young people.

Scientific Methods and Industrial Operations

THE work of the Industrial Operations Unit of the Department of Scientific and Industrial Research is concisely but effectively described with examples from the Unit's case-book studies and cartoons by Peter Kneebone in a booklet, *Science in Your Methods*, recently issued by the Department (Pp. 12. London: Department of Scientific and Industrial Research, 1962. Gratis). The booklet shows how scientific methods have already improved techniques and organizations in a varied range of industry and indicates some of the opportunities which industrial surveys afford. The Unit, which was established in 1952, does not normally undertake investigations for individual firms. Its three major functions are to demonstrate techniques that simplify industrial operations; to conduct instructional courses; and to examine the cost aspects of novel techniques which improve productivity. To this end it assists research associations and other trade and industrial organizations in applying scientific methods to problems arising in managerial and industrial practice, and its services are given free for the specific purposes of acquiring case material, demonstrating techniques and holding appreciation courses. More than 1,000 men from middle and top management in a wide range of industries have already attended the special courses for management, more than 150 the work simplification courses, and 50 the seven courses in decision-making techniques.

Location of Industry

NEARLY two-fifths of the people in Great Britain live in one or other of seven large conurbations, and during the past thirty years population has grown rapidly on the edges of these conurbations or in districts round about them. Rural areas, on the other hand, have continued to lose population, and even good farming regions, notably parts of East Anglia, have suffered. These trends have given rise to important contemporary problems of congestion, soaring property values and pressure on open spaces, not forgetting the lengthening of the commuter's journey. The greatest expansion in population has been in South-East England. Birmingham and London, in particular, have been the major foci for growth and development. Greater emphasis on foreign trade has increased the attractiveness of locations which provide good opportunities for access abroad, and the advantages of the South-East would be increased if a Channel tunnel or bridge were constructed. In a broadsheet entitled *Location of Industry*, issued by Political and Economic Planning, Mr. Michael Chisholm argues that the existing machinery for planning industrial location needs overhaul and that the economic climate of the regions should be so adjusted that economic forces can be harnessed to social ends (*Planning*. Vol. 28, No. 466; 29 October, 1962. Pp. 323–366. London: Political and Economic Planning, 1962. 5*s*.). The increasing scale of manufacture and improved communications are giving industrialists a greater choice of location within those general areas that provide good market access. He suggests that many "foot-loose" industries could be attracted to the older, less fortunate areas if they were thoroughly renovated. Much of the social capital (houses, schools, public utilities) in the older areas has outlived its time and is, in fact, often a liability. What is wanted are improved amenities and development in these older areas.

The National Institute of Sciences of India

THE Year Book of the National Institute of Sciences of India for 1961 includes, besides the report of the Council for the year ended March 31, 1961, in which the Institute celebrated its Silver Jubilee and the number of Ordinary Fellows was raised from 350 to 400, brief reports on the work carried out by the Research Fellows, of whom seven senior and nine junior were appointed during the year. The Year Book also lists members of Council, senior staff, Fellows, Committees, and includes an account of the foundation of the Institute as well as its rules and regulations and the accounts for the year (Pp. viii+247. New Delhi: National Institute of Sciences of India, 1962).

The Office of Health Economics

LACK of information about the economic aspects of medical care makes it difficult to run medical and other social services in the best interests of the patient and the State. To help fill this need, the Office of Health Economics has recently been founded by the Association of the British Pharmaceutical Industry. The director is George Telling-Smith. The Office will investigate the economic aspects of health problems, commission original research investigations and reports, collect and collate information on experience in other countries and publish a series of papers based on these inquiries. It will have an advisory panel of independent experts and hopes to receive the support of individuals and professional bodies who are interested in the problems of health economics. The first paper issued by the Office, *Progress Against Tuberculosis*, forecasts the disappearance of tuberculosis as a cause of death in Britain by 1975 if present trends continue and if there is no relaxation of the two-pronged curative and preventive attack on the disease (Pp. 23. London: Office of Health Economics, 1962. 2*s*.). Until 1939, available treatment did no more than delay the fatal outcome, but since then the introduction of the new anti-tubercular drugs has revolutionized treatment. In a preface, Prof. D. Dunlop, Department of Therapeutics and Clinical Medicine, University of Edinburgh, points out that the economic benefit to England and Wales resulting from the use of the anti-tubercular drugs alone is approximately £55 million a year, or more than half the cost of the expenditure of the National Health Service on all drugs to treat all disease.

Mental Health and Disease in General Practice

Two recent publications of the General Register Office deal with different aspects of morbidity. The first, *Supplement on Mental Health*, has become a permanent feature of the Registrar-General's publishing programme, and the present volume is the sixth of the series (Pp. vii+88. London: H.M.S.O., 1962. 7*s*. 6*d*. net). It contains new tables showing sex and age distribution of patients admitted to mental hospitals, and deaths and discharges by age at admission and duration of stay in hospital. The number of patients in mental hospitals, which stood at 148,000 in December 1954, had fallen to 138,000 in 1958 (or 142,000 if informal patients were included) and to just less than 140,000 in 1959. At the same time, direct admissions have risen steadily and in 1959 stood at 106,000 compared with 72,000 in 1954 and 59,000 in 1951. Information is provided about rates of admission and duration of stay for various groups of mental disease. *Disease in General Practice*, the third volume of the *Morbidity Statistics from General Practice* (*Studies on Medical and Population Subjects*, No. 14. By the Research Committee of the Council of the College of General Practitioners. Pp. v+144. London: H.M.S.O., 1962. 16*s*. 6*d*. net), brings together some of the results of the earlier two volumes in essays on different aspects of illness written in narrative form by some of the practitioners who took part in the survey. There is no new material which has not previously appeared, but it is hoped that the form of presentation will appeal to those interested in the subject, who are not statistically minded, and particularly to readers who are concerned with the training of students of medicine.

The Teaching Problem in Britain

IN a pamphlet, *Revalue the Teacher!*, the National Union of Teachers outlines the case for a substantial increase in the salaries of teachers, emphasizing the overall shortage of teachers, as well as the shortage of honours graduates in teaching (Pp. 16. London: National Union of Teachers, 1962). While the pamphlet answers a few of the arguments and quotes freely from the Crowther report, it does not attempt to deal with the difficulty of differential salaries, the serious loss of women teachers, and the problem of part-time employment and other measures require to ensure the most efficient use of highly trained professional men and women—a problem that becomes the more important as their salaries are raised. A good case is well presented, which would be strengthened by evidence of more flexibility and more vision and of recognition that teaching is, above all, a vocation.

The Teaching of Biology

In his inaugural lecture at the University of Leicester, Prof. H. C. Kornberg, professor of biochemistry, first discussed the unity of life and then went on to examine the implications in the present provisions for biological education (*The Unity of Life*. Pp. 21. Leicester: The University Press, 1962. 3*s*.). The subdivision of living organisms into bacteria, plants and animals rests on the differences which are emphasized in their academic study. In consequence, universities in general tend to train specialists in one or two of these branches of the life sciences and, in order to gain admittance to the universities for their pupils, schools adopt the same procedure. There is from the outset a fragmentation of biology, which will become more severe as new biological specialties arise. The multiplication of specialties will face the would-be student of biology with an increasingly bewildering multiplicity of degree courses, all of which will inevitably tend, more and more, to overlap one with another. If this trend continues, it is not inconceivable that students might ultimately graduate with a detailed knowledge of biophysics, biochemistry and molecular biology but with only a hazy knowledge of what plants and animals look like. This multiplication of specialties, with the concomitant tendency to create a corresponding multiplicity of specialist departments, will also impose an increasingly severe strain on the universities themselves, with the result that the smaller universities, at least, may soon find themselves unable to provide the staff, space and equipment necessary to accommodate this mushroom growth. These dire tendencies can be reversed if, in the future development of biology, the present divisions based on the differences between living organisms are complemented by academic units based on the fundamental similarity of life processes. This might find its physical expression in the creation of schools of biological science which might house, under one roof, the specialties which operate at the cellular and functional level at which a unitary approach has already been achieved.

Standardization of Reporting Dental Diseases and Conditions

It has been realized for a long time that in any medical examinations carried out for comparative purposes the most careful standardization is necessary, and this involves control of such factors as the method of examination and the exact definition of diagnostic criteria. This is a particular problem in the field of dental epidemiology, because of the difficulty in defining the threshold levels at which it is considered that undoubted dental or gingival pathology is present. A recent report issued by the World Health Organization is concerned with establishing definitions and criteria for measuring the prevalence of dental caries, gingivitis, periodontal disease, dento-facial anomalies, tooth eruption, and prosthetic requirements (Technical Report Series No. 242. *Standardization of Reporting Dental Diseases and Conditions*. Report of an Expert Committee on Dental Health. World Health Organization, Geneva, 1962). The criteria are simple and well defined; and it is emphasized that the methods recommended are mainly for large-scale studies of differences between populations. If finer comparisons have to be drawn the Committee considers that refinements can be added to the basic data according to the requirements of the particular investigation. There is also a brief section on the planning, reporting and writing of results and examples of dental survey forms. The report fulfils its stated purpose very well and represents a useful contribution to the advancement of dental epidemiology.

Natural History Museum in Alma-Ata

I. G. Galuso, V. S. Bazhanov and T. N. Nurumov (*Priroda*, 3, 62; 1962) provide a brief description of a new Natural History Museum in Alma-Ata, the capital of Kazakhstan. It contains more than 2,500 exhibits in the fields of geology, botany and zoology, and its aim is to represent all the varied nature of Kazakhstan. The Museum was built and organized by the Kazakh section of the U.S.S.R. Academy of Sciences.

The British Museum (Natural History): Recent Acquisitions

Among the more important and interesting items recently acquired by the British Museum (Natural History) is a collection of young stages of British grasshoppers (Acrididae), presented by Prof. O. W. Richards and Miss N. Waloff. It is unique, comprising about 1,000 specimens in spirit, including every nymphal instar of all ten British species. The Department of Entomology has also been presented with 242 slides of Streblidae, the major part of the unique collection of Mr. Boris Jobling, of the Wellcome Foundation.

The Bernice P. Bishop Museum

Under the attractive title of *Science and Education* and with an arresting format, the activities for 1961 of the Bernice P. Bishop Museum in Honolulu are described in a far from formal manner (Pp. 29. Honolulu, Hawaii: Bernice P. Bishop Museum, 1962). The chief event was the completion of Kilolani—the Hawaii Planetarium and observatory. This was the climax of eight years of planned improvement of educational facilities of the Museum. Kilolani consists of three separate but connected units. The first is an appropriate entrance exhibit gallery, then the Planetarium proper, seating about 100 visitors and equipped with a Spitz instrument. The third unit is an observatory containing a 12·5-in. reflecting telescope, but capable of accommodating a larger instrument if this proves desirable in the future.

U.S. Federal Aid in Wildlife Restoration

The Federal Aid in Wildlife Restoration Act was approved in September, 1937, and popularly known as the Pittman–Robertson Act. It was designed to help check the depletion of the wildlife in the United States and stimulate its restoration. Since wildlife is a product of the land, its restoration depends on providing suitable living conditions for the desirable species. The developmental work that favours the increase of wild birds and mammals contributes also to the conservation of soil and moisture, which are essential to the maintenance of a prosperous agriculture. The income from the sale of hunting and fishing licences is practically the only revenue available to finance the activities of State fish and game departments. Lack of adequate funds in the past prevented the conducting of much-needed restoration work. Under the Federal Aid in Wildlife Restoration Act, funds are made available to the States for co-operative programmes to increase wildlife populations, to procure information through field studies for improving the management of this natural resource, and to provide an annual surplus of game birds and mammals to be collected by hunting and trapping. The Act provides that the United States may pay 75 per cent of the cost of work performed on approved projects. Projects are confined to the purchase and development of lands, the restoration of natural environment, the maintenance of completed projects and the management of wildlife areas and resources (United States Department of the Interior: Fish and Wildlife Service. Bureau of Sport Fisheries and Wildlife. Regulatory Announcement No. 64: *Federal Aid in Wildlife Restoration*. Pp. 21. Washington, D.C.: Government Printing Office, 1962. 15 cents) (see also p. 1134 of this issue of *Nature*).

Wildfowl Research and Conservation

THE typically attractive report of the Wildfowl Trust for 1960–61, by Hugh Boyd and Peter Scott, is important for a number of accounts designed to show what has been happening in various parts of Europe with regard to wildfowl research and conservation (Pp. 204 + 65 photographs. Slimbridge: The Wildfowl Trust, 1962. 17*s*. 6*d*. net). The general picture emerging is that, in the field of conservation, legislation restricting shooting and other forms of destruction is now fairly severe. Continued reduction of 'shooting pressure', where this may be found necessary, is likely to call for improvements in the enforcement of existing legislation and for self-education and restraint by wildfowlers, rather than for further extensive restrictions. The pressure on wildfowl exerted by the continued loss of wetlands, offset to some extent by the construction of new reservoirs, cannot be relieved in any simple way. It calls for constant vigilance, for the early detection of major threats, and for dogged but not unreasonable resistance to changes which are unnecessarily harmful. Though this is certainly an international problem, shortly to be discussed at a full-scale European conference, it is also one against which people whose concern is primarily local can protest more effectively. It is to be regretted that the international problem of oil pollution of navigable waters has not been solved. The Trust and related organizations have no shortage of important and fascinating problems for investigation, but there are few people to carry them out—there are fewer than forty biologists in the whole of Europe able to give a substantial part of their time to research on wildfowl. Yet, in relation to the work which has to be done, the need for more workers is even more important and urgent in the practical application of research, in education and the other tasks of conservation. It is gratifying to read of the increased number of visitors to the Trust's collections at Slimbridge and Peakirk.

The Society for the Promotion of Nature Reserves

IN several ways 1961–62 was remarkable in the history of the Society for the Promotion of Nature Reserves. Early in the year the Nature Conservancy was enabled, through a grant of £1,500 from the Society, supplemented by £500 from a generous donor, to acquire 123 acres of downland at Wye and Crundale in Kent as a National Nature Reserve. The reserve lies on the southern escarpment of the North Downs and is an excellent example of the product of long-continued grazing by sheep. It is cut into deeply by the conspicuous Devil's Kneading Trough. Entomologically and botanically, the area is of considerable interest. The year saw a further impressive expansion of the County Naturalists' Trusts' movement. New Trusts were established in Gloucestershire, Northumberland and Co. Durham, the Lake District, Cornwall and Shropshire, and the process of formation was started in Wiltshire, Cheshire, Lancashire, Hertfordshire and Middlesex. In Northamptonshire, Nottinghamshire, Herefordshire and Somerset, discussions about forming Trusts are going on, and within eighteen months almost every county in England, and possibly Wales, should be covered by a Trust. To the Society's co-ordinating and advisory functions has now been added the important responsibility of acting as a channel for the Trusts' applications for financial aid to the Society, the World Wildlife Fund and the Nature Conservancy. Full details of its activities are available in the forty-fifth annual report of the Society for the year ended March 31, 1962 (Pp. 64. London: The Society for the Promotion of Nature Reserves, British Museum (Natural History), 1962. 10*s*.).

The Lake District

THE case for resisting encroaches on the amenities of the Lake District is eloquently pleaded in the July issue of the *Report and Newsletter* of the Friends of the Lake District (Pp. 21. Ulverston: Friends of the Lake District, 1962). Of recent attempts to remove more water from the Lakes, the society contends that no more water should be taken away until it has been established beyond all doubt that the consumers who need water cannot be supplied from sources outside the National Park. The society offers total and determined opposition to the damming of lakes and the flooding of valleys, and to the heightening of existing embankments on such lakes as Crummock Water or Ennerdale. If further water has to be taken from Lake District sources, then the method of intakes in the lower courses of rivers (that is, below the respective lakes), with or without pumping, is that least injurious, always providing that the interests of agriculture and of communities lying downstream are safeguarded by the reservation of adequate compensation water. That the Lake District sources could be developed more cheaply by more ruthless methods is not sufficient argument for their adoption. For cheapness must not be the chief criterion. The values that National Parks exist to serve must be given their full weight in the equation; neither considerations of mere convenience nor money values should be allowed to become the deciding factors. The *Report and Newsletter* also records the public-spiritedness of the North-Western Electricity Board which, despite approval from the Minister of Power, changed its policy with regard to a long stretch of overhead mains and decided, at its own expense, to put them underground.

Handa Island Nature Reserve

THE Royal Society for the Protection of Birds recently announced an important new reserve on the uninhabited island of Handa, off the west coast of Sutherland (*Council for Nature. Intelligence Unit*, 30, August 1962). The proprietors have made an agreement with the Society to manage this magnificent sea-bird colony as a nature reserve and bird sanctuary. Puffins, razorbills, common and black guillemots, fulmars, shags, kittiwakes and herring and great black-backed gulls all breed there. A grant from the Helena Howden Trust has enabled the Society to repair and furnish the bothy on the Island to provide accommodation for up to six members wishing to stay there to watch and study the birds. Bookings should be made through the Society's Scottish Office, 21 Regent Terrace, Edinburgh 7. Access is by fishing boat from Tarbet or Scourie, and there are no restrictions on landing.

The Lundy Field Society

THE fourteenth annual report of the Lundy Field Society includes a list of the birds recorded during the year, the species ringed during 1959, 1960 and 1961, and some interesting ornithological notes on the more unusual observations (Pp. 40. Barnstable: Hon. Secretary, Lundy Field Society, 8 Rock Avenue, 1962). It is also of importance to note that fourteen recoveries have been made of ringed birds, two having reached the U.S.S.R. There is a preliminary account of the archæological investigations in the "Bulls Paradise" by Mr. K. S. Gardner and a report on the discovery of the 'Tulocus' Stone in Beacon Hill Cemetery.

The International Congress of Mathematicians (Edinburgh) Fund

THE British National Committee for Mathematics has been asked by the Trustees of the International Congress of Mathematicians (Edinburgh) Fund to allocate grants from the Fund for the following purposes: (*a*) award of travel grants to mathematicians in the United Kingdom to attend international conferences; (*b*) donations to mathematical symposia, meetings or conferences to be held in the United Kingdom. Applications in respect of (*a*) should be made on forms of application obtainable from the Executive Secretary of the Royal Society (Burlington House, Piccadilly, London, W.1). Applications in respect of (*b*) should be submitted by letter to the Executive Secretary of the Royal Society, supplying the following information: (i) name and address of sponsoring organization; (ii) details of proposed scientific meetings: (*a*) place, (*b*) dates, (*c*) total amount of financial assistance required; (iii) brief statement of scientific programme of the meeting including principal speakers; (iv) exact purpose for which grant is required (giving estimates with details where possible); (v) whether the applicant has applied for assistance from any other source and, if so, with what results. Applications in respect of (*a*) or (*b*) should be sent to the Executive Secretary by December 31.

The Cement and Concrete Association's Training Courses

THE Cement and Concrete Association has issued its prospectus and programme, *Training Courses in Concrete*, for 1963. The Association's courses, held at their Training Centre and Research Station at Wexham Springs in Buckinghamshire, are well known as an integral part of the training of those concerned with the design, making or placing of concrete. The programme of courses offered in 1963 follows a similar pattern to previous years, but a new feature is the appearance of two combined courses and overseas visits, one for architects, the other for engineers concerned with motorway and major road construction. Participants on these courses will spend two days at the Training Centre and the remainder of the week visiting outstanding jobs on the Continent. Copies are obtainable from the Training Centre, Cement and Concrete Association, Wexham Springs, Framewood Road, Stoke Poges, Slough, Bucks.

Announcements

DR. E. M. PATTERSON, senior lecturer in mathematics in the University of Aberdeen, has been awarded the Makdougall Brisbane Prize for the period 1960–62 by the Royal Society of Edinburgh, for his papers on linear algebras published in the *Proceedings* of the Society during the period of the award and earlier papers on cognate subjects published by the Society.

ENTRIES are invited for the 1963 Maccabaean Prize of 25 guineas and a bronze medal, which is awarded annually by the Faculty of the History of Medicine and Pharmacy of the Worshipful Society of Apothecaries of London. Competitors, who must be under thirty years of age on March 15, 1963, will be required to submit before that date an essay of not more than 6,000 words on any subject connected with the history of medicine or pharmacy. Entry forms and further information can be obtained from the honorary secretary of the Faculty, Dr. F. N. L. Poynter, the Wellcome Historical Medical Library, the Wellcome Building, Euston Road, N.W.1.

THE eleventh inter-university geological congress on "Geological Aspects of Commonwealth Economy" will be held at University College, Cardiff, during January 3–5. Further information can be obtained from K. Howells, Department of Geology, University College, Cathays Park, Cardiff.

A SYMPOSIUM on "The Evaluation of the Degree of Hydrogen Bonding in Biological Molecules", supported by the British Biophysical Society, will be held at the South-West Essex Technical College and School of Art, Walthamstow, on February 16. The opening lecture will be delivered by Prof. J. A. V. Butler. Further information can be obtained from Dr. S. Lewin, South-West Essex Technical College and School of Art, Forest Road, Walthamstow, London, E.17.

POSTGRADUATE courses in "Inorganic Stereochemistry" and "Nuclear Metallurgy", suitable for graduates and research workers in the fields of chemistry and metallurgy, will be held at Brunel College. The first course will consist of seven lectures to be given on consecutive Mondays commencing on January 14, and the second of nine lectures, to be given on consecutive Thursdays commencing on January 10. The fee for each course will be £1. Further information and forms of application can be obtained from the Registrar, Brunel College, Woodlands Avenue, Acton, London, W.3.

THE fourteenth Pittsburgh conference on "Analytical Chemistry and Applied Spectroscopy" will be held in Pittsburgh, Pennsylvania, during March 4–8. The programme will include symposia on: solution techniques in X-ray and emission spectroscopy; techniques related to infra-red spectroscopy; nuclear magnetic resonance—nuclei other than hydrogen; gas chromatographic analysis of metallo-organics and related compounds; uses of reaction-rates in analytical chemistry; the analysis of refractory metals. Further information can be obtained from the programme chairman, Dr. W. A. Straub, Applied Research Laboratory, United States Steel Corporation, Monroeville, Pennsylvania.

THE VEGETABLE AND GLASSHOUSE RESEARCH STATION, IRELAND

By Dr. DIARMUID MURPHY

ON September 20, Mr. Sean Lemass, Taoiseach (Prime Minister) of Ireland, opened the Vegetable and Glasshouse Research Station of An Foras Taluntais (Agricultural Institute), Kinsealy, Malahide, Co. Dublin. Mr. John G. Litton, chairman of the Council of An Foras Taluntais and Dr. T. Walsh, director, welcomed An Taoiseach to the Station. The opening was attended by members of the Council of An Foras Taluntais, senior staff members and 150 guests.

Kinsealy is in the centre of the vegetable growing area of North County Dublin, and An Foras Taluntais acquired 150 acres in the area in 1959. The farm is 70 ft. above sea-level and is about 8 miles from Dublin. The solid geology consists of pale grey, coral reef limestone, overlain by gravelly boulder drift of predominantly limestone composition deposited by ice during the Weichsel glaciation. 90 per cent of the soil on the farm is a well-drained loam to clay loam texture of high base status. Available phosphorus-levels are moderate, but available potassium-levels are low (due to fixation by large amounts of illite).

The station serves as the headquarters for the Horticulture and Forestry Division. In addition, the following Departments of other divisions of An Foras Taluntais have research facilities at the station: Soil Physics (Soils Division); Cereal Chemistry and Nematology (Plant Sciences and Crop Husbandry Division). Staff of the National Soil Survey and of the Plant Nutrition Department (Soils Division) use Kinsealy as a centre of operations, and the Grassland Management and Animal Physiology Departments (Animal Production Division) also conduct experimental work at the Station. The following buildings are now complete: the main laboratory and administrative block, the glasshouse and propagating unit, the boiler unit, and the nematology unit. It is proposed to build a mushroom research house.

The main laboratory and administrative block contains a library and assembly hall (570 sq. ft.), canteen to seat 50, administrative offices (2,200 sq. ft.), and laboratories for cereal chemistry (2,040 sq. ft.), soil physics (2,380 sq. ft.), horticultural chemistry and biochemistry (2,720 sq. ft.), plant pathology (1,100 sq. ft.) and mushroom research (850 sq. ft.). In addition, there is a workshop, storage space, dark room and provision for growth rooms.

The main laboratory building runs north–south with the main entrance in the middle. The library and conference hall are over the main entrance, making for ease of access for lectures or conferences. A corridor runs the length of the building with laboratories and offices opening off. The building was originally planned as a single story structure but due to the topography of the site it was found more desirable to build a semi-basement under the North Block, thereby increasing the available floor space by almost 50 per cent. The entire building, which is 310 ft. long by 42 ft. wide, is planned on the modular principle, 10 ft. being the standard module width. The depth of the laboratories is 17 ft. 6 in. Adequate office space separate from the laboratories has been provided for graduate staff.

The glasshouse unit consists of 13 houses, each 100 × 30 ft., and two propagating houses, 75 × 20 ft. One of the glasshouses is designed as a lysimeter house, allowing exact nutritional and moisture studies on a wide variety of plants. It is proposed to build more glasshouses in order to extend the research programme.

A boiler-house serves the entire heating needs of the glasshouses and laboratory buildings. The main boiler uses compressed peat briquettes and is the first completely automatic peat-burning boiler in Ireland.

Because of the nature of the work involved, the nematology laboratory (2,560 sq. ft.) has been placed at a distance from other buildings. It is planned for a smooth flow of work and contains the following rooms: soil reception, drying, extraction and microscope rooms, plus offices, research laboratory and dark room.

The greater part of the research effort at Kinsealy is on horticultural crops, under two headings: vegetable crops and glasshouse crops. A great deal of information is still lacking on the needs of vegetable crops as regards climate, soil suitability, varieties, husbandry methods and nutritional requirements

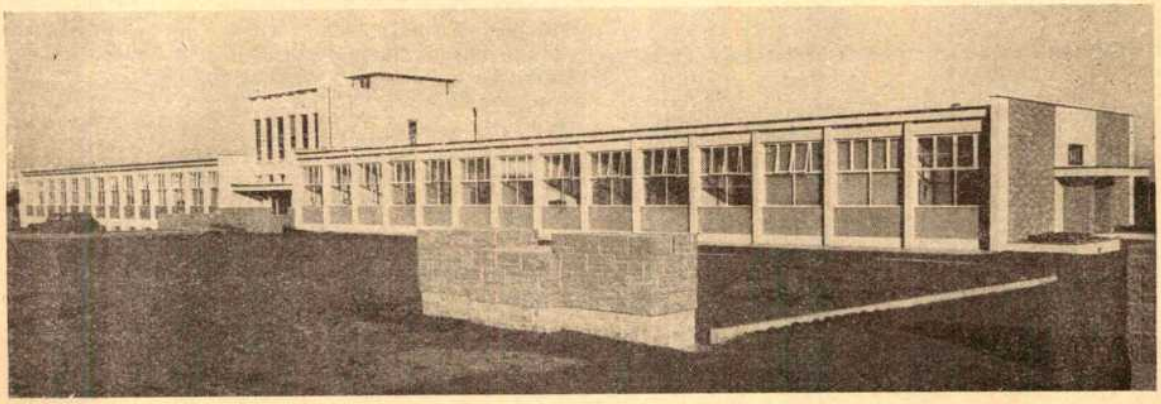

Fig. 1. New research laboratory and administrative building at Kinsealy, Co. Dublin

under Irish conditions. All the common vegetable crops are being grown in a series of field trials. Aspects also being investigated are variety breeding (with emphasis on new varieties suitable for packaging and processing), and weed control.

The glasshouse vegetable work is at present concentrated on tomatoes, cucumbers and lettuces. Already valuable information has been obtained on methods of extending the tomato season. Flower crops under glass are also being examined so that information may be gained which will enable growers to cater for the home and export market.

The Chemistry and Biochemistry Department serves the needs of the vegetable and glasshouse crops sections and a comprehensive research programme is being developed, including work on manurial and trace element problems. It is proposed to build up a large laboratory programme dealing with the chemical and biochemical factors of 'quality' in fruit and vegetables. In addition, work is being done on the chemical aspects of Irish honey—a product capable of great development.

The mushroom research unit is concentrating on the cytological and genetical aspects. A close liaison is maintained with growers and many problems of a practical nature have received attention. To supplement the research facilities at Kinsealy a production unit is available at another centre of An Foras Taluntais. It is proposed to erect a commercial-scale mushroom house at Kinsealy.

A feature of the research work which is of special practical value is that, due to the nearness of the Dublin market, test marketing projects can be carried out on vegetables and flowers in conjunction with the Rural Economy Division of An Foras Taluntais.

The work of the Soil Physics Department deals with research in soil texture and structure, and drainage. The Department also uses Kinsealy as a centre from which soil studies are conducted at a number of other stations. Facilities provided include equipment for soil mechanics and physics, and soil moisture studies. Particular attention is being paid to the water requirements of a number of vegetable crops. In addition, the lysimeter house provides facilities for accurate water balance studies.

The Cereal Chemistry Department has a comprehensive research programme on both the applied and fundamental aspects of wheat and other cereals. Equipment includes drying facilities for 50 samples simultaneously, Brabender grain cleaner, Buhler semi-automatic mill, dough-testers (Brabender farinograph and extensograph) and complete experimental bakery. Factors such as yield, early maturity, resistance to sprouting (of fundamental importance in Ireland because of high rainfall), milling and baking quality, and protein content of wheat are under investigation. Studies on malting and feeding barley are proceeding, and studies on oats are projected.

The Nematology Department undertakes such work as the study of bionomics, host-range and economic importance of eelworms and population studies of eelworms. An important aspect of the work is certification and quarantine of seeds and plants. Other work undertaken includes search for resistant plant varieties, and testing the mode of action and efficiency of nematicides under Irish conditions.

While the research station at Kinsealy is comparatively young, it presents a unique opportunity for co-operation between research workers of many disciplines. As a result of the research programme in hand, much information has already been gained and has been made available to the horticultural and agricultural industry in Ireland.

NUCLEAR CHEMISTRY

An informal discussion on nuclear chemistry, organized by the Atomic Energy Research Establishment, Harwell, was held in the Inorganic Chemistry Department at the University of Oxford during September 18–21. The meeting followed similar discussions previously held, at the University of Durham in 1960, and at CERN, Geneva, in 1961. On this occasion the subject was "Fission and other Low Energy Nuclear Processes". Sixty-one papers were presented covering fission, spallation, radioactive decay; the energy released in these processes; and the general techniques for observing them. Abstracts of the papers have been published as a Harwell memorandum number *AERE–M* 1078, but in view of the informal nature of the meeting no other record has been made. About 180 delegates attended, representing fifty different laboratories in Europe and the United States.

In the opening paper W. J. Swiatecki (University of California) described recent developments in the liquid drop model of the nucleus, and these were applied by T. Sikkeland (Berkeley) to his work on fission induced by heavy ions. Here the compound nuclei formed by the interaction of heavy ions carbon-12 and oxygen-16 on targets from praseodymium-141 to plutonium-240 cover a wide range of charge to mass ratios. The kinetic energy released was shown to agree closely with detailed predictions of the liquid drop model. In the course of the discussion it was pointed out that the fission energy, which arises from the coulomb repulsion of initially contiguous nuclei, is extremely sensitive to the shape of the nuclei, and provides a valuable means for studying nuclear deformation.

S. G. Thompson (Berkeley), R. H. Tomlinson (McMaster University, Canada), and R. Vandenbosch (Copenhagen) all reported experimental support to the theoretical picture that at fission one fragment tends to assume a closed shell configuration, whereas the other fragment is more deformable, takes up excitation, and emits neutrons.

Discussion on fission yields concentrated mainly on the relative amounts of isomers of different spin. Radiochemical measurements of the yields of the isomers reported by I. F. Croall (Atomic Energy Research Establishment) implied that the initial fragments were of high angular momentum, and this conformed with the measurements of the directional correlation between prompt γ-rays and primary fission fragments reported by M. M. Hoffmann (Los Alamos).

Perhaps the most important contributions to the meeting were those on semi-empirical mass formulæ based on the new tables for nuclear masses recently published by Everling, Koenig, Mattauch, and Wapstra. H. Kummel (Max-Planck Institute, Mainz) accounted for the systematic trends in the masses of all known nuclei to an accuracy of 1 MeV by the use of fifty parameters. W. J. Swiatecki showed that the major trends in the deviations of the masses and shapes of nuclei, from those predicted by a liquid drop formula, could be accounted for in a rough way on the basis of a semi-empirical expression with three parameters. These new formulæ should make possible a better assessment of the mass and energy balances in fission which, as discussed at the meeting, are seriously wrong for uranium-235 and plutonium-239 fission on the basis of the old mass formulæ.

In the session on spallation, K. F. Chackett (Birmingham) interpreted his results from (p,n) reactions on the basis of the optical model of the nucleus, and N. Lefort (Paris) described proton reactions in terms of α-particle structures in the nucleus. G. R. Martin (Durham) reported cross-sections for $(n,{}^3\text{He})$ reactions, and for (n,pn) processes; the latter seemed to agree well with a 'direct interaction model', rather than with an evaporation mechanism. Again, the excitation functions of $(d,2n)$ reactions reported by L. J. Gilly (Louvain) failed to agree with predictions of neutron evaporation from compound nuclei. In discussion the general view was expressed that for spallation phenomena the theoretical background is at present very inadequate.

Among the papers on radioactive decay some new isotopes were reported, notably radon-223 (half-life 39·8 min.) and radon-224 (114·8 min) by V. J. Robinson (Liverpool). A paper was given by J. Maly (Dubna) on a new method for the preparation of mendelevium by the bombardment of uranium with neon ions, and some details of the chemistry of this element were reported for the first time. Interesting accounts were given of activation processes (M. Lindner, Livermore), and of the production of transuranic elements (J. D. Knight, Los Alamos), in underground nuclear explosions.

The session on chemical effects was restricted to studies in which different nuclear events could be compared. A. G. Maddock (Cambridge) compared the condition of chromium-51 formed by the (n,γ) process on chromium-50, with its condition when formed by the $(n,2n)$ process on chromium-52 in solid potassium chromate. While no significance could be seen in the initial retention, the subsequent annealing of the material formed in the more highly energetic $(n,2n)$ process was shown to be slower than the annealing of that from the weaker (n,γ) process. In subsequent papers by I. G. Campbell (Manchester), L. Lindner (Amsterdam), and G. E. Miller (Oxford), the importance of the annealing or recombination processes was again emphasized. In the discussion attention was directed to the pressure effects which may influence the 'rigidity' or 'softness' of crystal structures in solids, and 'cage' effects in liquids. Four papers were given on the effects of fission recoil, and in discussion particular attention was given to the sputtering processes that occur when fission fragments pass through surfaces.

In sessions on techniques consideration was given mainly to the problems of flux monitoring. In particular the accurate measurement of reactor neutrons by cobalt activation was described by T. A. Eastwood (Chalk River, Canada) and of neutron spectra from cyclotron targets by A. H. W. Aten, jun. (Amsterdam). New methods for conducting fast chemical separations for measuring short-lived radionuclides were also described. For example, G. Herrmann (Mainz) showed that thin layers of fresh crystalline precipitates on filters retain a large fraction of their own and related ions from solutions filtered rapidly through them. The most notable advance in recent years in radiochemical techniques for the analysis of mixtures of radioactive isotopes is the use of a mass separator in which the relative amounts of the activity on the different target areas where the different nuclides are deposited is measured. Papers by G. Andersson (CERN), and T. A. Eastwood, described this technique, and a third paper was given by H. Ewald (Munich) on the application of a similar technique to the mass separation of highly charged fission fragments during their formation. A refined method for the measurement, by mass spectrometry, of stable fragments (lithium-6 and lithium-7) formed in high-energy proton irradiations was described by E. Gradsztajn (Orsay).

The meeting concluded with descriptions and comparisons from Livermore and Aldermaston of the computer programmes used in the large-scale analyses of radioactive decay data. G. N. WALTON

FUTURE OF TEACHING MACHINES

PROF. B. F. SKINNER, of the Department of Psychology, Harvard University, delivered an address on "The Future of Teaching Machines" on October 19 in the University of Oxford, at the invitation of Prof. R. C. Oldfield. Prof. Skinner began by commenting on the present state of confusion in this field, which is now barely eight years old. This confusion was partly due to commercial interest in producing programmed texts, partly to the enormous growth in the needs of education, with ever more students to be taught and ever more to teach them, and partly to the activities of 'gadgeteers' who delighted in inventing a variety of devices which could be referred to as 'teaching machines' but which were not based on a knowledge of the learning process.

Though education is often considered a preparation for the real world, it is difficult to bring the real world into the classroom; consequently, education has in practice mainly concerned itself with setting up verbal repertoires of one sort or another, teaching the student to speak a language, to perform mathematics, essentially a verbal procedure, or to command the facts of a science. The first learning machines which had been developed in his department had similarly been directed to the development of verbal skills. They required the student to fill in a missing letter in a word, a word in a sentence, or a term in an equation; if right, the student moves on to a new frame; if wrong, he must try again. In this way he works through the programme. Present-day programmes advance by very small steps, so that students make few errors and very little repetition is required. Though the material seems very simple the students move on to advanced technical material very rapidly. The students in his course at Harvard spent their first month using the machines in the 'self-instruction room'. At the end of that period he could lecture to them secure in the knowledge that they had mastered the technical material necessary for the course.

Two effects of the use of these machines were worthy of note. The first was the improvement in the pupils' motivation which they produced. In most schools children studied because they did not dare do otherwise; but children using the machines became absorbed in the work. He had visited an eighth-grade class in Roanoke engaged in studying a programme on algebra in an experiment by Dr. A. Calvin. Not a head was raised from a machine while he wandered through their classroom talking to their teacher. In Toronto an experiment came awry because the children would not restrict their studying to the prescribed hours but smuggled the programmed text (on English grammar) out of school for further study. The children became confident and interested; on returning to ordinary teaching methods they were alert and ready to offer comments. The second effect depended on the fact that the machine allowed each student to go at his own pace. It has been said that what would astonish Plato most to-day is that we attempt to teach two students at the same time. One result of teaching large numbers at the same rate is that the slow student cannot keep up and rationalizes his failure. Yet there is no evidence that the slow student cannot do first-class work if he is given the time to do it. In one experiment, by Dr. D. Cook, an 800-frame programme on chemistry was presented to a class whose intelligence quotients ranged between 100 and 140. It was found that the least intelligent children took approximately twice as long to finish the programme as the brightest, but when tested at the end there was little difference in their achievement scores. Given enough time it appeared that the slow student could do as well as his swifter colleague.

The basic experimental research which had allowed the development of this new sort of educational technology was then discussed. This had relied not on statistical surveys but on the intensive study of individual organisms with a view to analysing the effective environmental factors and developing the ability to predict behaviour from a knowledge of the environment. It had been found that the contingencies of reinforcement had an extraordinary power to select and control behaviour. This was illustrated by a classroom experiment in which the class chose the behaviour, such as bowing, tracing a circle, or leaning over backwards, which they wished a pigeon to perform, and this was produced in a few minutes solely by governing the intermittent food reinforcement given it. At first the experimenter rewarded behaviour corresponding within liberal limits to that required; when the animal repeated this the reinforcement would be made conditional on a more exact correspondence to the prescribed behaviour. More complex reinforcement contingencies could not readily be produced by hand but required special apparatus. This set environments in which certain behaviours would develop. In one sense these devices were teaching machines.

One problem was whether learning could be produced if the animal never made an error; it had been shown experimentally that this was possible. In an experiment by Dr. H. Terrace the aim had been to train a pigeon to discriminate between a pattern of horizontal lines and one of vertical lines without ever having made the error of pecking at the vertical lines. Initially the animal was presented with a key in bright red illumination. It pecked at the key and was rewarded, and the illumination was simultaneously removed. When this sharp change has occurred the pigeon does not peck the key again at once. Before it can do so the key again becomes bright red, the pigeon pecks, and is again rewarded. The intervals between illumination of the key can then be gradually increased without the pigeon ever pecking at the key when dark. The next stage was gradually to add a greenish tinge to the dark key, and decrease the brightness difference, until eventually the pigeon was discriminating perfectly between a red and green of equal brightness. The horizontal lines were then superimposed on the reddened key and the vertical lines when it was green, and they were gradually made more salient while the colours were gradually 'vanished', until finally the desired discrimination was being made by an animal that had never made an error. This showed that trial and error was not essential for learning, and it produced a 'bonus': a pigeon trained in this way was completely neutral to the negative stimulus, it did not show the 'emotional' behaviour often found when an animal is confronted with a stimulus which it has frequently pecked without reward.

Some programmes have been produced in which the student makes errors and the programme then produces comments on them. But it seems this is not necessary; programmes can be devised in which very few errors need be made. Prof. Skinner's first attempt of this sort was made when his small daughter was given the task of learning a passage of poetry. He wrote it on the board and she read it through. She then left the room, he erased some letters, she returned and read it through again. After four or five readings there was nothing left on the board but she could still "read it through".

One of the most common criticisms of teaching machines was that they might be useful for rote learning, but that they could not teach a child to think. This was not the case. Actually in practice we did not usually teach thinking; students were presented with problems and we claimed credit for those who solved them. The others were left by the wayside. We most often taught verbally, and when we did not we tended to teach 'final products', for example, to teach driving in a motor-car or flying in a cockpit, real or simulated. If we analysed the process of thinking, and such achievements, we might find that there were basic skills necessary to them which could be taught one by one. A programme designed by Drs. Holland and Long to teach 'inductive thinking' was described. Programmes had been developed for teaching a number of non-verbal skills, and some of the more important developments of the future might lie in this area. Prof. Skinner described a device intended to cultivate a sense of rhythm. This required the child to tap in unison with a presented rhythm. At first very approximate agreement was acceptable, but the limits were gradually decreased until skilled performances were produced. Even professional musicians tested with this apparatus showed unexpected defects, such as a tendency to be just ahead or just behind the presented rhythm, or, very commonly, a tendency to speed up if their performance was good. Another device was being used to teach 'tone-deaf' children to discriminate pitch. Beginning with coarse discriminations they were gradually brought to the point where they could discriminate tones or semi-tones. Without devices such as these it was scarcely possible to provide the differential contingencies of reinforcement which would 'shape' such types of non-verbal behaviour. Eventually we may hope to be able to teach all the basic skills constituting adaptation to the environment, and so to enable man fully to exploit all his potential skills.

THE INSTITUTE OF PERSONNEL MANAGEMENT

A MANAGEMENT conference which, each year, attracts about 1,000 members from home and overseas must surely be a source of considerable attraction. Each year the conference of the Institute of Personnel Management attracts about one-fifth of its members, and the question could fairly be asked about the nature of the attraction. While the good fellowship would draw many to the conference, there is little doubt that the quality of speakers and the relevance of their subject-matter is the main draw. The content of the sectional meetings over the past five years could, indeed, well be compounded to form a useful 'Students' Refresher Guide to the Intricacies of Industrial Relations in Britain'.

This year's conference at Harrogate was held during October 4–6, and was no exception to the general rule. P. M. Uri, director of Lehman Bros., Paris, discussed the role of planning in economic growth and showed that, in those countries where there has been most rapid rate of growth—the U.S.S.R., Japan, Germany, Italy and France—the only truly common denominator has been a surplus of manpower. Planning has been carried out in different ways in different countries, with each one initiating new forms of long-term finance. In France, the planning organization is made up of a Commissariat Du Plan, consisting of three or four people supported by another small group of individuals who act as secretaries for different industrial committees. Apart from this small staff, there are about one or two thousand people around the small nucleus. They are organized in a certain number of committees by industries, plus an overall economic committee which is trying to see what kind of balance can be achieved between total investment, total resources and total sources of finance. The constitution of these committees is partly people from industry, partly people from the administration, partly independent experts, and partly members of the trade unions. This is considered the mainspring of democratic planning and how a plan can be implemented. Such a form of planning has played an important political part, because it has helped to create a conviction about important decisions which had to be reached on the morrow of the liberation. That was a time of utter economic destruction, and two hard decisions had to be reached. One was that the limitation of the working week to forty hours had to be abandoned, and the workers had to be prepared to work longer hours to speed up reconstruction. The second decision was to postpone reconstruction for housing purposes and give priority to the productive equipment of the country. Now the plan may play a different part.

Dr. N. W. D. Beese, works relations officer, Billingham, Imperial Chemical Industries, Ltd., examined the place of employee communications in the building up of good industrial relations. These have to be related to other forms of communication in industrial organizations. They are the day-to-day line management flow of information necessary for the operation of the organization and the exchange of information in joint consultative procedures such as works councils and efficiency committees. The line management and joint consultative channels of communication are first priorities and only when these have been properly organized and are working smoothly is it feasible to embark on an employee information service programme.

At a sectional meeting, some of the ramifications of the so-called wages drift were examined. This is probably a more important cause of inflation than increases in wages which are negotiated nationally. The drift occurs at factory- and office-level when earnings are increased by over-time, various kinds of incentive schemes and fringe benefits. According to K. J. Burton, formerly secretary of the British Employers' Confederation, wages drift is due to the fact that there are no appreciable unused reserves of labour, while there is insidious danger in the failure to recognize that the significance of basic wage-rates as the determinant of earnings and of total labour costs ranges considerably from industry to industry. False comparisons are often made during essential stages in collective bargaining. The remedy is not to weaken collective bargaining arrangements but to aim at greater co-ordination of variations within industries and localities.

Investigations by Dr. M. Jahoda, Nuffield Research Fellow at the Brunel College of Technology, into the relations between industry and technical colleges, showed that, while collaboration between industry and college functions by and large is in a satisfactory manner, there is also a number of general problems. The Hives Council's stipulation, for example, that responsibility be shared between colleges and industry permits in practice a variety of interpretations.

Since, from a company's point of view, education leading to a diploma in technology is expensive (the cost of one student for four years is estimated to be about £2,000), some companies feel that they carry, or should carry, major responsibility, certainly for the industrial periods. Where this view is also held by a college, divided responsibility alternating every six months between college and company is the inevitable consequence. Colleges cannot choose this interpretation, even if they wished to, because the diploma in technology is essentially an academic qualification; the Hives Council holds the college responsible for attesting that a student's industrial training has been adequate. This means that the college must exercise its responsibility in shaping the industrial training periods, preferably by joint agreement on their nature and content before a student begins his training. Shared responsibility is most easily achieved in student selection, which must find the approval of both partners; it is most difficult in arranging the actual practical work of the student.

A further difficulty arises from the fact that by far the most promising technique for integrating practical and theoretical knowledge in the student's mind is the tutorial system. Here, college staff visit the student at his place of work to discuss with him the manner in which his practical experience relates to his academic knowledge. There is still some confusion about the function of the college tutor, both among tutors and in industry. While visits to firms can serve public relations purposes, provide consultation opportunities on technical matters for the company or the tutor, or preferably both, the major object of these visits is to help individual students in achieving integrated knowledge. In the light of experience, the hope of achieving integration by arranging industrial work so that it is an immediate application of what the preceding college period presented theoretically must be regarded as naïve and impractical. The task of integration is made easier where companies appoint industrial tutors to students working for a diploma in technology, who remain a constant focus for immediate technical supervisors.

Jahoda had asked students how they liked their first industrial training period and how much they had learned from it. A combination of answers provides some yardstick for evaluating industrial training. By this yardstick, 64 per cent of students engaged in project work felt they had a good experience; 54 per cent in training schools, 38 per cent working on a technician-level, 31 per cent on a perambulatory course, and 18 per cent on a production worker-level valued the industrial period highly. In spite of the subjective nature of the judgment, these figures indicate some aspects of a successful industrial training period.

The question whether a personnel manager should advise general management on matters of organization structure and the style of operational management was examined by W. G. McClelland, Research Fellow in management studies at Balliol College, Oxford. McClelland indicated that the personnel manager has the responsibility of supplying satisfactory personnel, and, properly to discharge this responsibility, he must be able to analyse what they will be called on to do and what they will get out of it, and to make recommendations designed to ensure that the organization can compete successfully in the labour market. Since requirements and rewards are not merely matters of skill and pay, but are affected by organization structure and style of management, the case for the personnel manager's right to intervene would seem easy to establish. In the case of managerial personnel, most selection consultants insist on analysing the organization before embarking on recruitment and selection.

The personnel manager may also be called on to devise and apply tools of management—such as appraisal forms and training in communications techniques—required as the expression of an inappropriate management philosophy or to combat the consequences of an ineffective organization structure. He may be called on to deal with individuals cracking under the strain of an impossible situation, and may well feel that he would be better engaged as a public health officer devising means of prevention than a physician attempting cure.

On the other hand, he is at present ill-equipped to advise on these matters. How many personnel managers, to take the simplest example, would be prepared to say what span of control in a particular hierarchical organization minimized the sum of the disadvantages of too little attention to immediate subordinates on one hand, and too many steps between bottom and top on the other? From his safe haven of aptitude tests of proved reliability and validity, and accurately pin-pointed learning curves, the personnel manager steps here into a largely uncharted world in which line managers can—and certainly will—argue with him.

Better use of human resources was discussed by a research psychologist and a personnel director. Dr. J. Hopkins, of the National Institute of Industrial Psychology, suggested that any task can be made to vary in at least three ways: duration, scope of action and responsibility. Any of these variables can be increased or reduced and job enlargement can result when they are increased in ways which succeed in strengthening the meaningfulness, although there might be considerable increase in duration, scope or responsibility. It should, however, be considered how far job enlargement might be psychologically desirable. Evidence of people's reactions to their jobs is still scanty and anecdotal. Attitude surveys and similar types of inquiry have shown that highly repetitive and subdivided tasks—the opposite of job-enlarged tasks—are apparently almost as congenial to some people as they are abhorrent to others. Whatever the variety of people's comments about work, they consistently reveal preoccupations with only a comparatively limited number of themes. Among the most frequent are the pace of the job, the security or insecurity engendered by it, its variety, its inherent creativeness, its difficulty and its sociability. These themes indicate a response to at least three identifiable aspects of work: the amount of constraint the task imposes, the 'completeness' which it allows one to experience, and the degree of personal involvement which it demands. The status or value of an enlarged job as against a more subdivided one should be viewed in relation to these aspects of work. T. G. P. Rogers, of I.B.M., United Kingdom, Ltd., is in no doubt that Britain has not fully developed its human resources, and quoted an example from I.B.M. in the United States to show what can be done. Much of that Company's work has changed from electro-mechanical to electronic engineering. Redundancy is anathema to the Company. It had to make electronics technicians out of machinists and assemblers. They had to be taught algebra, electrical and electronic theory, and computer theory as a prelude to their practical training and their subsequent employment on final test operations on computer manufacturing. This was done in such a way as to enable the American management to conclude that a substantial percentage of what are called semi-skilled operators are capable of this change, regardless of their age.

The important factors are—good selection in assessing mental ability, aptitude, and motivation, and thorough full-time class-room and workshop training. What is required in British industry is a new attitude in management towards operator training—skills should be taught and not bought; and also in many cases a new shop-floor attitude—more self-confidence and less rigidity of outlook.

The two final speakers were asked to look at industrial relations in the future. One, Mr. Frank Cousins, general secretary of the Transport and General Workers' Union, expressed the strong opinion that the basis of all industrial troubles is insecurity and that economic planning will not be possible until there is a new approach to industrial relations. Trade unions want to be consulted about more than the incidence of redundancy, and which men will go. They wish to talk about the basic reasons for redundancy and whether the workers have any place in determining the policies which cause or do not cause this redundancy to arise. There is, also, far too much tendency to accept that "if a firm or a trade union has bright ideas about the future of industrial relations, it sounds nice but you cannot do it unless you can persuade everybody to do it first; you cannot, in fact, wait for the slowest". Other views put forward by Cousins were that "if we regard industrial relations as a steady process of agreement on consultation through operating an agreed but flexible structure, we have still failed", and that "we will not resolve the problems if we think we have a common purpose. We have two different purposes. We have to see how we are going to serve them and how to bring the consequent results together at some stage. We do not start off from the basic level. This could be one of the most significant contributions to economic planning, if we first accept that principle".

The other, Sir Roy Harrod, Nuffield reader in international economics in the University of Oxford, discussed the relations of economic planning and incomes policy. For a number of years after the Second World War inflationary tendencies were certainly due to "too much money chasing too few goods", and the right way to correct this situation was by monetary and fiscal policies. In more recent times it has appeared, both in Britain and in the United States, that there might be a tendency to inflation, in the sense of rising prices, even in periods when it was perfectly clear that the monetary demand for goods and services was not excessive, as made evident, for example, by the economy being slack or depressed. It seemed inescapable that a rise in prices might occur simply because increases of wages, salaries, etc., were being granted in excess of any increase in national productivity and give rise to 'cost-push' inflation.

In the recent period people have become self-conscious about the fact that, in the past seven years, Britain has shown a low growth-rate. The same is also true of the United States. If Britain is to make a change in her monetary and fiscal policies and try to achieve the growth-rate of which the country is capable, this brings into the forefront the question of how to prevent inflation of the kind that is caused by a 'cost-push'. There is the possibility that a policy of full growth will tend to accelerate claims for higher pay and make employers, who, under a growth policy, will be enjoying good profits, readier to give them. Hence the idea of a National Incomes Commission.

The idea of a policy of planning for economic growth entails problems of formidable dimensions. Such a policy cannot be implemented without goodwill on the labour side, and to get labour goodwill it will be needful to show that there is some method to secure restraint on the side of distributions of dividend also. But within the field of wages itself there are vast problems. There is the question of relation of wage increases to productivity increases, the question of the 'wages drift', the question of differentials between grades and between occupations, the proper function of wage increases in relation to the mobility of labour as between rising and declining industries, the problem of leap-frogging, the question of how a trade union leader can relate his thoughts to a national policy without sacrificing, or seeming to sacrifice, the interests of the particular group of workers which he is appointed to look after.

All these interconnected questions have to be looked at in an impartial way without prejudice. Public opinion in certain quarters has been too much inclined to suppose that labour is always to blame when overall wage increases have been excessive, without appreciating the complexity of the problem. On its side, labour may not always understand the relation between excessive wage increases and inflation. The idea of looking at this complex of problems in a systematic and impartial way presents a great challenge.

In his presidential address to the conference, Mr. Gerald Moxon of United Glass, Ltd., reminded members that the Institute would be celebrating its jubilee in 1963. Its influence over many years in building up good industrial relations deserves to be much more widely known and it is to be hoped that suitable opportunities will present themselves in the coming year. It is so long since the Institute appealed for money to extend its activities that the Jubilee Appeal should meet with considerable response.

T. H. Hawkins

BONE MARROW THERAPY AND CHEMICAL PROTECTION IN IRRADIATED PRIMATES

During August 15–18 an international symposium on "Bone Marrow Therapy and Chemical Protection in Irradiated Primates" was held in Rijswijk, the Netherlands. The symposium was sponsored by the Organization for Health Research of the Central Organization for Applied Scientific Research in the Netherlands (T.N.O.), and the Radiobiological Institute T.N.O. acted as host for the meetings. There were 32 participants from France, the Netherlands, the United Kingdom and the United States, of whom 22 presented papers. The main object of the symposium was to exchange ideas as to the causes of difficulties in the treatment of irradiated primates, including human patients, and to discuss future research plans to overcome these difficulties.

In the session on "Bone Marrow Transplantation in Monkeys", C. Ambrus (Roswell Park Memorial Institute, Buffalo) presented data on homologous and autologous bone marrow transplantation in rhesus monkeys. Autologous transplantation gave better survival than homologous, but a high percentage of the homologous-treated animals survived for as long as 24 months with evidence of secondary disease in only one animal. The data showed that there was a marked tendency toward reversal of the chimæric state in the homologous-treated monkeys.

R. J. Young (Radiobiological Laboratory, Austin, Texas) reported the results of homologous and autologous transplantation in twenty rhesus monkeys. Autologous transplantation afforded good survival, but there were no long-term homologous survivors. The data showed evidence of secondary disease in homologous animals in which the take of the graft was ascertained by red cell antigens.

The data presented by Mrs. F. Newsome (University of Tennessee Medical Units, Memphis) showed evidence that homologous marrow after 550 r was more effective 48 h after irradiation than at 30 h. She reported on heterologous transplants using cynomolgus donors and rhesus recipients with the electrophoretic patterns of hæmoglobin serving as an indication of the take. She concluded that the grafts took but were later rejected. The same results were seen in cynomolgus monkeys treated with homologous marrow. Autologous transplantation in 19 rhesus monkeys was reported by R. Schofield (Paterson Research Laboratories, Christie Hospital, Manchester) in which six animals survived for more than 30 days post irradiation. A large number of deaths was attributed to bacteræmia.

L. M. van Putten (Radiobiological Institute T.N.O., Rijswijk) reported that several methods used in mice to prevent or treat secondary disease apparently do not work in monkeys. Preliminary results, however, indicate that the use of fœtal liver shows some promise in this direction. A detailed report of the pathology of secondary disease in primates was presented by M. J. de Vries (Radiobiological Institute T.N.O., Rijswijk), in which he showed striking similarities between this process in monkeys and humans and pointed out their differences with reference to mice. The prominence of secondary disease in the monkeys treated by R. J. Young *et al.* and those treated by the Rijswijk group was in sharp contrast to the absence of this complication in Ambrus's cases and in cases reported previously by B. G. Crouch (U.S. Naval Radiological Defense Laboratory, San Francisco) and R. R. Overman (University of Tennessee Medical Units, Memphis) and this discrepancy gave rise to much discussion. It was also concluded that much more insight was needed into the reactions of primates on homologous bone marrow transplantation following midlethal and sublethal doses of radiation in view of the adverse results obtained by Mrs. F. Newsome.

There were two papers in a session on the "Immunological Activity of the Primate Fœtus". H. E. M. Kay (Royal Marsden Hospital, London) reviewed the knowledge of the development of the lymphatic tissues in the human embryo and presented the results of the administration of fœtal liver cells in cases of bone marrow aplasia. He also reported on preliminary results with fœtus to fœtus transplants in cases of Rh incompatibility with little evidence of a proliferation of the grafted cells. R. Bangham (National Institute for Medical Research, Mill Hill, London) described his methods of immunizing and sampling monkey fœtuses at various ages. He obtained evidence of immunological reactivity in embryos as early as 9 weeks gestation.

In the session on Monkey Colony Management, D. B. Gisler (Wright-Patterson AFB, Dayton, Ohio) presented details of a method for determining the age of monkeys from roentgen graphs by measuring skeletal growth and epiphyseal ossification. A. J. Riopelle (Yerkes Laboratory, Orange Park, Florida) discussed the breeding and raising of chimpanzees for biological research with particular reference to radiation studies. Problems of the sanitation of monkeys brought from their natural habitat into the laboratory situation were reviewed by D. van der Waay (Radiobiological Institute T.N.O., Rijswijk). He related experiences with rhesus, cynomolgus, pig-tail and African green monkeys and emphasized the problems connected with parasitism and bacterial infections.

N. Gengozian (Oak Ridge Institute of Nuclear Studies, Tennessee) described the care and handling of the pigmy marmoset for laboratory studies. In addition, he presented preliminary data on the LD_{50} for this species and data on various peripheral blood parameters following irradiation, which suggested that the marmoset is relatively more radiosensitive than other monkeys studied so far. A systemic dermatosis of uncertain ætiology in the rhesus monkey was described by M. J. de Vries (Radiobiological Institute T.N.O., Rijswijk). The disease has proved to be fatal in a number of cases and is postulated to be due to an interference with vitamin A utilization. Histological examination of tissues showed striking similarity to those seen in X-disease in cattle.

In the session on "Human Applications of Bone Marrow Transplantation", N. B. Kurnick (University of California, Veterans Administration Hospital, Long Beach) advocated the storage of bone marrow for all patients undergoing extensive radiotherapy. Re-infusion after the occurrence of aplasia is only occasionally needed, but may in those cases be of great benefit. Evidence was brought forward to show that in this respect man differs markedly from the mouse, since in this animal subtotal irradiation rarely causes dangerous aplasia. J. G. Humble (Westminster Hospital, London) gave an account of the application of autologous bone marrow suspensions in large volume radiotherapy. This improves the safety of the procedure and once the other risks of large volume therapy (radiation pneumonitis) have been identified, the technique opens new therapeutic possibilities. E. Loeb (Wadley Research Institute, Dallas) discussed the use of stored autologous bone marrow after radioisotopes in high doses in the palliative treatment of malignant tumours and attempts at homologous bone marrow treatment after total body irradiation for leukæmia. The techniques of storage were extensively discussed. J. Ambrus (Roswell Park Memorial Institute, Buffalo) similarly advocated the storage of hæmopoietic cells for patients undergoing chemotherapy or irradiation combined with chemotherapy and discussed in addition a number of experimental studies. G. Mathé (Hôpital Saint-Louis, Paris) summarized his experience with homologous bone marrow therapy in the treatment of radiation accidents and after therapeutic irradiation of patients with leukæmia. From his series of clinical data, man appears to be more radiosensitive than most experimental animals with the LD_{50} at approximately 400 r.

In the session on "Chemical Protection of Primates", J. R. Newsome (University of Tennessee Medical Units, Memphis) discussed the results of combined treatment with two different chemicals. The use of both aminoethylisothiuronum (AET) and para-aminopropiophenone (PAPP) had a markedly greater dose-reducing effect than did either compound alone. G. S. Melville (School of Aerospace Medicine, Brooks AFB, San Antonio) presented similar data combining AET with cysteine in rhesus monkeys. He also presented evidence to show that 'Nembutal' enhanced the dose-reducing capacity of these compounds. AET and cysteine were also combined in the protection of monkeys against 800 r by L. van Lancker (University of Wisconsin, Madison). He concluded that an effective X-ray dose reduction was obtained with these compounds and further that marked cellular regeneration of spleen and bone marrow were evident in protected animals by 30 days following irradiation.

The *Proceedings* of the symposium, including the discussions, became available on November 1 and can be obtained from the Radiobiological Institute T.N.O., 151 Lange Kleiweg, Rijswijk (ZH), Netherlands, and from Dr. R. R. Overman, University of Tennessee Medical Units, Memphis, Tennessee, U.S.A., at the price of 4 U.S. dollars.

D. W. VAN BEKKUM

MODIFICATION OF THE WEATHER

> "He who controls the weather controls the world."
>
> LEONARDO DA VINCI

SINCE the day when primitive man first became aware of, and was awed by, the forces of Nature he has sought to control them. Although throughout the centuries he has been successful to some extent in moulding his environment and harnessing the forces of Nature to his advantage, his success in controlling those natural phenomena which have marked the behaviour of the Earth, oceans and sky throughout time has been very limited, if not negligible.

With the rapid advances which have been made in the atmospheric sciences during the past two decades, it is not surprising that meteorologists have looked towards weather and climate control as a serious goal capable of attainment. Besides this desire is the natural wish of mankind to make his environment more comfortable and less hazardous. This is particularly true for the inhabitants of those parts of the world where the weather can cause loss of life or destruction of property or economic ruin, either by sudden catastrophic storms, or by slow, but just as disastrous, occurrences such as drought or floods which bring about crop failure or destruction and famine; and behind all this there are, of course, the military and political dreams of controlling the climate on a large scale. These thoughts may have existed for a long time; but it is only in the past fifteen years that any real attempt has been made to answer them, and only in the past three or four years has such an attempt been transformed into a major scientific programme. This programme is world wide. Within the global programme there exists a United States programme in weather modification, defined by natural needs for weather control. The responsibility for the national programme is held by the National Science Foundation, which has been directed to initiate and support a programme of study, research and evaluation in this field. The Foundation is advised by an Advisory Panel for Weather Modification*.

A great deal of the work which is being carried out under the heading of weather modification is concerned with basic studies in cloud physics. The work of Prof. B. J. Mason in Great Britain (*Nature*, 195, 647; 1962) is an example of the way in which the problem is being attacked. Fundamental laboratory research into the properties of condensation and freezing nuclei and cloud droplets and the mechanism of precipitation processes is essential before experiments in the atmosphere to stimulate precipitation artificially can be expected to give successful results as judged by accepted statistical evaluation tests. It is interesting to note that in the kaleidoscopic pattern of jargon the former much-used phrase of 'artificial precipitation' appears to have been replaced by the wider and more sober one of 'weather modification'. However, the more spectacular possibilities of rain-making seem, in part, to lie hidden behind the broad front of the programme of weather modification.

Much work on cloud seeding has been carried out not only in the United States but also in many other countries. Argentina, Australia, Canada, France, Israel, Italy, Japan, Mexico, South Africa and the U.S.S.R., among others, have all engaged in such experiments. But the conclusion cannot be escaped that success has been very limited indeed. All the results confirm that, although rain can at times be stimulated artificially, much more needs to be known about all the variables before cloud seeding can be carried out with predictable results.

Artificial precipitation is, of course, not the only form of weather modification. Cloud seeding has been used in an effort to evaluate the possible suppression of hail. Hail samples have been gathered from areas within and outside a seeded district to determine the amount of silver iodide, the seeding agent present, and to examine the effect the agent may have had in suppressing hail. Present theory is quoted as indicating that hail can be suppressed by cloud seeding. However, statistically the results of hail suppression projects are contradictory and confusing. It is certain that the physics of hail formation must be better understood before much further progress can be expected. In Switzerland, a Federal Commission for studying formation and prevention of hail was established in 1950 and at present operates three laboratories. A number of field experiments have been carried out. The experimental evidence shows that seeding with silver iodide has no extensive effect in terms of an overall suppression of hail. At the same time, it is not possible to determine from the available data whether the seeding has altered the extent and intensity of hail-fall. Generally speaking, the number of days on which hail falls is too small to justify a thorough statistical evaluation of the results according to the areas over which hail of varying intensities falls.

Other aspects of weather modification have also been considered. Some investigations have been made at New York University on the feasibility of the artificial modification of tropical storms; but even this involves the possible effects of cloud seeding. Wider objectives, such as the effect of modifying the air/sea boundary and the internal energy transformations, or altering the physical composition of the storm will also be studied. A U.S. Weather Bureau project will use standard cloud-seeding methods to release latent heat and so try to create asymmetries in the storm.

Another project is concerned with the absorptive power of a pure carbon cloud. It was found that for 3×10^5 particles of carbon per c.c. and a zenith distance of the Sun of 60°, 32 per cent of the Sun's radiation is absorbed in a cloud 100 m thick. Such a cloud would require 30 kg of carbon per km^2. The effects in the atmosphere are complex and depend on many variables such as the water vapour content above and below the cloud, the elevation of the Sun and other factors.

In Sweden plans were laid, but not carried out, to spread radiation-absorbing dust on snow-fields to accelerate melting in late spring. Experiments were conducted there to spread fatty alcohols on snow-fields in order to diminish their evaporation. Attempts have been made in several countries to reduce the natural evaporation from lakes and reservoirs by spreading and maintaining a suitable chemical film over the water surface.

---

* National Science Foundation. Weather Modification—Third Annual Report for Fiscal Year ended June 30, 1961. Pp. vi+78. (Washington, D.C.: Government Printing Office, 1962.) 30 cents.

The third annual report on Weather Modification of the U.S. National Science Foundation shows that these problems are much in mind at the present time. It seems, however, from the existing results that progress will be slow. The next few years will see a consolidation of facts and basic ideas on the mechanism of the physical meteorological and climatological processes which govern the behaviour of our atmosphere, rather than any spectacular advance in man's attempts to modify the weather to any marked degree. Small local phenomena may indeed be brought into being, dissipated or modified. For the time being, meteorologists should not allow their imagination to run wild with the hope of changing things effectively on a wide scale. A. H. Gordon

THE LOW TEMPERATURE RESEARCH STATION, CAMBRIDGE

THE first International Congress of Food Science and Technology held in London during September directed attention to the ever-increasing interest in the nature of food materials and modern techniques of food production. The recent publication of the annual report for 1961[*] of the Low Temperature Research Station, Cambridge, is therefore timely and will, no doubt, be received with particular interest by those who visited the Research Station during the week of the Congress and attended sessions which dealt with papers on the progress of its activities.

An account of some of these activities, set against a background of the present state of each subject, forms the essential content of the report. Together with its accompanying brochure, *The Low Temperature Research Station, Cambridge*[†], the wide range of interests of the Station is well presented. A particularly noteworthy aspect is the substantial contribution to modern food handling and processing practices emerging from the results of its research work.

The preface describes the function of the Station as research into the principles of the preservation of foods. As would therefore be expected, considerable attention is directed to the newer methods of food preservation, such as radiation sterilization and freeze dehydration.

"Accelerated Freeze Drying of Meat" is the title of the second report, dealing with ultimate pH on the quality of freeze-dried meat. The results obtained should be of particular interest to those concerned with potential applications of accelerated freeze drying to the preservation of meat. This report is preceded by a detailed survey entitled "Anatomy and Physiology in Meat Research". Factors influencing quality are summarized under the headings of "Constitution" and "Condition".

The data presented on immersion freezing (air and liquid) of poultry are of immediate practical interest. A reassessment of heat extracted in freezing chicken should be found useful in equipment design. It will be of advantage to have further data with the publication of full experimental details.

Much of the pioneer work on liquid whole egg pasteurization was carried out by the late Dr. J. Brooks. This has now led to the successful development of the amylase test. The effectiveness of the test can be judged from the last paragraph of this account: "The results of a number of technical trials recently carried out indicated that the amylase test could be used to detect an error of 0·5° F (1° C) in the setting of the temperature control instrument of a commercial pasteurizer; serial results could be made available 1 h after taking the first sample. The amylase test has also been applied to samples of pasteurized whole egg of widely different origin and has correctly indicated the severity of the heating treatments used".

Under the title "Twelve Years of Radiation Preservation Research" progress in another branch of food research is briefly reviewed. Much interest has been shown to exist in this new method of food preservation and some of the results reported here show considerable promise. The study of radiation pasteurization of frozen whole egg carried out in collaboration with the Isotope Research Division of the Atomic Energy Research Establishment was reported at the Congress. This may prove to be of commercial value. The effects of irradiation of other foods, including pork sausage and fish, are also mentioned. The latter application deals with white fish species which have been found to respond well to treatment and, at the maximum tolerable dose, considerably extended the storage life at 0° C and 4° C.

The successful application of all methods of food preservation so far discussed depends on adequate packaging. Gas sampling in vacuum packs forms the main topic in the report entitled "Physical Problems in Packaging of Foodstuffs". Gas analysis is of great importance in assessing this type of package performance and a systematic study of the subject should be welcome.

The technique of gas chromatography has also been applied to the analysis of flavour. Work recently started on the flavour of meat and poultry and preliminary results indicate that here, too, the breakdown products of amino-acids can make a notable contribution to flavour. The study of flavour during irradiation should yield further results of considerable interest.

Two other reports, dealing with phospholipids and the classification of micro-organisms, complete a review of some of the activities during 1961.

The report contains a comprehensive list of recent publications. In addition, references to the literature are quoted at the end of most of the reports presented. A photograph depicting one of the rooms at the Meat Research Laboratory, Cherry Hinton, is included.

Other photographs appear in the accompanying brochure together with selected excerpts from the annual reports 1959–62. This booklet also includes an account of the work and achievements of Sir William B. Hardy, founder of the Low Temperature Research Station. R. A. P. Wertheim

THE NATIONAL RESEARCH COUNCIL OF CANADA

A NEW format has been adopted for the forty-fifth annual report of the National Research Council of Canada, covering the year 1961–62, but the report is on the usual lines and includes the annual reports of the Medical Research Council and of Canadian Patents and Development, Ltd.[*]. During the year, 8·7 million dollars went in support of pure research in the universities, including 975 grants and 675 scholarships and fellowships, as well as a further 3·3 million dollars through the Medical Research Council. The scientific research staff now numbers 733 (including 163 postdoctorate fellows) with 997 technical personnel and 890 general service and administrative staff. A notable development of the year was the Government's decision to give financial assistance to research and development in Canadian industry, and in 1962–63 a special committee of the Council will make awards totalling 1 million dollars in support of long-term applied research in industry. Besides this, the Council is already responsible for wide programmes of objective basic research, as well as undertaking applied research under contract and operating technical information and documentary services. Support for university science has increasep from 3·6 million dollars in 1957 to 14·4 million dollars in 1962.

Brief summaries are included of the work done in the Division of Applied Biology in the Atlantic Regional Laboratory, Halifax, the Prairie Regional Laboratory, Saskatoon, the Divisions of Applied Chemistry, Pure Chemistry, Applied Physics, Pure Physics, Building Research and Mechanical Engineering, the National Aeronautical Establishment and the Radio and Electrical Engineering Division. Under the Medical Research Council, 96 programmes directed by senior scientists were supported on a three-year basis and 224 on a renewable annual basis, while 64 fellowships, totalling 236,642 dollars were held. Of cases coming to the Canadian Patents and Development, Ltd., during the year, 39 per cent originated in the laboratories of the National Research Council, 47 per cent from other Government agencies and departments and 14 per cent from universities and provincial research institutions. Besides 107 patent applications filed, 150 patents were issued in 13 countries.

PRESERVATION OF WILD LIFE AND ZOOS

IN her book *Orang Utan*[1] Mrs. Harrisson describes rearing baby orangs confiscated from poachers in Sarawak and taking them to European zoos. Having learnt something of their needs, she considers the possibility of training them to return to their natural jungle habitat. In a later paper, entitled "First Response to Freedom of Young Orang-Utans at Bako National Park, Sarawak"[2], she describes the first stages of an experiment in rehabilitation.

In the first three years orang babies are nearly as helpless as human babies; they need a mother-figure as much, and they will endlessly adapt their behaviour to fit the environment the 'parent' provides. The problem is to bring up a baby to a stage when it can cope alone with its jungle environment, without distorting its behaviour so much that it is unable to break free of human society when the time comes. Up to the time of writing the paper the problem had not been solved, and if the experiment is to be successful newly independent females must not only be self-sufficient, but so shy of their former nurses that they will not bring their own babies within easy shot of poachers.

An earlier paper of Mrs. Harrisson[3] and Dr. T. Harrisson's addenda to the book show how vital it is that these experiments should succeed. Simple arithmetic shows that if the present situation remains unchanged the orang-utan has about ten years left. An orang should live thirty or forty years: in zoos their average life is four years, and breeding in captivity is negligible, so to maintain the present world zoo population 60 replacements are required each year. To exhibit a baby costs the life of its mother, and the mother of another baby who will die in transit. Thus in ten years 2,400 animals are lost from a population which stands at present between two and five thousand and is probably already overweighted with adult males, which do not interest collectors.

It is highly questionable whether the import of orangs, or any other threatened species, should be allowed into civilized countries. There is no justification on scientific grounds because it is now cheaper and easier to transport the biologist to the ape than vice versa. The real irony of the situation is that these orangs acquired at so much cost are then kept in such a way as to make them useless as entertainment or for research. Probably the main function of this book will be to help to teach a basically kind-hearted but uncomprehending public that the sad-eyed hulks of apes in zoos bear no more resemblance to mentally healthy creatures than would a human being maintained in the same way. The clear account of the needs of the baby orang should prevent the demands on the pet market (and ultimately the poachers) which books of this type are apt to produce. (Compare, for example, the assortment of unsuitable felids that were bought as a result of *Born Free*). Orangs are said to be more stupid than chimpanzees, but this impression has arisen because they are expected to behave like the mainly terrestrial and imitative African apes. The orang is arboreal and must have trees to climb; it is an explorer rather than an imitator. Its requirements sound like a zoo director's nightmare. How do you provide thirty years' worth of exploration?—yet they should be considered as necessities, in the same way that a zoo does not acquire a giant panda until it has assured a supply of bamboo.

The expense, in space, materials, and time which is needed to provide adequate environments is one which very few zoos are willing to face. Before real improvements can be made it will be necessary for zoos to reconsider their whole function, because their present way of thinking belongs to the past century. Then it was valuable to collect together large numbers of closely related animals, a single specimen of each perhaps, since zoology was mainly a form of taxonomy: but completeness of the collection is still a criterion of excellence, as in a collection of postage stamps. Then the public could be educated and entertained just by seeing legendary foreign animals in the flesh: now that we have superb wildlife films people are surely becoming more sophisticated about animals, and realizing that cage-stupid isolated specimens are little better than stuffed animals, and that begging for food is the least entertaining behaviour that animals have in their repertoire.

The time has now come when for both entertainment and scientific value it would be more profitable for a zoo to specialize and concentrate on one species from any group—for the lay public, and indeed for most zoologists, the difference between, say, a chacma and an olive baboon is of little moment—but to use the space and resources saved to present that species as a flourishing breeding colony. In this way it might become possible to pay more than lip-service to the idea of breeding and maintaining vanishing species in captivity, which is the only excuse for having such animals as the orang in captivity at all. Co-operation between zoos could prevent overlap, so that each could become famous for its specialities and worth using the facility of modern transport to visit. Let us hope that this book will prod the imagination as well as the consciences of zoo directors, and help to make people dissatisfied with some of their present offerings—with the rare exception, the 'good' British zoos are not even up to the standards of the American and European.

For the orang itself, the most urgent need is for reserves in south-east Asia. These must be protected from poachers, of course; they must be large enough, because the population density of orangs seems to be about one per square mile; and the size of the area must be estimated in terms of useful orang habitat, which is forest at least eighty years old. A first park has been established in North Borneo, but on Mrs. Harrisson's estimate[4] the present boundaries include space for only fifteen adults. There is a conflict between the interests of the orang and those of timber merchants and traditional hunting rights; as usual, conservation is a political, not biological, problem. If nothing is done within the next few years, the conflict will cease to exist.

I found the arrangement of the book too chatty; orangs are interesting enough without padding (for example, a digression about turtle eggs) and I felt to be piecing together relevant information with difficulty. If, as must be the intention, this treatment attracts a wider audience, it is a worthwhile sacrifice. The photographs are delightful; I suspect that one of the orangs facing page 176 is a chimpanzee.

BOTANICAL EXPEDITION TO THE LIMESTONE AREAS OF ULU KELANTAN, MALAYA

By HSUAN KENG
University of Singapore

UNDER the sponsorship of the Unesco Science Co-operation Office in Djakarta, a botanical expedition to Ulu Kelantan, Malaya, was undertaken during July 24–August 17.

At a conference several years ago, Dr. E. J. H. Corner, former assistant director of the Singapore Botanic Gardens, directed attention to the fact that the present knowledge about the peculiar limestone flora in South-east Asia is very inadequate. This flora extends from south Thailand through Malaya to Borneo and Java.

The limestone hills in Malaya are widely distributed in the northern States. According to a recent report by Mr. J. R. Paton[1], they are concentrated in Ulu Kelantan. Furthermore, the limestone hills are less explored and less disturbed there. For these reasons, it was generally agreed that Ulu Kelantan was the most suitable place for the expedition.

Participants of this expedition included staff members from the Singapore Botanic Gardens, the Forest Research Institute of Malaya and the graduate students of the University of Singapore. The foreign participants came from neighbouring countries: Thailand, Indonesia, Hong Kong, and the Phillipines. Altogether the party consisted of sixteen members. The exploration was called a 'training expedition' because the participants were expected to gain knowledge and experience of botanical field work. Actually this was the third one of its kind sponsored by Unesco, the first being held in Java in 1960, the second in Sarawak in 1961.

The party spent three weeks in the field. By the end of this time the party had collected 691 (many with 4–6 duplicates) kinds of dried herbarium specimens and more than 200 kinds of living plants. The dried herbarium specimens, more than 3,200 sheets, are kept in the herbarium of the Singapore Botanical Gardens for future distribution to the leading herbaria of the World; the living plants, including a great variety of orchids and other plants, are being kept in the gardens for multiplication.

The only literature available about the Malayan Limestone flora is the paper written by Mr. M. R. Henderson[2]. In that paper, Mr. Henderson enumerated 745 species of seed plants which were found on the limestone hills throughout Malaya. Among these 745 species only 195, or approximately one-fourth, of them were confined to the limestone hills; the rest was found both on limestone and non-limestone hills.

From a preliminary examination of the present collections several interesting points emerge:

(1) Mr. Henderson listed 49 families which had not been found on Malayan limestone hills. However, among our collections from Ulu Kelantan, specimens belonging to Ranunculaceae, Caprifoliaceae, Hamamelidaceae and Bignoniaceae were found. These five were among Henderson's 49. Thus all of them are new records to the Malayan limestone flora. Incidentally, the first two families, Ranunculaceae and Caprifoliaceae, are represented in the collections by only single specimens of *Naravelia dasyoneura* Korth. and *Viburnum sambucinum* Bl. respectively. This means that they are extremely rare.

(2) Ferns and fern allies were excluded from Mr. Henderson's list. During this expedition, more than 90 species of ferns and fern allies were collected.

(3) Dipterocarpaceae, which are so characteristic of the tropical rain forests, are poorly developed in the forests on limestone hills[3]. According to Mr. Henderson's list, only three species, each representing a genus—*Vatica*, *Hopea* and *Pentacme*, were recorded. At the end of this expedition, 3 species of *Shorea* and 1 species of *Parashorea* were added to our knowledge of the limestone dipterocarp flora.

(4) Orchids are abundant, especially near the tops of limestone hills. About 100 species of orchids were collected during this expedition. A great variety of living specimens of orchids, plus ferns, begonias, aroids, gingers and others of ornamental value, were brought back. Most of them are growing well in the Singapore Botanic Gardens to-day. In this connexion, perhaps it is worth while to mention the fact that a large number of the beautiful herbaceous plants from the limestone hills have proved to be valuable garden plants in lowland Malaya. According to Mr. Tem Smitinand, a participant from Thailand, who identified all the orchid specimens, nearly one-third of orchids collected are new records of the Malayan limestone flora, and at least two of them are new species.

A list of the plant names of his collection will be compiled in due course.

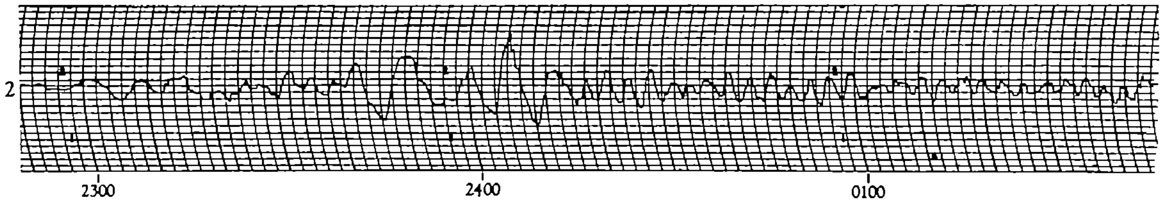
SUB-ACOUSTIC WAVES FROM RECENT NUCLEAR EXPLOSIONS

By PROF. R. V. JONES, C.B., C.B.E., and S. T. FORBES
Department of Natural Philosophy, University of Aberdeen

BETWEEN 2000 and 2100 G.M.T. on July 9, 1962, an unusual train of microbarographic waves was recorded in the Aberdeen area. The atmospheric pressure was otherwise uncommonly steady that evening; the normal degree of 'noise' in this area would have masked the wave-train, which had a peak amplitude of about 25 microbars (μb). Fig. 1 shows the appearance of the train, recorded on a microbarograph set to respond to periods between 10 sec and 5 min. The time of onset of the train is difficult to decide exactly; there is an indication of waves of period about 5 min and 8 μb amplitude arriving about 2000 G.M.T., followed at about 2020 G.M.T. by waves of period about 2·5 min and up to 25 μb amplitude. The tail of the train was lost in the noise by 2200 G.M.T.

We have previously seen wave-trains of this type only after violent explosions in the atmosphere; but then the initial longer period (4–6 min) waves have usually been of greater amplitude than the following 2–3 min-waves (see, for example, Jones[1]). Tentatively, we may examine the possibility that the July 9 wave-train originated in a nuclear explosion, perhaps with abnormal characteristics such as to



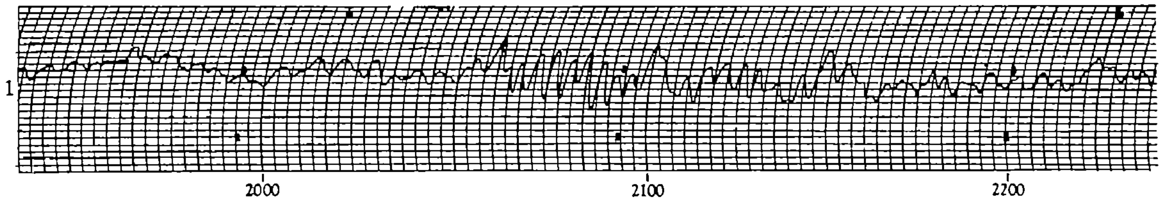


Fig. 1. Microbarograph record of July 9, 1962, at Aberdeen, showing wave-train appearing to have originated from 'Rainbow' explosion near Johnston Island at 0900 G.M.T. the same day. Numbered ordinates at 2000, 2100, 2200 G.M.T. Pressure scale, 1 division ~ 3 μb, for waves of period between 10 sec and 5 min

Fig. 2. Microbarograph record obtained on August 6 and 7, 1962, near Aberdeen of sub-acoustic wave-train from explosion near Novaya Zemlya on August 5, 1962. Wave-train was passing over Aberdeen for second time, after encircling Earth. Numbered ordinates at 2300 and 2400 G.M.T., August 6, 1962, and 0100 G.M.T., August 7, 1962. Pressure scale, one division ~ 15·5 μb, for waves of period between 15 sec and 7·5 min

moderate the initial violence of the disturbance. Earlier that day (0900 G.M.T.) the 'Rainbow' bomb[2] had been exploded at some hundreds of kilometres above sea-level near Johnston Island. The travel times for sub-acoustic waves arising from the explosion would give, on previous experience[3], expected times of arrival in Aberdeen of between 1912 and 1945 G.M.T. for waves of 5-min period, and between 1930 and 2020 G.M.T. for 2·5-min period. The times at which the waves were observed at Aberdeen are at the ends of these brackets, but the coincidence suggests the conclusion that the wave-train originated from the 'Rainbow' explosion.

It would thus appear that substantial energy was communicated from the explosion (stated to be in the megaton range) to the lower atmosphere, despite the fact that the explosion was nominally 'outside' the atmosphere. Presumably about half the explosive energy was radiated downwards, and the subsequent atmospheric disturbance was due to the partial absorption of this radiation. The comparative lateness of the wave-train may have been due in part to some feature of the process by which the pressure waves were developed.

The Russian explosion of August 5, 1962, gave rise, as did that of October 31, 1961 (ref. 1), to waves which could be traced on more than one circuit of Earth; the explosion is thought to have been of about 30 megaton TNT equivalent.

Times of passage at Aberdeen were as follows:

	G.M.T.		Peak amplitude
Direct wave	1148	5.8.62	> 500 μb
Antipodal wave	1734	6.8.62	150 μb
Direct wave (second transit)	2340	6.8.62	200 μb
Antipodal wave (second transit)	0542	8.8.62	80 μb
Direct wave (third transit)	1200	8.8.62	80 μb

These data give times of 35h 52m and 36h 20m for the completed direct circuits and 36h 08m for the completed antipodal circuit. These times are more uniform than those recorded here for the 1961 explosion.

Fig. 2 shows the record of the second passage of the direct wave, which had an unusually well-developed train lasting more than 2 h; there appears to have been strong dispersion. The record was obtained at the Loch of Skene, about seven miles west of Aberdeen, and our thanks are due to Lord Cowdray for allowing us the use of the Loch.

LAKE VANDA: AN ANTARCTIC LAKE

By Dr. A. T. WILSON and Dr. H. W. WELLMAN
Victoria University of Wellington, New Zealand

Lake Vanda as a Solar Energy Trap

LAKE VANDA is shown to be a natural example of the trapping and storing of solar energy by a salt water density gradient. The bottom of this Lake (218 ft.) is maintained at 25° C despite a mean annual air temperature of about −20° C, the solar heating being limited to the short antarctic summer.

The Lake (77° 35′ S., 161° 39′ E.) is permanently covered with about 12 ft. of ice and is 5 miles long and 1 mile wide. It occupies a depression in the lowest part of the Wright Dry Valley, Victoria Land, Antarctica. In the summer of 1960–61 an American biological party discovered that its bottom waters were warm and highly saline[1].

We examined the physics and chemistry of the Lake and the geology of the surrounding area during the first half of December 1961. This communication deals with the heat balance of the Lake.

Twelve holes were drilled at 1,000-ft. intervals along two lines, one along the length of the Lake and the other across its widest part. Water temperatures were measured to ± 0·05° C at 5-ft. intervals, using a copper–constantan thermocouple and a potentiometer. The thermocouple was checked against a reversing thermometer of the type used in oceanography. Density and chemical composition were measured at 5-ft. intervals through one hole in the central part of the Lake. The lower region of the Lake below 160 ft. is strongly density-stratified saline water which we consider to be non-convective. The *in situ* density increases from 1·007 g/cm³ at 160 ft. to 1·100 g/cm³ at 215 ft.

The temperature gradient in the soft mud at the Lake bottom was measured near the centre of the Lake by driving in a geothermal gradient probe. This probe consisted of 76 copper–constantan couples connected in series and mounted on a wooden rod with their junctions 25 cm apart. The probe was calibrated by placing it at the 170-ft. level in the Lake where the gradient was known from the thermal profile measurements. This calibration agreed with that calculated theoretically to within 10 per cent. 2 ft. below the bottom of the Lake the temperature was found to be decreasing downward with a gradient of 0·04° C per foot. Heat is thus being conducted downwards from the Lake. Assuming the thermal conductivity of the mud salt water mixture at the bottom of the Lake to be similar to that of water, the annual flow of heat would be about 50 cal/cm²/yr.

Bolometer measurements of the solar energy flux were made through five holes under a variety of cloud conditions and at depths up to 50 ft. below water-level.

The heat balance of the Lake presents some interesting problems. The temperature gradient at the 165-ft. level is 0·37° C/ft. This means that the non-convective lower part of the Lake is losing heat at 550 cal/cm²/yr. by conduction upwards. To this must be added the 50 cal/cm²/yr. that is being lost downward by conduction through the bottom of the Lake.

There are five possible heat sources: (1) biological activity within or at the base of the Lake; (2) chemical heating; (3) hot springs in the bottom of the Lake;

Table 1

Temperature versus depth profiles for lower part of Lake Vanda (°C)

* Positions of holes 1, 2, 3, 4 are on an east–west line at 1,000-ft. intervals. 2 N and 2 S are at positions 1,000 ft. north and 1,000 ft. south respectively of position 2.

(4) abnormally high geothermal gradient under the Lake ; (5) radiant energy from the Sun penetrating into the Lake and being absorbed.

According to Zobell *et al.*[2], biological activity would not produce more than an extremely small part of the heat required even under the most favourable conditions.

Coring of the bottom yielded no solid soluble salts. The bottom waters of the Lake contain in solution calcium chloride with smaller amounts of sodium and potassium chlorides. Even if these salts did occur on the bottom of the Lake, consideration of their heats of solution[3] rules out any appreciable heating from this source. There is no evidence for any other chemical reactions that are producing appreciable heat.

There is no geological evidence for hot springs in the area surrounding the Lake. The temperature-gradient is positive at all depths in all profiles measured. In the lower half of the Lake the temperature versus depth profile is remarkably similar (± 0·1° C) over an area at least 3,000 ft. by 2,000 ft. (Table 1), whereas hot-spring areas are characteristically non-uniform in lakes.

The possibility of a high geothermal gradient is ruled out, since the temperature-gradient probe showed that heat is being conducted out through the bottom of the Lake. Other evidence is that the temperature gradient decreases from 160 ft. downward. This is not a salinity effect since the thermal conductivity of water decreases as the salt concentration increases[4], and implies that the flow of heat increases as one goes upwards.

Thus we are left with radiant energy from the Sun as the only possible source of heat. No data are available on the total annual radiant solar energy flux at Lake Vanda, but it is known[5] that the solar energy flux at Scott Base, 80 miles due east of Lake Vanda, is 91,000 cal/cm²/yr. The fraction of the incident solar energy which penetrates the 12 ft. of ice was determined with a bolometer. With a cloudless sky, 5 per cent, and with a cloudy sky, 8 per cent of the radiant energy flux enters the water below the ice. Measurements in the upper 50 ft. of the Lake showed that 45 ft. of water reduced this energy flux to a half. By adopting a 6 per cent value at the bottom of the ice and assuming that the water maintains the same attenuation value, the quantity of energy reaching the 165 ft.-level would be 550 cal/cm²/yr., which is in reasonable agreement with the 600 cal/cm²/yr. calculated above as the loss of heat from the Lake water below 165 ft.

As additional evidence of a solar heating mechanism, the temperature gradient below 160 ft. has been calculated using the above data and is compared with the observed data in Table 2.

Table 2

Depth below water-level (ft.)	Colour of water	Per cent of incident energy	Total energy flux (cal/cm²/yr.)	Calculated temperature gradient (°C/ft.)	Measured temperature gradient (°C/ft.)
165	colourless	0·6	550	0·33	0·37
170	,,	0·55	500	0·30	0·35
175	,,	0·51	465	0·28	0·33
180	,,	0·47	430	0·25	0·30
185	,,	0·44	400	0·23	0·27
190	,,	0·41	375	0·22	0·26
195	brown	0·38	350	0·20	0·20
200	,,	0·35	320	0·18	0·14
205	,,	0·32	290	0·16	0·10

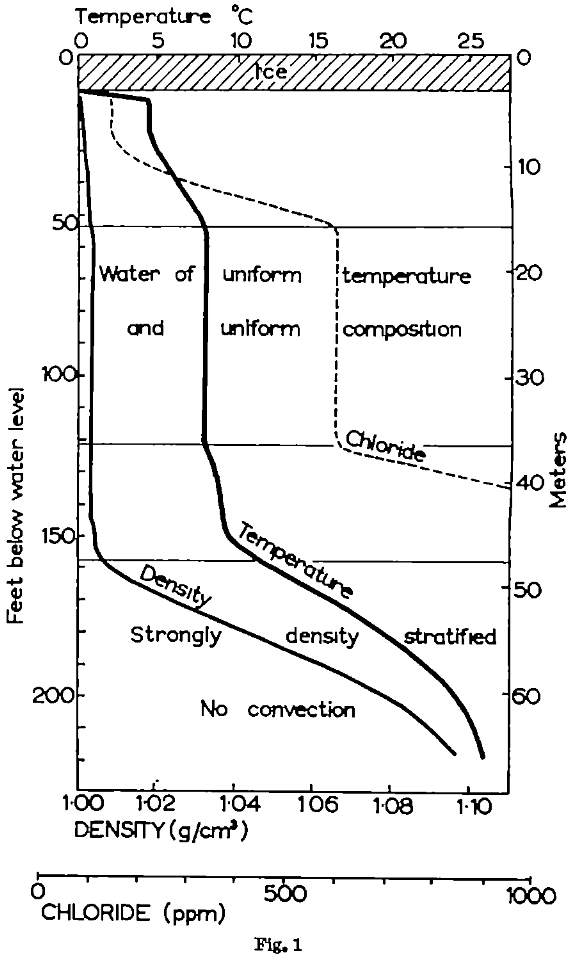

Fig. 1

It is seen that above 190 ft. the temperature-gradient versus depth profile is as would be expected from a solar heating mechanism. At 195 ft. the temperature-gradient falls off more rapidly than is predicted from theory, but it was observed while sampling that the water below 195 ft. is brown in colour.

It is interesting to speculate on the construction of similar installations for the trapping and storing of solar energy in the more temperate latitudes. The heat could then be used for the heating of buildings or for evaporation processes such as salt production from sea-water. Some experimentation along these lines has been carried out in Israel[6].

Ecology of Lake Vanda

During a recent investigation of the chemistry and heat balance of Lake Vanda, *Phormidium* and other blue-green algae were accidentally collected on a nylon line. The algae were collected only in a strongly convective layer. We wish to report this interesting ecological situation and also the novel manner by which these algae were collected.

Armitage and House[1], during a limnological survey in the summer of 1960–61, found that the water at the bottom of the Lake was at 22° C and strongly saline. They obtained only one organism, a *Chlorella*-like alga, from the filtration of more than 100 gallons of Lake water.

Our work in the summer of 1961–62 (previous section) made it likely that the bottom water is warmed by solar radiation. The bottom water is prevented from convecting by its strong density stratification.

The main layers in the Lake are shown by Fig. 1. The top layer is the 12 ft. of ice. The waters from 12 ft. to 55 ft. and from 125 ft. to 160 ft. have a salt gradient and are weakly density stratified. From 55 ft. to 125 ft. the temperature and chemical composition are uniform and this part is considered to be most strongly convective.

While making measurements on the heat balance of the Lake equipment was frequently suspended from nylon monofilaments. If these lines were allowed to remain in position for 24 h a red material was found to accumulate on that part of the line that had been between 55 ft. and 125 ft. This material froze as it came into the air and accumulated at the eyelet of the winding reel. A sample of this material was examined by the biological staff at McMurdo base and was identified as being principally *Phormidium* with a few *Chroocuccus*, and a few *Anabaena*. One live rotifer was present.

It appears that these algae live in a strongly convective layer isolated from the surface of the Lake (mean annual temperature, 20° C) by 50 ft. of colder less saline water and by 12 ft. of ice. Their environment is an almost uniform 7·8° C, their nutrient medium almost isotonic, with 600 p.p.m. Cl', 120 p.p.m. Na^+, 37 p.p.m. K^+, 14 m.equiv./l. Ca^{++}, 3 m.equiv./l. Mg^{++} and 1·3 m.equiv./l. HCO_3'; its available energy from sunlight is about 1,000 cal/cm^2/yr., mostly in the blue part of the spectrum and all during the summer months.

We thank David Mason, John Bunt and Dr. C. R. Goldman for identifying the micro-organisms, Mr. C. J. Banwell, and Mr. I. C. Donaldson and other members of the staff of the Department of Scientific and Industrial Research for helpful advice and for the loan of equipment; also Dr. Angino of the University of Kansas, the U.S. Navy and the U.S.A.R.P. personnel without whose co-operation the expedition would not have been possible.

STRUCTURE OF LYSOZYME

A Fourier Map of the Electron Density at 6 Å Resolution obtained by X-ray Diffraction

The enzyme lysozyme, discovered by Fleming in 1922[1], is responsible for "the power of rapidly dissolving certain bacteria which is possessed by many animal and vegetable tissues and secretions, and to a very marked degree by egg-white". Intensive study by many workers[2–5] has shown that the enzyme attacks a mucopolysaccharide component of bacterial cell walls, liberating acetyl-amino sugars derived from glucosamine and muramic acid. The reaction appears to involve the breaking of a β-glycosidic linkage.

Chemical analysis of hen egg-white lysozyme has shown that the molecule consists of a single polypeptide chain of about 129 amino-acid residues, cross-linked by four disulphide bridges. The amino-acid sequence is known in some detail but the positions of the disulphide bridges have not yet been determined[6,7].

We have now begun a detailed X-ray crystallographic investigation of the structure of hen egg-white lysozyme which we hope will lead to a knowledge of the molecular configuration; this would be of especial interest in connexion with the mechanism of cell lysis and the structure of cell walls. The first result, which is described here, is a three-dimensional electron-density map at 6 Å resolution of lysozyme in the tetragonal crystal form.

X-ray methods. Earlier crystallographic investigations[8–11] have shown that egg-white lysozyme can be crystallized in several crystal forms as the salts of mineral acids. Crystals of lysozyme chloride grown at *p*H 4·7 (ref. 8) are tetragonal with cell dimensions $a = b = 79{\cdot}1$, $c = 37{\cdot}9$ Å and space group $P4_12_12$ or $P4_32_12$. Each unit cell contains eight lysozyme molecules (one per asymmetric unit), molecular weight about 14,600, together with 1 M sodium chloride solution which contributes about 33·5 per cent of the weight of the crystal[10].

The structure has been determined at 6 Å resolution by the method of isomorphous replacement which was used successfully in the study of myoglobin[12,13] and hæmoglobin[14]. Several types of heavy-atom derivatives have been prepared[15] of which three have been used in the present investigation, those containing: (1) mercuri-iodide; (2) chloro-palladite, $PdCl_4$;

* Centric 0,1,2*kl* reflexions only.
† *hk*0 reflexions only.

(3) *ortho*-mercurihydroxytoluene *para*-sulphonic acid (MHTS).

The positions of each of the heavy atoms were found independently from the centrosymmetric projections by using Patterson and Fourier difference syntheses in the standard way. Determination of the relative positions of the heavy-atoms was facilitated by the fact that in this space-group the projections on (001), (100) and (110) are all centrosymmetric. As a result 173 of the 393 reflexions from planes with spacings ⩾6 Å have heavy-atom contributions exactly in or exactly out of phase with the protein contributions to the structure factors. Hart's method[16] was used with these centric reflexions to refine the heavy-atom parameters, the final values of which are shown in Table 1. The absolute scale of intensities is approximate.

The MHTS and $PdCl_4$ are at single sites in general positions. The mercuri–iodide complex, however, is in a special position on a two-fold rotation axis and at this resolution the group was found to be best represented by two isotropic 'atoms' lying on the axis at a distance of 5·6 Å apart. Use of the mercuri–iodide derivative was further complicated by the fact that the heavy-atom content diminished during exposure to X-rays. Measurements from the two crystals of this derivative were therefore treated separately (with appropriate weighting) and their site occupancies were made a function of exposure time in the phase calculations. There were no significant indications that the mercuri–iodide migrated to another discrete site.

Three-dimensional data for two crystals of each type were measured by means of the linear diffractometer[17] and all the data processing and phase calculations were made on a Ferranti *Mercury* computer with specially developed programmes. The phases of the reflexions were determined systematically by the phase-probability method[18,19]. The differences in intensity between reflexions *hkl* and *khl* from the heavy-atom derivatives, which are due to anomalous dispersion, were taken into account in these phase calculations[20] and were also used to distinguish between the enantiomorphous space groups. This analysis has shown that the space group is $P4_32_12$, that is, that the four-fold screw axis is left handed.

The quality of the phase determination is indicated by the measure of agreement between the angles indicated by the different heavy-atom derivatives taken separately. For the acentric reflexions the mean 'figure of merit'[18,19] is 0·79, a value which compares favourably with that obtained in the study of hæmoglobin[14]. The mean 'figure of merit' for the centric reflexions, on the other hand, is 0·95, so that the overall value is 0·86. A check on the sign determinations for the centric reflexions is obtained by direct comparison of the three separate sign predictions. These are compared in Table 2, again with satisfactory results.

Table 2. SIGN DETERMINATION FOR CENTRIC REFLEXIONS

Heavy atom	$PdCl_4$	MHTS	Mercuri-iodide
Predictions agree with 'best' signs (ref. 18)	144	129	102
Predictions disagree significantly*	6	10	12

* A prediction is classed as significant when the calculated heavy-atom contribution ⩾ E (cf. Table 1).

Electron-density distribution. The electron-density distribution was calculated on *Mercury* with structure amplitudes weighted by the figures of merit so as to give the 'best' Fourier[18]. The map has been plotted on a stack of 'Perspex' sheets in the usual way, and a photograph of it is shown in Fig. 1.

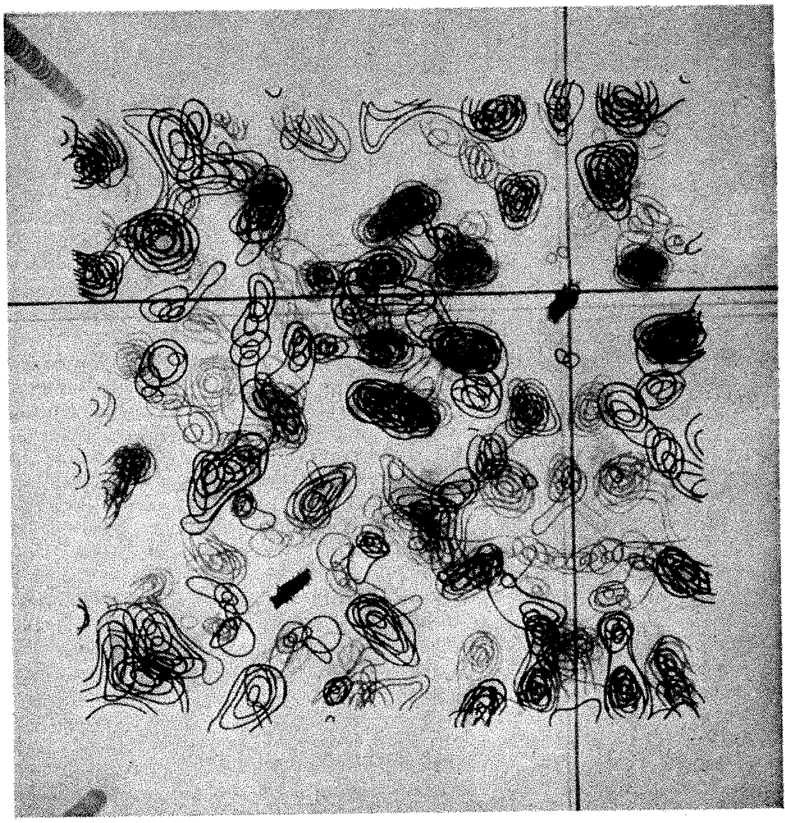

Fig. 1. Electron density distribution in lysozyme, view from above the stack of 'Perspex' sheets, that is, parallel to *c*. The horizontal and vertical lines represent the two-fold rotation axes and intersect the two-fold screw axis, upper right of centre. The four-fold screw axis is at the lower left of centre. The contour interval is 0·07 electron/Å^3, the lowest heavy contour being at 0·6 electron/Å^3. The absolute scale is approximate

Our first object in studying this map was to determine the boundary of a single molecule. Comparison of the unit-cells of various crystal forms of lysozyme[10] suggests that in tegragonal lysozyme the molecule occupies the full length of the c-axis and, on average, one-eighth of the area of the ab-plane. On this basis, the map of Fig. 1 includes the whole of the c-axis and a sufficient area of each section to ensure that one whole molecule is included in addition to parts of neighbouring molecules. Only contours indicating where the electron density is greater than average are included.

Some featureless regions of average electron density (0·4 electron/Å^{-3}), probably occupied by liquid between molecules, are immediately apparent. The most marked of these is around the two-fold screw axis parallel to c. This axis is intersected at intervals of 9·5 Å by two-fold rotation axes, and packing considerations, therefore, make it impossible for substantial portions of the molecules to penetrate into the neighbourhood. It is encouraging to find it so free from detail. Similarly, the immediate vicinity of the four-fold screw axis also is void of significant features and must be a region of intermolecular space. The two-fold rotation axes help to determine the boundary, particularly where relatively high density approaches or intersects them as it does at two places. Such regions must represent close contact or bridges between adjacent molecules.

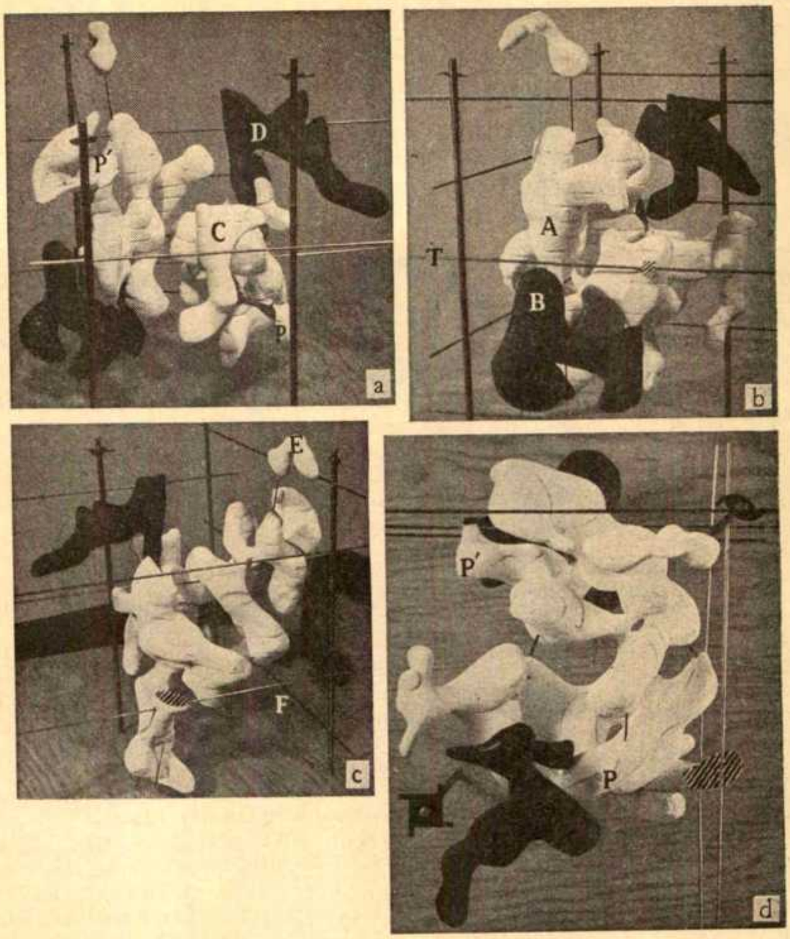

Fig. 2. Several views of a model of the regions in which the electron density exceeds about 0·53 electron/Å^3. The vertical rods indicate the two-fold and four-fold screw axes parallel to c. The thinner horizontal rods are two-fold rotation axes. At two places, shown hatched, rotation axes pass through continuous regions of density. The white regions alone make up the most compact asymmetric unit of the structure. In Fig. 2b, the grey section (B) is alternative to the region (A) to which it is related by the two-fold axis T. In Fig. 2a, the grey section (D) is alternative to the white (C), related by the four-fold screw axis. The grey piece (F) in Fig. 2c is alternative to the white E, to which it is related by a unit cell translation along c. The scale is indicated by the framework of symmetry elements, adjacent parallel two-fold axes being 18·95 Å apart

Some regions remain, however, in which the boundary of a single molecule cannot be decided unequivocally. The most serious difficulties are illustrated by the model shown in Fig. 2, which represents the volume occupied by density greater than about 0·53 electron/Å^3. One asymmetric unit is shown in white with additional pieces in grey to show alternative shapes. The white pieces together make up the most compact asymmetric unit, which is roughly ellipsoidal in shape with axes 52 × 32 × 26 Å. This asymmetric unit may also represent a single molecule, but we cannot be certain that it does and the alternatives include at least one major variation. Fig. 2a and d show that there is a region of low density dividing the model roughly into two halves. These parts could in fact be assembled differently, following the crystal symmetry, so as to form a dumb-bell-shaped molecule connected at PP'. This seems rather an improbable shape, but the possibility cannot be entirely ignored.

Our second object is to determine so far as possible the course of the polypeptide chain and the positions of the disulphide bridges, that is, the tertiary structure, and to correlate our result with what is known of the primary structure[6,7]. This has proved to be difficult if not impossible at this stage. In comparison with the maps of myoglobin[12] and hæmoglobin[14] at this resolution it is apparent that our map of lysozyme has a much smaller proportion of clear-cut rod-like features representing helical configurations of the polypeptide chain. This is not surprising since optical-rotatory-dispersion measurements[21] and other X-ray evidence[22] suggest that only 30–40 per cent of the polypeptide chain in lysozyme is in the form of α-helix as compared with 77 per cent in myoglobin. Tracing the course of the chain, which was not completely straightforward in myoglobin[12], is therefore much more difficult here since non-helical portions of chain appear at much lower density and are often not easily discernible. The task is further complicated by the presence of the disulphide bridges, which are expected to have about the same electron density as α-helix at this resolution and which are bound to make the chain appear branched. In fact there are some branches in the density which are suggestive of disulphide bridges and there is sufficient continuity to set close limits on the possible configurations of the polypeptide chain. We consider, however, that it would be misleading to discuss these possibilities further or to suggest a tertiary structure until we have determined the molecular boundary with more certainty, by increasing the resolution of our analysis and by comparing our results with those obtained by other workers.

An X-ray crystallographic study of tetragonal lysozyme chloride crystals containing complex ions of niobium and tantalum is in progress at the California Institute of Technology[23] and through the courtesy of Prof. Corey *et al.* we have been able to compare their results with our own. In this comparison allowance must be made for the facts that: (1) the niobium-containing crystals are not quite isomorphous with ours, at least the orientation of the lysozyme molecules has been changed by the inclusion of the heavy-atom group; (2) the Californian analysis is at 5 Å rather than 6 Å resolution and is based in effect on one isomorphous heavy-atom derivative; (3) the map (Fig. 1 in the following article) has been plotted in the space group $P4_12_12$. When allowance is made for these differences the two maps are found to be in satisfactory agreement with many features in common.

An examination of triclinic lysozyme nitrate is in progress at the University of Illinois and through the courtesy of Drs. Dickerson and Steinrauf[24] we are also comparing their map with ours. The results of both these comparisons will be described in detail elsewhere.

We thank Sir Lawrence Bragg and Prof. R. King for their interest and encouragement; the Director of the University of London Computer Unit for computing facilities on *Mercury*; and Mrs. W. Browne, Mrs. A. Hartley, and Miss D. Glass for their assistance with data collection and computation. We also thank the U.S. National Institutes of Health for financial assistance.

An X-ray Investigation of Lysozyme Chloride Crystals containing Complex Ions of Niobium and Tantalum : Three-dimensional Fourier Plot obtained from Data extending to a Minimum Spacing of 5 Å

THE first X-ray investigations of egg-white lysozyme chloride were made by Palmer[1,2] in 1948. He reported that both wet and air-dried crystals are tetragonal, space group $P4_12_1$ or $P4_32_1$, with eight molecules per unit cell, one per asymmetric unit; $a = 79{\cdot}1$, $c = 37{\cdot}9$ Å (wet); $a = 71{\cdot}2$, $c = 31{\cdot}4$ Å (dry). A later investigation[3] of the air-dried crystals provided no information about the structure of the molecule. More recently, we have been engaged in an examination of the structure of lysozyme chloride by use of isomorphous series of crystals containing heavy ions; a preliminary report of this work is in print[4]. An investigation of lysozyme chloride is also in progress in the Davy Faraday Laboratory of the Royal Institution[5], and crystals of triclinic lysozyme nitrate are being investigated at the University of Illinois[6,7].

So far, our work has been based on crystals containing the complex ions of tantalum and niobium $Ta_6Cl_{12}^{++}$ and $Nb_6Cl_{12}^{++}$. These crystals (hereafter referred to as LTa and LNb) are highly isomorphous as shown by careful measurements of their unit cell dimensions, which, however, differ significantly (1–3 per cent) from those of lysozyme chloride alone. Calculations based on accurate measurements of the densities of these crystals, and confirmed by chemical analyses, indicate that they contain eight complex ions per unit cell, or one per lysozyme molecule. Successive two-dimensional and three-dimensional difference Patterson maps calculated from data extending to a minimum spacing of 5 Å served to determine the positions of the centres of the complex ions. Calculations based on these co-ordinates were used in the adjustment of the values of F_{obs} to the absolute scale. For the 186 centrosymmetric $hk0$ and $h0l$ reflexions corresponding to a minimum spacing of 5 Å, the discrepancy factor R is 0·26 where:

$$R = \frac{\Sigma \big|\, |\Delta F|_{\text{obs}} - |\Delta F|_{\text{calc}} \,\big|}{\Sigma |\Delta F|_{\text{obs}}}$$

and:

$$|\Delta F|_{\text{obs}} = |F_{\text{LTa}} \pm F_{\text{LNb}}|$$

$$|\Delta F|_{\text{calc}} = |F_{\text{Ta}}| - |F_{\text{Nb}}|$$

Bearing in mind that the terms ΔF_{obs} are differences between observed quantities, the small value of this factor gives strong support to the conclusions that the crystals are indeed isomorphous and that the centres of the ions have been correctly located. Corresponding attempts to adjust the scale of the lysozyme hydrochloride data to those of the crystals

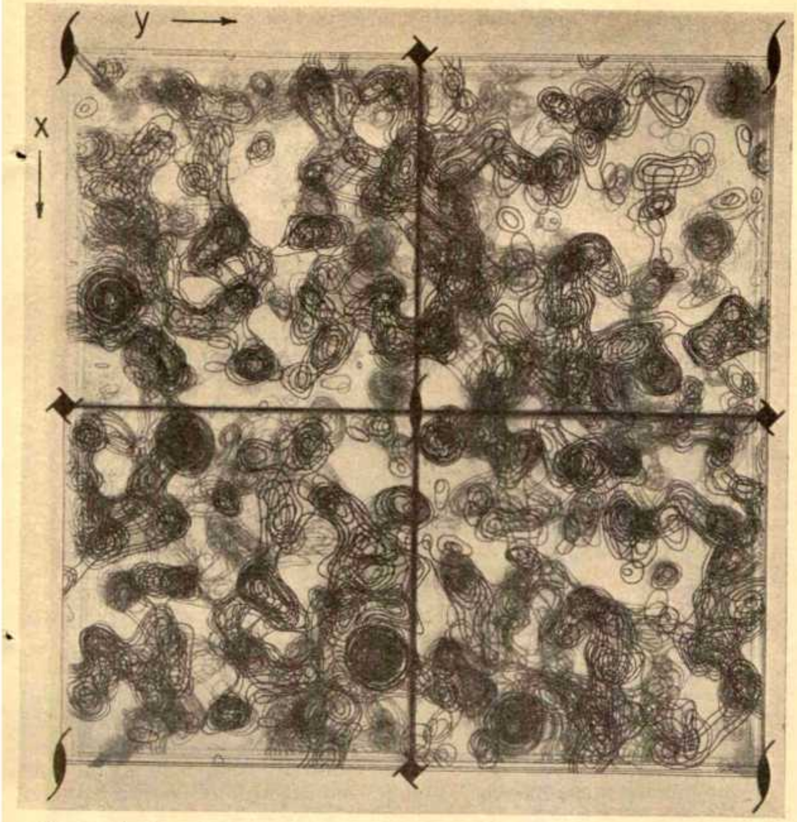

Fig. 1. A view of a portion ($z=0$ to 1/2) of the three-dimensional weighted Fourier diagram of lysozyme–Ta_6Cl_{14} calculated with the phase angles of the Ta_6 octahedron. Contours are drawn at equal but arbitrary intervals. The top layer corresponds to $z=0{\cdot}50$

containing the complex ions were unsuccessful, indicating that the complex ions cause a significant spatial alteration in the protein molecule. Two-dimensional Fourier projections[4] of electron density on to 010 and 001 of LTa crystals failed to provide information about the protein molecule.

We have now extended this investigation by the calculation of two three-dimensional Fourier syntheses of electron density based on 625 *hkl* reflexions ($d_{\min} = 5$ Å) from crystals of LTa and LNb. In the complex ions the atoms of tantalum and niobium are arranged at the six corners of a regular octahedron[8], and it has been shown[9] that, for reflexions extending to a minimum spacing of 5 Å, the combined scattering by these atoms is practically independent of the orientation of the octahedron. An arbitrary orientation was therefore assumed for purposes of calculation. The scattering powers of tantalum and niobium, which were taken from the *International Tables*[10], were corrected for the real part of the anomalous dispersion[11]. An isotropic temperature factor $B = 30{\cdot}6$ was also applied. The positions of the complex ions were used to calculate the quantities:

$$\Delta F_c = F_c(\mathrm{Ta}) - F_c(\mathrm{Nb})$$

and:

$$A_c(\mathrm{Ta\text{–}Nb}),\ B_c(\mathrm{Ta\text{–}Nb})$$

which represent the amplitudes and phase angles, respectively, of the vector differences between the contributions of the tantalum and niobium atoms.

In our first three-dimensional Fourier synthesis, the quantities $A_c(\mathrm{Ta\text{–}Nb})$ and $B_c(\mathrm{Ta\text{–}Nb})$ which, of course, were also equivalent to the phase angles of the $Ta_6Cl_{12}^{++}$ contribution, were applied directly to the scaled absolute values $|F_0(\mathrm{LTa})|$ of the amplitudes of reflexions from crystals of LTa. Thus, in these calculations:

$$A_0(\mathrm{LTa}) = \frac{A_c(\mathrm{Ta\text{–}Nb})}{|\Delta F_c|} \times |F_0(\mathrm{LTa})|$$

and:

$$B_0(\mathrm{LTa}) = \frac{B_c(\mathrm{Ta\text{–}Nb})}{|\Delta F_c|} \times |F_0(\mathrm{LTa})|$$

The 625 *hkl* reflexions with minimum spacing of 5 Å included 104 *hk*0, 82 *h*0*l*, and 62 *hhl* for which the phase angles are 0, $\pm\pi/4$, $\pm\pi/2$, $\pm 3\pi/4$, or π, and hence could be quite unambiguously assigned by inspection of the intensity data.

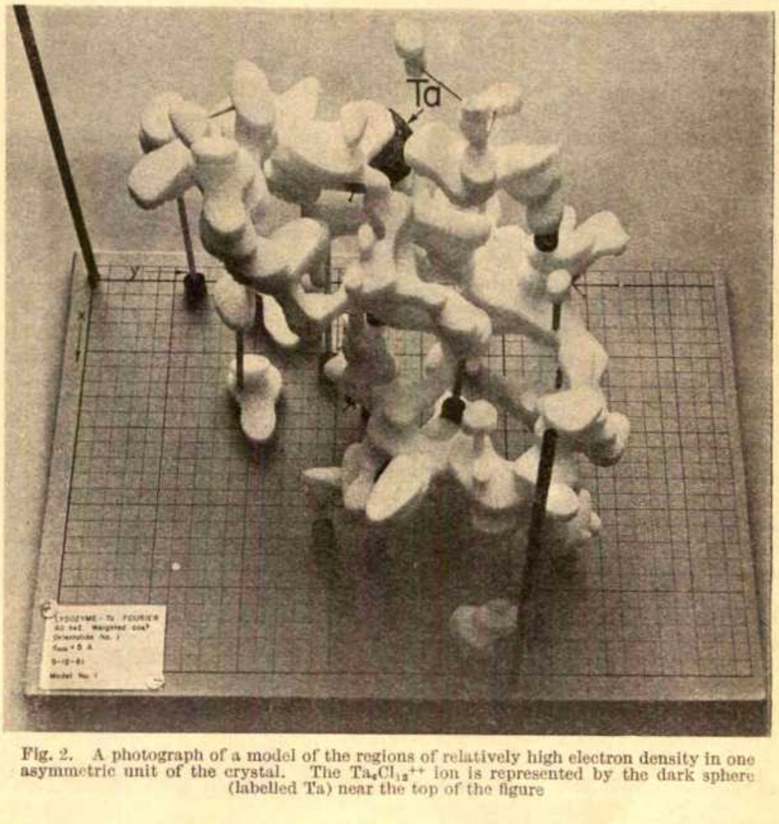

Fig. 2. A photograph of a model of the regions of relatively high electron density in one asymmetric unit of the crystal. The $Ta_6Cl_{12}^{++}$ ion is represented by the dark sphere (labelled Ta) near the top of the figure

For the remaining 377 reflexions, or 60 per cent of the data, the choice of phase angle rested between two ambiguous values. It is to this last class of reflexions that we have applied the phase angles which were derived from the positions of the heavy atoms and were therefore intermediate between the ambiguous values.

In spite of these approximations in the phase angles, the plot of this Fourier contained interesting features which appear to have some significance. The $Ta_6Cl_{12}^{++}$ ion was roughly spherical, and the contours throughout the remaining portions of the plot showed continuous regions of high density which suggested portions of a polypeptide chain, possibly in the α-helix configuration.

The second three-dimensional Fourier was calculated in an attempt to reduce the effects of the errors in phase angles present in the first Fourier. In this calculation the values of A_0(LTa) and B_0(LTa) were weighted with a factor $\cos^3 \varphi$ in which φ is the difference between the phase angle of the heavy-ion contribution and the ambiguous phase angles of the total lysozyme–$Ta_6Cl_{12}^{++}$ complex. From the terms A_c(Ta–Nb), B_c(Ta–Nb), and $|\Delta F_c|$ defined here, and the observational results from the two types of crystals, $|F_0(\text{LTa})|$ and $|F_0(\text{LNb})|$, the ambiguous phase angles of the reflexions from LTa and LNb crystals were calculated; from these the values of φ and $\cos^3 \varphi$ were computed. The effect of this weighting factor, $\cos^3 \varphi$, is to compensate in some degree for the errors inherent in the first Fourier by giving relatively high weight to those reflexions for which the true phase angle differs little from the assumed phase angle and causing the weight to fall off rapidly as this difference increases.

In the calculation of both Fourier syntheses the F_{000} terms were omitted, and in the plots the contours were drawn at equal but arbitrary intervals. The plot of the weighted Fourier (Fig. 1) is conspicuously clearer than that of the unweighted one. The $Ta_6Cl_{12}^{++}$ ion is very close to spherical, although slightly flattened in the direction of the c axis. The continuous regions of high density in other portions of the plot are also better defined, and more suggestive of coiling or folding of polypeptide chains than are those in the unweighted plot. A photograph of a portion (z = 0 to 1/2) of the plot of the weighted three-dimensional Fourier is shown in Fig. 1. The positions of the complex ions are clearly shown as spherical groups of contours near the four-fold screw axes at the bottom and left side of the figure.

Fig. 2 is a photograph of a 'Styrofoam' model of the regions of relatively high density in one asymmetric unit selected with a view to represent the volume perhaps occupied by a single molecule of lysozyme. The position of the $Ta_6Cl_{12}^{++}$ ion is shown by the dark sphere, Ta, near the top of the figure. Although the presence of continuous regions of high electron density is strongly suggestive of a polypeptide chain in a folded configuration, the analysis must be carried much further before this interpretation can be considered to be established.

We thank Mr. Robert E. Long and Mr. Harold D. Nathan for assistance with the calculations and to Miss Lillian Casler for the preparation of the three-dimensional Fourier models.

This work was supported principally by a contract (*Nonr*-220(38)) between the U.S. Office of Naval Research and the California Institute of Technology; it was also aided by research grant No. *H*-2143 from the National Heart Institute, U.S. Public Health Service, and by grant No. 9467 from the National Science Foundation.

A 6 Å Model of Triclinic Lysozyme

WE have recently calculated in this laboratory a three-dimensional structure of triclinic lysozyme nitrate to a resolution of 6 Å, using three isomorphous heavy atom derivatives: $HgI_4^{=}$, $HgBr_4^{=}$ and $PtCl_6^{=}$. The space group is $P1$ with one molecule per unit cell, and there were found to be five, six and six heavy atom occupancy sites per molecule respectively for this crystal form. The mean figure of merit from the centroid phase determination is 0·85, and the mean lack-of-closure error of the phase triangles or 'R factor' as defined by Kraut[1] is 6–7 per cent for each derivative.

This is the first time that the multiple isomorphous replacement method has been tried with structures having no centrosymmetric projections and with multiple-site derivatives of this nature. Two questions of fundamental importance have been raised about such an analysis: (*a*) To what extent can one be sure of obtaining the correct heavy atom positions from three-dimensional $(\Delta F)^2$-type approximate Patterson functions in the absence of centrosymmetric projections to serve as a check ?

(*b*) With the large number of sites per molecule and hence with a large number of parametric degrees of freedom, can one exclude the possibility of falling into a false structure which would still produce reasonable phase circles and a high figure of merit ? As part of a programme to test these points, work is now in progress which will lead to a redetermination of the structure using the most favourable new derivatives selected from a screening of about two dozen. It is hoped that this work will resolve questions concerning both the structure and the validity of the methods used.

A complete account of this structure will be presented at a later date.

MORPHOLOGY AND DEVELOPMENT OF RESPIRATORY SYNCYTIAL VIRUS IN CELL CULTURES

By Dr. J. A. ARMSTRONG, Dr. H. G. PEREIRA and Dr. R. C. VALENTINE

National Institute for Medical Research, London, N.W.7

RESPIRATORY syncytial (RS) virus was first described under the name of 'chimpanzee coryza agent' by Morris *et al.*[1] in 1956. Later, it was isolated from infants with severe respiratory infections[2], and its importance in the ætiology of human respiratory illnesses is firmly established[3,4]. The virus is ether-sensitive and its size has been estimated as roughly 90–130 mμ[2]. It multiplies in cultured cells causing the formation of syncytial masses with eosinophilic cytoplasmic inclusions, and recently it was suggested that this virus may be included among the larger myxoviruses[5]. This view derives some support from observations we have made on the fine structure of infected epithelial cells.

HeLa cell cultures were maintained and used for virus propagation as previously described[6]. Tube cultures containing 50,000–100,000 cells were inoculated with approximately $10^{4 \cdot 5} TCD_{50}$ of the Long strain of RS virus and incubated at 37° C without rotation. Visible cytopathic changes followed the pattern of earlier descriptions: multinucleate cells were detectable after 24 h, and by 48 h the syncytia were large and numerous. The cell sheets then rapidly disintegrated. Cultures inoculated 46 h previously were selected, with uninoculated controls, for cytological study by light and electron microscopy. Coverslip monolayers were prepared for phase-contrast microscopy by the method of OsO_4-fixation and ethanol reduction[7], and were mounted in water. Feulgen and periodic acid–Schiff techniques were carried out after osmium-fixation, and Bouin-fixed cultures were stained with hæmatoxylin and eosin.

Phase-contrast microscopy showed a substantial area of the inoculated monolayers consisting of large syncytia, each with 30 or more nuclei deployed in annular fashion or in clumps towards the centre of the cell mass. There were many multinucleate forms of smaller sizes and also a number of persisting individual cells with only one nucleus. The single cells were usually spindle shaped and provided with elaborately branching cytoplasmic processes. Rounded cytoplasmic inclusions, measuring up to 10μ across but of only moderate optical density, were present in great numbers throughout the cultures. After fixation in Bouin's fluid the spindle cells were mostly retracted, and typical shrinkage spaces had formed around the inclusions. The latter stained with eosin but were Feulgen and periodic acid–Schiff-negative.

For electron microscopy cultures were fixed with Palade's 1 per cent OsO_4 solution at *p*H 7·4, and embedded as loose pellets in methacrylate or in 'Vestopal *W*'. Ultra-thin sections were stained with uranyl acetate or lead hydroxide and examined with Philips *EM* 75*B* and Siemens *UM* 100 electron microscopes. Abnormalities of fine structure found regularly in electron micrographs of the inoculated cultures can be summarized under three headings: (*a*) the cell wall; (*b*) cytoplasmic inclusions; (*c*) the cell nuclei.

The cell wall. Spindle cells and the smaller syncytia presented an abnormal degree of folding and irregularity of the cell membrane. Sections revealed numerous extracellular particles which were virus-like in their size, morphology and electron density (Fig. 1). Close inspection of the particle aggregates demonstrated not only circular profiles but many that were elongated. A typical round form is shown in Fig. 2*a*. It consists of a dense central core about 20 mμ in diameter enclosed within a zone of relatively low density; this is surrounded by a dense outer ring some 15 mμ in thickness, giving a total particle diameter of about 65 mμ. Sometimes the core had an irregular outline or appeared as two or three separate parts (Fig. 2*b*). Certain profiles gave the impression of a diffuse layer external to the dense ring.

The most elongated profiles were clearly filamentous structures cut longitudinally, and the others were attributable to oblique sectioning of similar forms (Figs. 1 and 2*c*). Filaments up to 2·5μ in length could be measured; but maximum lengths could not be determined by inspection of random sections.

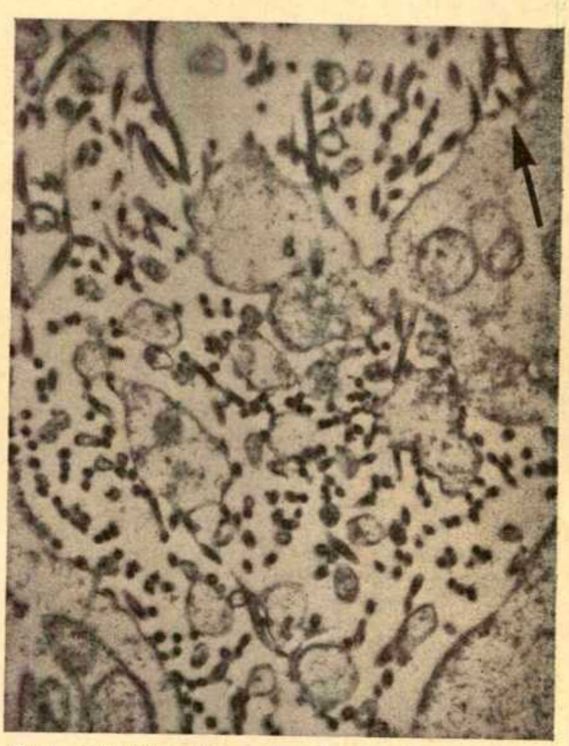

Fig. 1. Virus-like particles at the cell surface 46 h after inoculation. Some elongated profiles (arrow) are continuous with the cell membrane. (× 14,000)

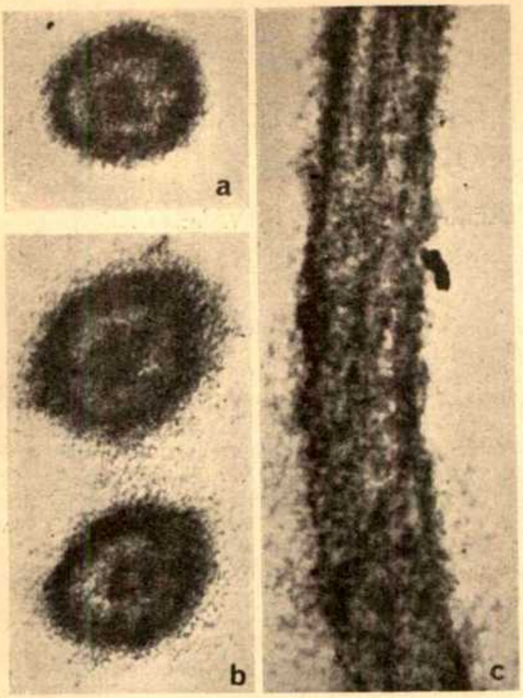

Fig. 2. Sectioned particles at high magnification: *a* and *b*, circular profiles; *c*, a filament. (× 300,000)

Some had a vesicular swelling at, or near to, their distal extremities. Proximally, continuity of the filaments with the host cell membrane was frequently revealed. There was no difficulty in distinguishing the filaments from microvilli. Having a uniform width of between 60 and 70 mμ, they were bounded by a layer of exceptionally high density. Each contained a central thread-like element, usually forming a dense core about 20 mμ thick but at some points appearing to consist of separate strands or even to be tubular. Transection of filaments would naturally account for at least some of the circular profiles in the micrographs; indeed, we are forced to conclude that truly spherical particles amounted, at the most, to a minority of those actually seen.

The number of associated virus-like particles noticeably diminished with increasing size of the syncytia examined, the largest examples of which had smooth and particle-free surface membranes.

Cytoplasmic inclusions. These consisted of masses of abnormal material up to several microns in diameter, with no limiting membrane. Their distribution approximated to that of the eosinophilic bodies seen by light microscopy, but at the fine structural level they were evidently of two types. One was invariably paranuclear and comprised a fine fibrillar matrix, while the other type was more widespread, more sharply demarcated from the surrounding cytoplasm, and composed of dense material of an amorphous or granular nature (Fig. 3). Mononuclear spindle cells had only occasional inclusions, of the fibrillar type, whereas the syncytia contained a profusion of both types of inclusion. Virus-like particles were never seen in the inclusions or elsewhere within the cells.

The cell nuclei. Large and bizarre nucleoli were a feature of the inoculated cultures. Well-defined dense areas in the nucleoplasm amounting to veritable inclusions were also present, but these occurred only in the largest syncytia (Fig. 4). That the inclusions were not merely manifestations of nuclear degeneration was evident from their uniformity and the intact condition of the nuclei concerned. The inclusions were always in contact with some part of the nuclear envelope, yet at the same time related closely to the nucleolus. At high magnifications they were seen to consist of a network similar to that of the fibrillar cytoplasmic inclusions. Patches of this nature were also located in small cavities within the nucleoli, suggesting a possible nucleolar origin for the inclusion material.

It would appear from these results that RS virus, at least in some circumstances, exists in the form of filaments measuring about 65 mμ across and developing at the host cell surface in the manner of myxoviruses. Supporting evidence was obtained by electron microscopy of disrupted cells, using the phosphotungstate negative contrast method of Horne and Nagington[8]. Filaments were observed measuring 50 mμ across and up to 2μ in length; they possessed an outer layer of projecting 'spikes' similar to, but rather longer than, those characterizing the myxoviruses. The diameter of RS virus particles as measured by electron microscopy is somewhat less than the original estimate (90–130 mμ) derived from sucrose density sedimentation data[2]. In dealing with a population that is largely filamentous in form it is inevitably difficult, in sections, to identify truly spherical particles with certainty; thus the occurrence of RS virus in the form of both filaments and spheres, as with certain strains of influenza virus, is not excluded by the present observations.

The cell cultures exhibited a progression of cytological alterations, from occasional normal cells to the largest syncytia, on the basis of which the following cytopathic sequence is proposed: (1) New virus particles emerge from the surface of individual spindle cells, inside which the only obvious changes are nucleolar enlargement and occasional fibrillar cyto-

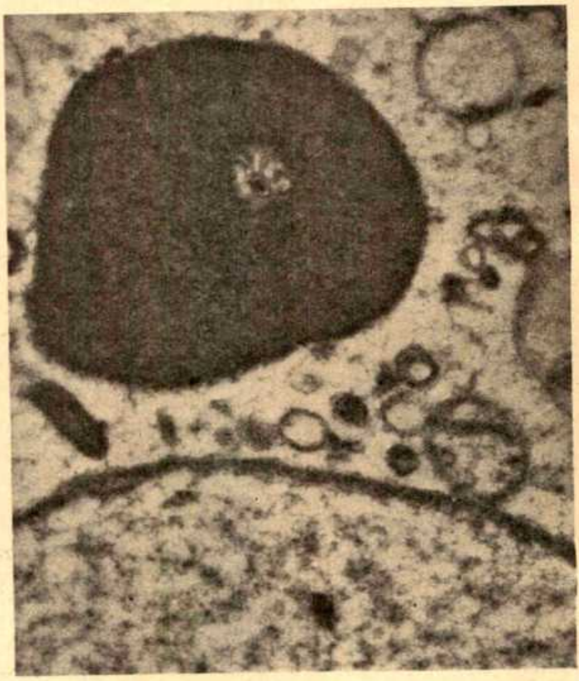

Fig. 3. A cytoplasmic inclusion of the dense type, near to a nucleus in a syncytial cell mass. (× 25,000)

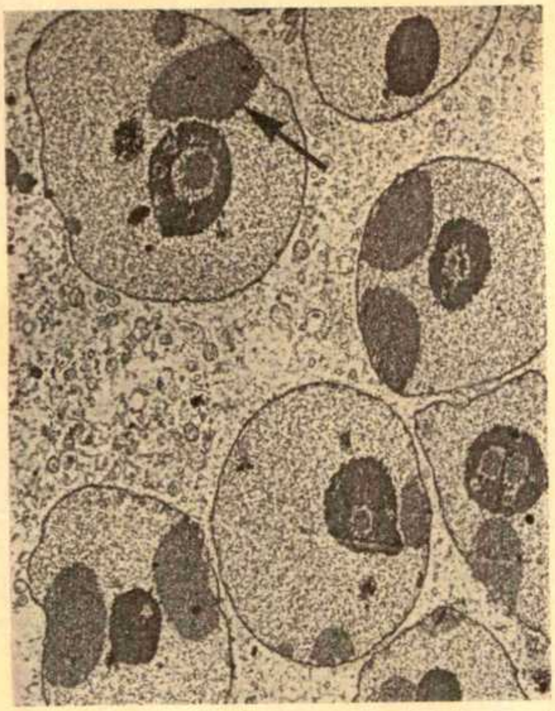

Fig. 4. Survey micrograph showing intranuclear inclusions (arrow) in a large syncytium. (× 3,000)

plasmic inclusions. (2) Incorporation of the cells into small syncytia is followed at first by continued production of virus particles and an increase of cytoplasmic inclusions. (3) Syncytial enlargement is accompanied by cessation of particle production, disruption of cytoplasmic fine structure, and the appearance of intranuclear inclusions.

Fluorescent antibody investigations suggest that at least some of the cytoplasmic inclusions contain viral antigen, but fluorescence was not observed in the host cell nuclei[5,9]. The present findings exclude the occurrence of organized virus particles in the cytoplasmic and nuclear inclusions, the significance of which is still uncertain. We favour the view that formation of discrete inclusions, and also the tendency to syncytium formation, are effects consequent on, rather than leading to, the synthesis of new virus. It is of some interest that the intranuclear inclusions were not discernible by light microscopy, in spite of their large size.

With regard to classification, the morphology of RS virus and its mechanisms of maturation and liberation seem to resemble more closely those of myxoviruses[10–12] than of any other group. Nevertheless, thin sections of influenza virus filaments give no sign of internal structure[10] whereas the filaments seen here had a well-developed core. Also, RS virus lacks the properties of hæmadsorption and hæmagglutination[2,3], and fails to multiply in the hen's egg[2]; and no serological relationship with known myxoviruses has so far been discovered[13]. Chemical analysis of RS virus has yet to be done. In view of these considerations, we are inclined to reserve judgment on the taxonomic issue, while recognizing the convenience of regarding this virus provisionally as an atypical member of the myxovirus group.

TRANSFER OF SUBSTANCES BETWEEN THE BLOOD AND CENTRAL NERVOUS SYSTEM IN VERTEBRATE AND INVERTEBRATE ANIMALS

By J. E. TREHERNE

Agricultural Research Council Unit of Insect Physiology, Department of Zoology, University of Cambridge

THE nature of the physiological processes involved in the exchanges of substances between the blood and the tissues of the brain has been the subject of some controversy ever since the original observation by Ehrlich[1] that certain aniline dyes stained all the tissues of the body except those of the central nervous system. The site of the blood-brain barrier has been variously identified with the neuroglia, with the 'ground substance' of cerebral tissues and with the capillary endothelium[2–4]. According to this latter concept the similarity of the rates of penetration into cerebral tissues with those demonstrated for single cells has been postulated to result from some special characteristics of the cerebral capillaries which have been supposed to be functionally more analogous to the cell plasma membrane than to those of capillaries in other parts of the body[5].

The direct measurement of transfer processes and the identification of rate-limiting factors is rendered extremely difficult by the complicated structure and organization of the mammalian brain. The purpose of this communication is, therefore, to summarize some results which have been obtained in experiments on the relatively simple arthropod central nervous system and to consider them in relation to the more complex physiological organization of the mammalian brain. The nervous systems of insects and other arthropods differ from those of the vertebrate animals in possessing no internal blood circulation so that, apart from the oxygen carried by tracheoles, all the exchanges of nutrient and excretory substances must take place across the peripheral fibrous and cellular nerve sheath. This superficial position for the exchanges of substances between the insect central nervous system and the hæmolymph makes the study of its permeability properties relatively easy. Furthermore, the diffusion processes occurring within the tissues of the insect central nervous system are likely to be more obvious than those in the mammalian brain as the width of some insect ganglia are measured in thousands of microns as compared with the 20μ or so which represents the maximum distance of any of the cerebral tissues from their associated capillaries.

In the insect central nervous system it has been found that the exchanges of sugars labelled with carbon-14, sodium-24 and potassium-42 occurred relatively rapidly with the hæmolymph[6,7]. In addition, it was shown that the passage across the fibrous and cellular sheath was not a rate-limiting factor for an appreciable proportion of the exchanges of sodium-24 occurring in the cockroach terminal abdominal ganglion[8,9]. The efflux of the slowly exchanging sodium fraction, which was found to be reduced in the presence of metabolic inhibitors or in the absence of potassium ions, was identified with an active extrusion of these ions from the cellular components of the central nervous system[10]. The rapidly exchanging ion fraction was identified with that occurring within the extracellular spaces of the nervous system. This finding was strengthened by the observation that an appreciable portion of the nerve cord water was accessible to inulin molecules labelled with carbon-14 (refs. 10 and 11). The inulin space, of 18·2 per cent, was approximately equivalent to the rapidly exchanging fraction of tritiated water which accounted for 21·6 per cent of the nerve cord water.

By contrast with the mammalian brain the apparent extracellular space in the insect central nervous system demonstrated by the use of labelled ions and molecules was found to approximate to that revealed by electron microscopy. In the cockroach terminal abdominal ganglion the extracellular system was found to consist of an extensive system of fine ramifying channels (about 200 Å in width) throughout the ganglion, together with an irregular series of large cavities (the 'glial lacunar system' of Wigglesworth[12]) towards the periphery of the structure[13,14]. The presence of the glial lacunæ appeared to contribute to the much larger extracellular system demonstrated by electron microscopy in the insect ganglion, as compared with the mammalian brain in which the very *fine* channels only account for some 4 per cent of the total space[15,16].

The extracellular fluid of the cockroach abdominal ganglia has been shown to have a composition which differs from that of the hæmolymph in possessing an excess of cations together with a relatively low level of chloride ions due to the presence of a Donnan equilibrium across the nerve sheath[11,17]. The free anion groups producing the Donnan distribution have been tentatively identified with those of an acid mucopolysaccharide which has been recently demonstrated in the extracellular spaces of cockroach ganglia[18]. The mucopolysaccharide component of cartilage ground substance is known to exclude negatively changed dye molecules such as trypan blue due to the presence of the free anion groups[19]. By analogy with this condition the demonstrated exclusion of trypan blue from the cockroach central nervous system[12] was postulated to be due to the free anion groups associated with the extracellular mucopolysaccharide rather than to any significant properties of the nerve sheath as a diffusion barrier[11].

It is instructive to extend these observations on the arthropod central system to the more complex state of affairs in the mammalian brain. Thus by analogy with the invertebrate nervous system it might be expected that the mammalian cerebral capillary endothelium would be relatively permeable, perhaps being similar to those in other parts of the body. This supposition would be contrary to the hypothesis that the transfer across the capillary wall is a rate-limiting process. This concept is, however, based on very little direct physiological evidence and largely derives from the fact that this structure is morphologically the superficial boundary between the blood and cerebral tissues. An explanation for the apparent slow penetration of water-soluble substances into cerebral tissues can be obtained from a consideration of the fine structure of the extracellular system in the brain. The very limited volume of the extracellular channels demonstrated by electron microscopy, taken into consideration with the very small distances involved for the diffusion from the capillary endothelium to the various cerebral cells, might imply that the extracellular fluid could, as in the arthropod, achieve a relatively rapid equilibrium with the blood plasma, as has been suggested by Edström[20]. Such a small, rapidly exchanging extracellular fraction would be very difficult to demonstrate experimentally and could account for the very small amount of sucrose and other water-soluble substances which are said to enter brain tissues[21-25]. According to this hypothesis the slow penetration into the brain tissues would be due to the relative impermeability of the plasma membranes of the cerebral cells. Thus the close similarity commented on by Krogh[5] for the penetration into the tissues of the brain might not be due to any special properties of the capillaries but to the fact that the measured exchanges are, in fact, largely those taking place across the membranes of the cells which form about 96 per cent of the brain volume.

In the arthropod central nervous system de-sheathing involves a significant increase in the rapidly exchanging ion fractions. This increase was shown to be associated with an enlargement of the measured inulin space and was supposed to result from an enlargement of extracellular spaces or to cellular changes in this preparation[11]. A somewhat similar state of affairs would seem to exist in the mammalian brain where an increased accessibility of sucrose, thiocyanate and iodide has been measured in isolated pieces of brain, or during repeated replacement of the cerebrospinal fluid with Krebs–Ringer solution, as compared with the intravenously infused organ[24,26]. The analogy with the arthropod central nervous system thus supports the concept that the failure of such water-soluble substances to penetrate cerebral tissues in appreciable amounts is due to very restricted extracellular spaces[20], which are increased in abnormal conditions, rather than to the presence of a discrete relatively impermeable blood–brain barrier.

By analogy with the arthropod central nervous system it might also be tentatively postulated that one factor causing the exclusion of various negative dyes from the mammalian brain might be the presence of free anion groups in the restricted extracellular spaces. This postulate would also serve to explain the relatively rapid entry of basic dyes into the cerebral tissues. Mucopolysaccharides, which might be expected to possess free anion groups, have been shown to produce particularly intense staining of the internal elastic lamella of the large arterial and capillary walls[27,28]. Such a distribution could conceivably explain the relatively slow penetration of trypan blue (which possesses four negative charges) obtained on intravenous as compared with intrathecal administration. Any discontinuous distribution of substances containing free anion groups in the general extracellular spaces might thus allow some permeation of the dye molecules following intrathecal administration. These postulates bear some resemblance to the earlier theories which attempted to identify the blood–brain barrier with the 'ground substance' of cerebral tissues.

It has been pointed out that the very restricted extracellular system in the mammalian brain, described by electronmicroscopists as consisting essentially of 200 Å channels between adjacent cells, has been difficult to reconcile with the known minimum metabolic requirements of active nerve cells[8]. In particular, it might be imagined that the amount of sodium ions immediately available in such a restricted extracellular fluid might not be sufficient to sustain prolonged nervous activity. Such difficulties in the interpretation of normal nerve function in the brain are more explicable on the basis of a capillary endothelium which is relatively permeable to cations. Furthermore, if the organization of the extracellular system is similar to that in the arthropod central nervous tissues then it could be postulated that any indiffusible free anion groups might maintain a significant excess of cations which would thus tend to function as a reservoir of sodium ions.

CORRELATION OF DIFFERENT EXCITATORY AND INHIBITORY INFLUENCES ON CELLS IN THE NUCLEUS GRACILIS OF THE CAT

By Dr. G. GORDON and Dr. M. G. M. JUKES

Laboratory of Physiology, University of Oxford

THE nucleus gracilis is the first synaptic region encountered by primary afferent fibres from the hinder half of the body in an important somæsthetic projection system. Earlier investigations in this Department[1,2] have shown that there is a marked functional differentiation along the rostro–caudal axis of this nucleus with respect to the cutaneous receptive fields of its cells, the presence or absence of afferent inhibition by cutaneous stimuli outside these receptive fields ('surround' inhibition), and the extent of rostrally directed (lemniscothalamic) projection. We can now amplify this earlier analysis and correlate it with the differential effects of stimulation of the cerebral cortex (contralateral area *SI*). External records were made by conventional methods from single cells in cats anæsthetized with sodium pentobarbitone.

We have continuously verified the observation of Gordon and Paine[1] (see also McComas's work on the rat[3]) that cells in the middle 3 mm of the long axis have a markedly smaller mean receptive field than those in the rostral 4 mm or those lying more caudal. We find this is true whether one considers cells specifically sensitive to bending hairs (*HS* cells) or cells sensitive to light touch or continuous pressure on the skin (*TP* cells) which are far less sensitive to bending hairs; though in each part of the long axis *TP* cells have a much larger mean receptive field than *HS* cells. This is also true if for each category of cells one considers separately those lying proximally and those lying distally on the hind-limb, the former having in each part of the nucleus larger mean receptive fields than the latter.

Cells showing afferent inhibition are common in the middle region of nucleus gracilis[1]. We have confirmed the observation of Perl *et al.*[4] that afferent inhibition is seen in *HS* cells but not in *TP* cells. We have found it in 95 per cent (of 50) *HS* cells tested in this part of the nucleus. It is also almost invariably found in cells sensitive to light brushing of the pads, and in cells responding to gentle pressure at the base of a claw. It can be demonstrated by various means; but the most sensitive method we have used is shown by Fig. 1*A* and *D*: this method

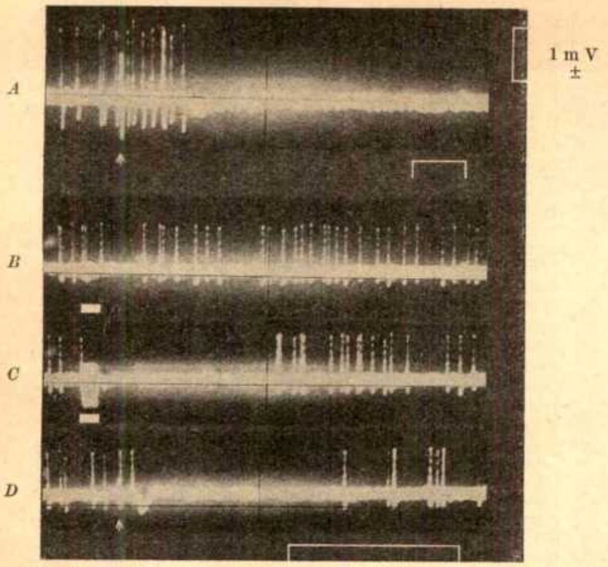

Fig. 1. *A*, inhibition of spontaneously discharging *HS* cell in middle region of the nucleus gracilis by electrical stimulus (single shock) applied to skin outside the receptive field. 25 sweeps, superimposed on storage oscilloscope. Arrow marks time of conditioning shock. Latency of complete inhibition 12 msec (note small negative wave at about this time from excitation of other cells by stimulus). Time calibration 10 msec.
B and *C*, inhibition of another *HS* cell in middle region of nucleus by brief train of shocks to contralateral cerebral cortex (*SI*), demonstrated by same method as in *A*. In *B* the stimulus is just at threshold strength: in *C* it is four times threshold. Timing and duration of cortical stimulus indicated by solid white bars. *D*, afferent inhibition in same cell as in *B* and *C*. Single shock applied to skin outside receptive field; timing shown by arrow. Time calibration for *B*, *C* and *D*, 100 msec. Voltage calibration applies to all records

can give an accurate measurement of its latency, which is of the same order as that for excitation of the cell from its receptive field, and of its duration, which increases with the strength of conditioning stimulus (up to several hundreds of msec).

Cells which do not show afferent inhibition can be shown to be facilitated by electrical stimuli outside their receptive fields (afferent facilitation). We have found this effect in all *TP* cells tested throughout the nucleus (confirming Perl *et al.*[4]), and also in those *HS* cells without afferent inhibition, most of which lay rostrally, where such inhibition is less common than in the middle region.

Electrical stimulation of the cortical sensorimotor area is known to excite or inhibit single cells in the nucleus gracilis[5-7]. We have found, on stimulation of the contralateral cortex (*SI* 'hind-limb area'), that excitation and inhibition are exerted selectively. Cortical inhibition, in the cells tested from the rostral and middle parts of the nucleus, was confined to cells (*HS* and 'pad' cells) showing afferent inhibition also (Fig. 1*B*, *C*, *D*). When elicited by a single cortical shock or brief train of shocks, latencies for inhibition in different cells ranged from 9 to 20 msec, the effect lasting up to about 100 msec, depending on strength of cortical stimulus. We have seen summation of effect between cortical and peripheral inhibitory actions, both of which may be presynaptic in nature[8]. Cortical excitation was seen only in cells in which afferent inhibition was absent, such of these cells as were tested showing afferent facilitation also. Latencies for excitation by a maximal cortical shock ranged from 5 to 10 msec (cf. ref. 7). All the *TP* cells tested, throughout the nucleus, were excited from the cortex (Fig. 2*A*). Cortical excitatory influences tend to dominate in the rostral part of the nucleus.

Antidromic excitation of cells by stimulating the contralateral medial lemniscus[2] shows that virtually all *HS* (and 'pad' and 'claw') cells with afferent inhibition project rostrally along this path. By contrast, only half the *TP* cells in the middle, and very few in the rostral part of the nucleus seem to project in this way; but lemniscal stimuli commonly cause 'trans-synaptic'[2] excitation of rostral *TP* cells, at a latency compatible with a path mediated by the thalamus and cortex (Fig. 2*B*). Some cells, not apparently projecting in the lemniscus, but excited by cortical stimulation, may be interneurones concerned in mediating cortical effects within the nucleus.

It is known that stimulation in the medial lemniscus can also cause inhibition of cells in the nucleus gracilis[1]: we have found this effect to be common, and easily elicited by brief trains of shocks to the contralateral but not to the ipsilateral lemniscus. It was observed in both *HS* and in *TP* cells. Such an effect may arise as a transcortical effect initiated through lemniscus and thalamus, but the latency of

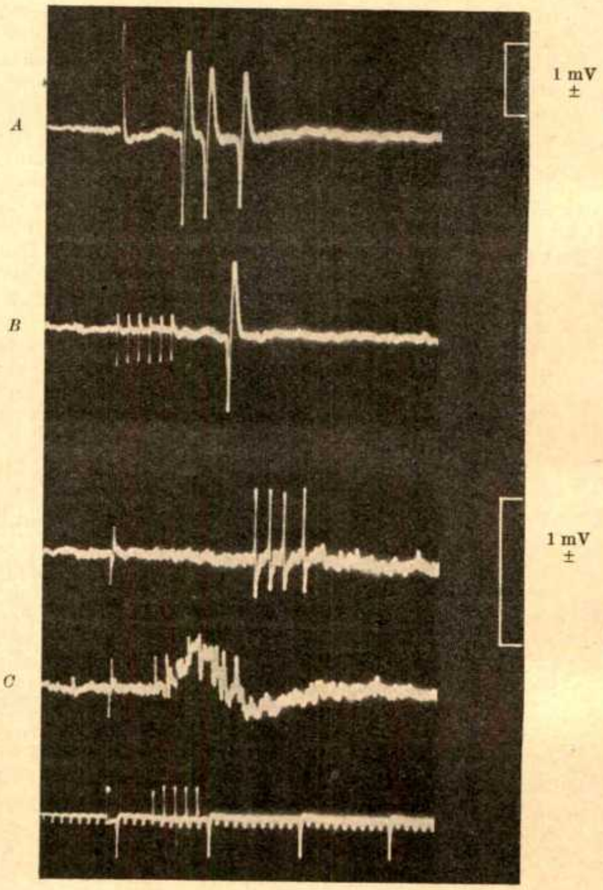

Fig. 2. *A*, excitation of typical *TP* cell in middle region of the nucleus gracilis by single shock to contralateral cerebral cortex (*SI*), of strength 10 times threshold to show minimal latency of response.
B, excitation of same cell as in *A* by brief train of shocks to contralateral medial lemniscus, of strength twice threshold to show minimal latency
C, inhibition of another *TP* cell (also excited from cortex) by brief train of shocks to contralateral medial lemniscus. Upper trace: control showing response to testing shock in skin receptive field. Lower trace: response to test shock totally inhibited by lemniscal stimulus, which itself evokes antidromic discharge in other cells. Onset of inhibition shown from other records to be 5 msec from beginning of lemniscal stimulus
Below, time calibration for all records, 1 and 10 msec; and stimulus marks for *C*. Timing of stimuli in *A* and *B* seen on sweeps. Upper voltage calibration refers to *A* and *B*, lower to *C*

the inhibition is commonly too short (as little as 5 msec) for such a path, and furthermore it is seen after wide excision of the sensorimotor cortex. It could arise through stimulation of aberrant corticofugal fibres passing through the lemniscus[9], though we have produced it by stimulation in the ventrobasal complex of the thalamus, where such fibres are not known. Its occurrence in *TP* cells which are excited from the cortex (Fig. 2*C*) renders either of these explanations unlikely for such cells, and again suggests the existence of a type of inhibition unconnected with the other inhibitory systems described: it is possibly a recurrent inhibition operated through axon collaterals (cf. the 'Renshaw system' of motoneurones) and initiated in our experiments by antidromic activation.

We consider that the close correlation which we find between cortical inhibition and 'surround' inhibition on one hand, and between cortical excitation and 'surround' facilitation on the other, suggests a general principle of some importance in the transmission of sensory information. While it is still unknown in what combinations or sequences these cortical influences are normally exerted, it appears from a consideration of such of these cells as project rostrally in the medial lemniscus, some excited and some inhibited by cortical activity, that such activity cannot be directed towards general suppression of sensory transmission at this level. Cortical modification must be selective when it occurs, one of its targets possibly being the level of spatial contrast achieved by the afferent inhibitory system.

CORRELATED ORIENTATION SOUNDS AND EAR MOVEMENTS OF HORSESHOE BATS

MOST of the bats which rely on echo-location have relatively large and complex external ears compared with those of other mammals. Some of the Microchiroptera, especially the family Vespertilionidae, hold their ears in a virtually fixed position relative to the head when they are active, while others move them in a variety of ways. One of the most striking of the various patterns of ear movements are those of the horseshoe bats (Rhinolophidae) described in considerable detail by Schneider and Möhres[1]. These bats also differ from those of other families in emitting their orientation sounds in the form of relatively long pulses which have a constant frequency for the greater part of their duration, followed by a downward frequency sweep at the end of each pulse[2]. Since sound travels through air at 34·4 cm/msec, a typical *Rhinolophus* pulse lasting 30 msec overlaps its own echo if the object is within about 5 m. In other Microchiroptera the orientation sounds are usually much shorter (0·3–10 msec). With a 1 msec pulse, overlaps occurs only at distances less than 17·2 cm.

Of the various types of ear movements adopted by the European greater horseshoe bat, *Rhinolophus ferrum-equinum*, the alternating ones associated with the scrutiny of objects at close range are of especial interest. As pointed out by Schneider and Möhres[1], when one of these bats is hanging quietly from a convenient toe-hold, the greatest activity of the external ears occurs when the bat is alert and is emitting numerous pulses of orientation sound. If a small object is slowly brought within 1–2 ft. of its head, the animal commonly begins rapid, alternating ear movements as it turns to face the approaching object. While the right ear is moving forward, the left pinna moves in the opposite direction, and the whole sequence is repeated so rapidly that it can only barely be seen even in good light.

Horseshoe bats, like other Microchiroptera so far examined, emit a 'buzz' of rapidly repeated and shortened orientation sounds when echo-locating objects at close range. Direct observation suggested that the rapidly alternating ear movements were closely correlated with the buzz. But the short pulses are emitted at repetition-rates up to 50 or more per sec, though only for a small fraction of a sec at a time, and the unaided eye cannot determine just how closely pulses and ear movements are correlated. Although Schneider and Möhres[1] report that the alternating, out-of-phase ear movements in the greater horseshoe bat have a maximum frequency of 5–6 c/sec, our preliminary observations suggested much more rapid movements. We have therefore taken motion pictures and synchronized tape-recordings of this species, some at 768 frames/sec by techniques described elsewhere[3] and others at 64 frames/sec with conventional equipment. Several cases of ear alternation were selected on the basis of photographic clarity. These appear to be typical of the majority of instances in which the bat is hanging from a toe-hold that allows a free 'view' below and horizontally and in which its interest was aroused by a small stick or forceps moved slowly to 30–50 cm below its head. Under these conditions the buzzes consisted of 6–10 pulses, each of which was 9·5–22 msec long, at repetition-rates of 28–88 pulses/sec.

There was indeed a close, though not perfect, correlation between the emission of the short pulses and the alternating movements of the ears. It was our distinct impression that the closest correlation occurred when the bat was most interested in the stick or forceps. The most closely correlated of the three cases photographed at 768 frames/sec was used to prepare the graphic comparison of ear movements and orientation sounds shown in Fig. 1. The time of arrival of the orientation sound waves at the microphone is plotted above the corresponding ear movements. Since the microphone was roughly twice as far from the bat as the forceps on which its attention appeared to be concentrated, the upper part of Fig. 1 shows the time when echo waves from

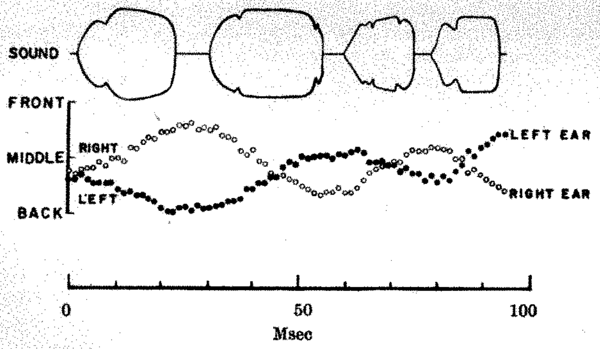

Fig. 1. Correlation between ear position and time of arrival of orientation of sound waves. Ear position was measured from a reference point on the bat to the tip of the ear for each frame in this part of the sequence. This is a detail of Fig. 2*a* and shows the approximately sinusoidal nature of the ear movements

the forceps reached the bat's ears, subject to an uncertainty of about 1 msec. It is clear from Fig. 1 that, in this case, the ears were being moved almost synchronously with the orientation sounds. In other cases, however, the ear movements and sound patterns were not so closely correlated. In Fig. 2 the whole of three sequences is plotted in less detail. As can be judged from the scatter of the points in Fig. 1, there was enough uncertainty in the frame-by-frame measurements from the 16-mm film that only the main outline of the ear movements could be determined. Nevertheless, Fig. 2 shows typical examples of shifting phase relations between extremes of ear position and sound emission.

A few additional high-speed motion pictures showed a *Rhinolophus* while landing. One of these involved a buzz consisting of 11 pulses in 152 msec, and in two others, bursts of 15 pulses in 205 msec, corresponding to pulse repetition rates of 72 and 73 pulses/sec, respectively. In one of the three cases the ears were visible in the motion pictures for part of the buzz during which there was a 1 : 1 correlation between pulses and ear movements similar to that shown in Fig. 1. The pulses in the buzzes which accompanied landing manœuvres were very similar to those recorded when a horseshoe bat flies close to small vertical strings[2]. These 'landing buzzes' occurred when the bat was within 10 cm of its landing place, so that there must have been almost total overlap between the emitted pulse and the echo from the surface on which the bat was about to land.

Under other conditions, including flight through relatively unencumbered rooms, the orientation sounds are as long as 70 msec, have relatively low repetition-rates, and may occur independently of the ear movements, which are much slower. It is probably of considerable significance that, when a horseshoe bat has the greatest need for accurate information about some object at close range, it uses its shortest duration pulses and emits each of these while one ear is moving forward and the other backward.

The importance of these ear movements to the bat is indicated by their consistency and by Schneider and Möhres's discovery that if horseshoe bats are deprived of the use of the muscles that move the pinnae relative to the head, they compensate by nodding the head vigorously. A variety of hypotheses can be advanced to explain how ear movements might facilitate echo-location. Pye[4] has proposed one such theory, and a number of others are suggested by analogy to various radar systems. But we have no information about the physical acoustics of the external ear of *Rhinolophus* at rest or in motion, or its sensitivity to sounds arriving from various directions. Neurophysiological studies on bats of the family Rhinolophidae might well be as informative as those on the Vespertilionidae by Grinnell[5]. In the absence of such information for the horseshoe bats, it seems to us unprofitable to speculate in this communication about the precise function of these pulse-correlated ear movements.

We thank Dr. W. H. Thorpe for making it possible for one of us (D. R. G.) to examine these bats at the Madingley Field Station of the Department of Zoology, University of Cambridge. We also thank Roger Ransome and other zoologists who helped us obtain the horseshoe bats. Financial support was provided by a contract between the Office of Naval Research and Harvard University.

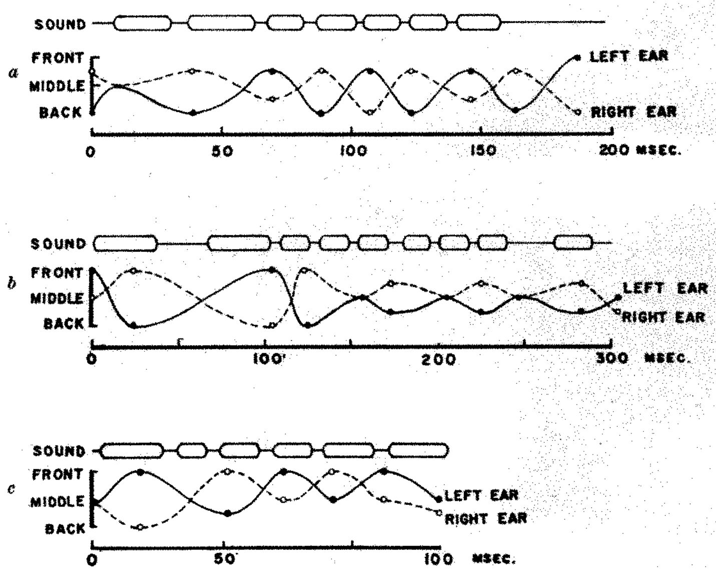

Fig. 2. Arrival time of orientation pulses relative to extremes of ear movement. Ear position was estimated relative to the head of the bat. Case *b* shows a common type of buzz consisting of an initial long pulse followed by a series of shorter ones

VERY rapid alternating movements of the two ears of *Rhinolophus ferrum-equinum* were first described by Möhres[1], and the importance of these movements to echo-location was demonstrated by Schneider and Möhres[2]. Recently, Griffin *et al.* (preceding communication) have shown that in general each echo-location sound-pulse is accompanied by a forward movement of one ear and a backward one of the other; that is, complete cycles of ear movement occur at half the pulse repetition-rate. This relation may easily be observed by eye in bats which are awake but inactive and producing pulses at very low rates. Observations at higher rates in active bats have been made from high-speed film and by other methods which have yielded similar results to those of Griffin *et al.*

The rate of ear movement in flight was measured from a ciné film kindly made available by the Granada Television–Zoological Society Film Unit at the London Zoo. The film (taken at 1,000–1,500 frames/sec with a 10 msec time-marker along one edge) showed greater horseshoe bats taking off and flying in to land. Rapid alternating movements of the two ears were clearly demonstrated and in several sequences could easily be measured. The time taken for a pair of forward and backward movements (one cycle) by each ear varied from 1/16 sec to 1/25 sec, with one instance of 1/28 sec. Peak-to-peak amplitudes for the tip of the ear often appeared to exceed 1 cm but the movements also involved variable complex turning components and changes in shape of the pinna, as well as movements of the head. No sequence was long enough to follow more than a few cycles of movement and no information about the bat's sounds was available.

In subsequent laboratory experiments ear movement was measured by an acoustic Doppler echo-location system operating at 95 kc/s. Echoes were amplified by a radio receiver, heterodyned to zero centre-frequency and recorded on magnetic tape or by an oscilloscope and camera. The transmitter and receiver were masked by paper tubes, convergent at their open ends, in order to limit the records to one ear at a time. In some experiments the echoes were heterodyned to 5 kc/s for subsequent examination with a sound-spectrum analyser which distinguished between forward and backward movements. Orientation sounds produced by the bat, at 84 kc/s, were heterodyned by a second radio receiver to 1 kc/s and recorded on a second channel of the oscilloscope or tape-recorder. The two ultrasonic microphones were placed so that the timing error between channels was under 1 msec and no cross-talk was experienced.

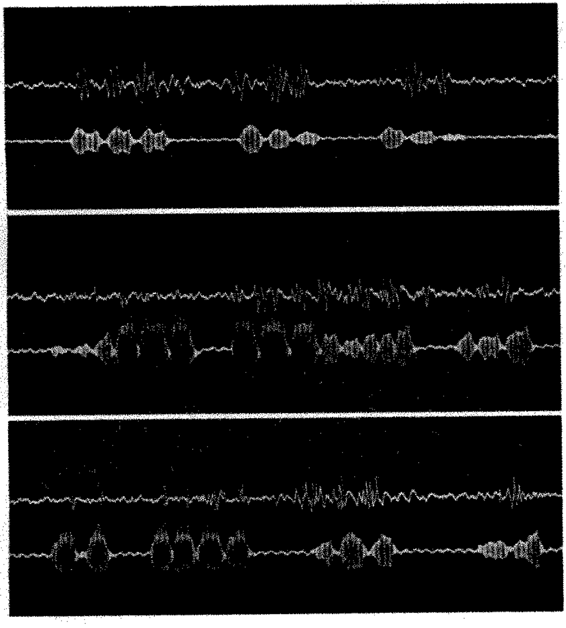

Fig. 3. Three samples from recordings of ear movements and echo-location pulses of *Rhinolophus ferrumequinum* (reading from left to right). Upper traces, the output from the Doppler movement detector; lower traces, the bat's pulses with a time-marking ripple of 100 c/s. Amplitude changes in both traces are caused by the bat turning its head

This method permits long continuous recordings (Fig. 3) the evaluation of which is extremely simple. The velocity and amplitude of the ear movement are given respectively by the frequency and the number of cycles of the output of the Doppler system. Amplitudes measured in this way agree closely with those obtained from the ciné film. Amplitude of the Doppler output is only related to the intensity of echoes received from the ear.

The bats were held in the hand. They vigorously investigated their surroundings or objects brought into their vicinity and always gave particularly strong responses to nearby movements. They were not disturbed by the Doppler sensing signal and always appeared to ignore it. Under these conditions the animals emitted probing pulses in discrete groups at a steady rate of 6·0–8·3 groups/sec which seemed to correspond to the respiration-rate. In familiar surroundings each group contained only two pulses, each of 30–50 msec duration, or a single pulse of 40–60 msec. In unfamiliar conditions or when a new object was presented for inspection, as many as seven or eight pulses were produced in each group, the pulse length reducing to as little as 10 msec and the 'instantaneous rate' rising to 60–80 pulses/sec.

Activity of the pinna was always associated with the emission of pulse groups, as may be clearly demonstrated by replaying the tape-recordings at reduced speed into an oscilloscope or loudspeaker. Correlation between individual movements and pulses was somewhat variable as found by Griffin *et al.* Numerical correspondence was generally good and was seldom much in error even at pulse-rates greater than 50/sec (25 cycles of movement/sec). But at all speeds the temporal relation between sound and movement varied rapidly. The greatest velocity may be reached at any time from the beginning to the end of a pulse or even a little outside it. Whether this is functionally significant or demonstrates imperfect control by the bat cannot be decided until the role of the movements in echo-location is established.

A brief investigation of the muscles responsible for ear movements was undertaken. A fine concentric electromyograph electrode, made from a No. 30 hypodermic needle (300μ outside diameter), was used to explore the scalp of an active bat. The presence of this electrode often suppressed ear movements but some recordings were obtained. Short bursts of potential spikes, having a relation to ultrasound pulses similar to that of the ear movements, were recorded from the region of the superficial cervico-auricularis muscle[2] and were believed to originate in that muscle. Simultaneous recording of muscle potentials and Doppler echoes was not attempted.

The speed of contraction of the superficial cervico-auricularis muscle when loaded with the pinna was tested by direct electrical stimulation. The bats were deeply anæsthetized with 'Nembutal' in alcohol and were warmed to a constant rectal temperature of 37° C. The scalp was reflected on one side to expose the muscle, which was stimulated by negative 1-msec square-waves through a Ringer-wick electrode. Movement was observed by eye and by attaching the pinna to a light-weight liquid potentiometer for oscilloscope display. Tetanic summation was absent at all rates of stimulation up to 25/sec but developed progressively above 30/sec. There was still a considerable amplitude of vibratory ear movement at 70/sec and the alternating component disappeared completely at about 100/sec. The gastrocnemius muscle of a laboratory mouse was nearly as fast as this, but only when its normal load was removed by severing the tendon. This shows that the auricular muscles are capable of moving the pinna by separate contractions within the normal speed range of the active bat.

Further work is needed to decide the function of these remarkable movements. Little is known of their finer detail and nothing of their nervous control. However, the present results are compatible with the hypothesis[3] that *Rhinolophus* is able to use the Doppler shifts which the moving ears impose on returning echoes of its own orientation sounds.

RESPONSES TO SOUND IN PYRALID MOTHS

By P. BELTON

Entomology Research Institute for Biological Control, Research Branch,
Canada Department of Agriculture, Belleville, Ontario

SOUNDS of high audible or ultrasonic frequency have been shown to affect the flight patterns of certain grass-dwelling pyralid moths[1]. In laboratory experiments the pyralid species *Anagasta kuehniella* (Zell.), a flour moth; *Ostrinia nubilalis* (Hbn.), the European corn borer, and *Galleria mellonella* (L.), the wax moth, were affected by the same type of sounds. The behavioural responses are variable: tethered moths may stop flying or start to fly; moths at rest may move their antennæ or wings in a particular way each time they are stimulated or they may show no overt response; immobilized moths often contract their abdominal musculature in such a way as to protrude the tympanal organs, which are situated on the ventral surface of the first abdominal segment. Because of the economic importance of members of this group of moths, an investigation of any factors that affect their behaviour is desirable. The tympanal organs of pyralid moths are anatomically distinct from those of other groups of Lepidoptera, which may indicate that they evolved independently[2], so that the comparative aspects of the investigation are also of interest.

Moths were decapitated and immobilized, ventral side upward, on a cork platform. Electrical activity was recorded differentially between a glass-capillary microelectrode and a steel microelectrode placed on either side of the tympanal nerve; the tip of the abdomen was earthed through electrode jelly. Signals were fed into a condenser-coupled amplifier and displayed on an oscilloscope.

Electrical responses were recorded from *O. nubilalis* and *G. mellonella*. Fig. 1 shows examples of the nerve impulses recorded from one specimen of *O. nubilalis* in response to clicks, a Galton whistle with its main

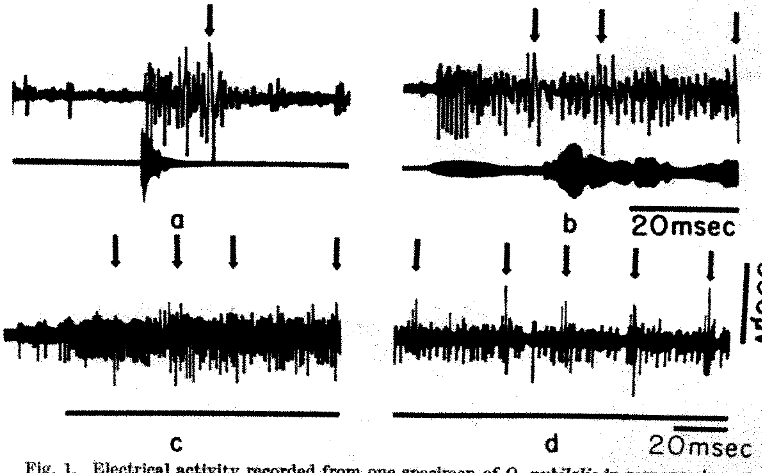

Fig. 1. Electrical activity recorded from one specimen of *O. nubilalis* in response to *a*, a click produced by two coins; *b*, a Galton whistle with its main output at 22 kc/s; *c* and *d*, a pure tone with a frequency of 32 kc/s. The lower trace in *a* and *b* is the response of a condenser microphone near the preparation; the horizontal line in *c* and *d* indicates the duration of the stimulus. The arrows indicate responses of nearby muscle fibres that are distorted by the recording system. The amplitude of the nerve impulses is indicated by the vertical calibration line

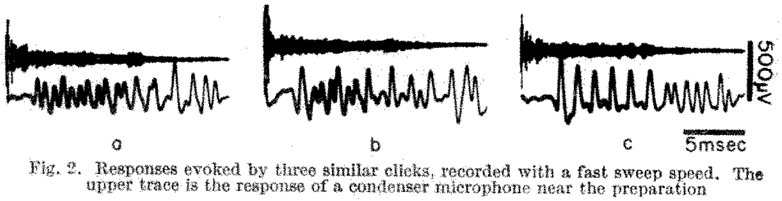

Fig. 2. Responses evoked by three similar clicks, recorded with a fast sweep speed. The upper trace is the response of a condenser microphone near the preparation

output at 22 kc/s and a sine wave with a frequency of 32 kc/s delivered by a condenser transducer, respectively.

The four successful preparations of *O. nubilalis* showed an irregular resting discharge in the nerve, although experiments were conducted in a sound-proof room, in which the ambient sound-level was reduced by about 60 db. When the electrical activity was made audible it became clear that the resting discharge was reduced in frequency immediately after stimulation so that it seemed probable that the discharge was indeed produced by acoustically sensitive cells. The tympanal organs of *O. nubilalis* and *G. mellonella* responded to sound-levels of about 30 db (with reference to a sound pressure of 0·0002 dyne cm^{-2}) generated by the whistle and also responded to the sound produced by clicking two coins together 30–40 ft. away from the moth (a peak sound-level of approximately 40 db at the preparation).

The frequency of nerve impulses in response to a continuous tone is reduced with time. This can be seen in Figs. 1*c* and *d*, which show the response at the onset (Fig. 1*c*) and after 5 sec (Fig. 1*d*) of stimulation. The frequency of responses greater than 50 μV in amplitude dropped from 990/sec during the first 100 msec to 480/sec in the same time, after 5 sec. The preparations did not respond to pure tones below 18 kc/s at the largest sound pressures that could be generated (a sound-level of about 90 db). Preparations did respond to the Galton whistle when it was set at a frequency of 8 kc/s, perhaps because of the harmonic content of the sound it produced. At this setting, 15 per cent of the output of the whistle consisted of second and third harmonic distortion.

The response of preparations made from *O. nubilalis* to the click produced by coins is shown with a faster sweep in Fig. 2. It is apparent from these records that at least two sensilla were responding to the sound. Although the sensilla are connected to the same region of the tympanum and are enclosed in the same capsule of connective tissue, the two sets of responses were independent. The two units that can be distinguished clearly fire alternately in Fig. 2*a* and in varying degrees of synchronization in Fig. 2*b* and *c*. If the six large responses of Fig. 2*c* represent two units firing synchronously, there then appears to be a third acoustic unit with a small response firing alternately with the two larger units; this is consistent with the results of histological investigation[3] that demonstrated the presence of four chordotonal sensilla in the tympanal organ.

The sensitivity of the pyralid organs to high audible or ultrasonic frequencies is about the same as that of the corresponding organs of noctuid moths which have been investigated by Roeder and Treat[4]. The latency of the repsonse to clicks is also similar (3·5–4 msec), and initial synchronous firing of two fibres was observed in the tympanal nerves of both groups (compare Fig. 1*b* with Fig. 3*c* of Roeder and Treat[4]). The chordotonal sensilla of all the tympanal organs which have been investigated share one important property: the responses which they generate in the auditory nerve fibres are independent of one another and bear no clear relation to the frequency of the sound. This is almost certainly related to the fact that the nerve fibres they supply are unable to conduct impulses at rates higher than a few thousand per sec. Differences in physiological mechanism must exist between this type of sensillum and, for example, the chordotonal sensilla of the mosquito antenna that generate nerve impulses in strict relationship with the low-frequency sound stimulus[5].

The large responses that were observed in the tympanal nerve of pyralid moths showed adaptation in response to a continuous tone. However, this was not so rapid as the adaptation observed in noctuid, or in arctiid and notodontid moths[4,6]. There is evidence of a non-acoustic sensillum associated with the tympanal organ in those three groups, but no electrical evidence for the presence of such a cell was obtained in any of the preparations made from pyralid moths.

Perhaps the most striking feature of the pyralid tympanal organ is that it is apparently insensitive to range of audible frequencies between about 2 and 18 kc/s, which can be detected by the tympanal organs of other insects that have been examined.

There is now a good deal of evidence in support of the hypothesis that the tympanal organs of Lepidoptera are of use in the detection of echo-sounding bats. It appears that the tympanal organs of pyralid moths could also have this function.

The experiments described here led up to a field test in the summer of 1962 to determine whether sounds would influence the behaviour of *O. nubilalis* to such an extent that some reduction of their natural population in cultivated maize could be obtained. A sound resembling that produced by a single bat was broadcast over experimental plots from mid-June until the maize was mature. The sound reduced the number of larvæ in the stems and ears of about 1,000 plants by between 50 and 60 per cent.

CELLULAR DIFFERENTIATION IN STALKED BACTERIA

By J. L. STOVE and R. Y. STANIER

Department of Bacteriology, University of California, Berkeley

THE genus *Caulobacter* was created in 1935 by Henrici and Johnson[1] to accommodate a distinctive, but previously unrecognized, group of stalked unicellular bacteria. Henrici and Johnson encountered these organisms in the course of their studies on fresh-water bacteria which were conducted by the slide culture technique[2]. When slides are immersed in water for a week or two, the stalked cells of *Caulobacter* adhere to the glass and can be readily recognized on microscopic examination. Although Henrici and Johnson did not cultivate these bacteria, one representative of the group had been isolated as early as 1905[3], and later workers[4-6] have obtained three additional strains in pure culture. The isolation and maintenance of these bacteria is in fact simple; they are strict aerobes, and grow readily on a dilute peptone-yeast extract medium. From water samples and other natural sources we have obtained about forty strains in pure culture and are now conducting a systematic study of the group. The developmental cycle which is characteristic of *Caulobacter* has been elucidated in the course of this work.

Two different kinds of cells occur in any *Caulobacter* culture: swarmer cells and stalked cells. Both types are small rods of similar shape and dimensions; in some strains the cells are straight, in others distinctly curved. The swarmer bears a single polar flagellum and is grossly indistinguishable from a simple unicellular bacterium of the *Pseudomonas* or *Vibrio* type, except for the presence of a secreted substance occasionally observable at the base of the flagellum. This substance confers on the cell the property of adhesiveness to solid objects and will be referred to as the holdfast material.

The second type of cell bears a stalk at one pole in in place of a flagellum and is, therefore, not motile. The stalk is much thinner than the cell and can barely be resolved by the light microscope; the interpretation of its structure and relation to the cell became possible only as a result of observations with the electron microscope. As shown by Houwink[4,5,7], the stalk is not a secreted structure, but an outgrowth of the cell itself; its tubular wall is continuous with the cell wall, and encloses a very thin cytoplasmic core, continuous with the cytoplasmic region of the cell. The only secreted element is the holdfast material which, after the stalk has developed, is present at the distal end of the stalk.

Cells often occur in rosettes which adhere to one another by means of a common mass of holdfast material. Both types of cell and a rosette are shown in Fig. 1.

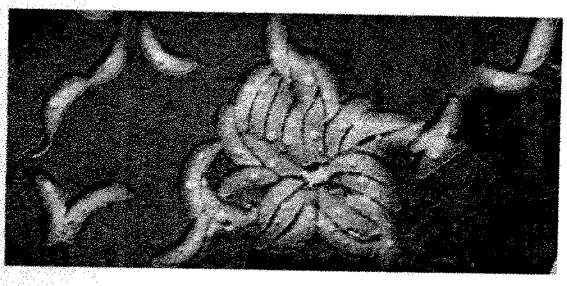

Fig. 1. Swarmers, a dividing stalked cell and a rosette of *Caulobacter*. Electron micrograph, shadowed with uranium

As shown by several workers[1,4,5,7], a division of a stalked cell gives rise to two unlike sister cells: a basal stalked cell and an apical swarmer. Existing accounts imply that the swarmer undergoes the transition to a stalked cell as a consequence of attachment to a solid substrate; according to this interpretation, stalk formation is a facultative event in the life-cycle, conditioned by environmental factors. We have found that this is not the case; on the contrary, stalk formation is an obligatory stage in the development of every swarmer, attached or unattached, and always precedes the first division of the swarmer.

The two kinds of cells in a culture of *Caulobacter* can be physically separated from one another by centrifugation. Swarmers will form a well-packed pellet in a centrifugal field in which stalked cells sediment as a looser, supernatant layer, apparently because the stalks prevent close packing. Consequently, it is possible to prepare almost homogeneous suspensions of each cell type, and to study their subsequent growth. In a liquid culture inoculated with swarmers, nearly all the members of the population develop stalks before there is any increase in viable count; the population then doubles within a period that is shorter than the mean generation time of swarmer cells, and during this doubling the percentage of cells which have stalks falls to about half its preceding maximal value (Fig. 2). In a liquid culture inoculated with stalked cells, the first division occurs significantly earlier than in a culture inoculated with swarmers.

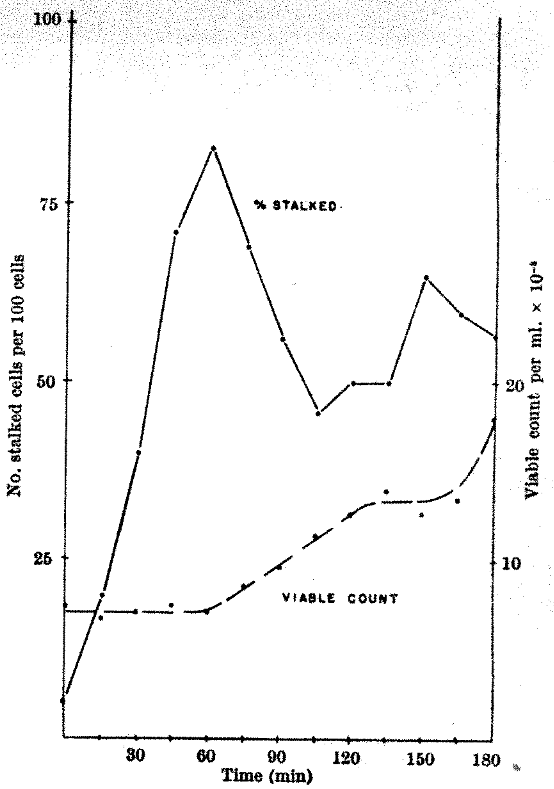

Fig. 2. Stalk development and cell division in an agitated culture inoculated with swarmer cells

We have also followed the growth-cycle by continuous microscopic observations on single clones in microcultures. When a stalked cell divides, giving rise to two unlike sister cells, division of the stalked sibling always precedes division of the swarmer sibling. However, after the swarmer has formed a stalk and divided once, its subsequent division times

Table 1. DIVISION TIMES OF SWARMER AND STALKED CELLS AS DETERMINED BY DIRECT OBSERVATION OF MICROCULTURES

Clone number	Total number of divisions observed	Average division time (min) Swarmer cells	Stalked cells
A	18	115 (7)	90 (11)
B	11	128 (4)	96 (7)
C	9	109 (3)	97 (6)
D	11	124 (4)	91 (7)
E	9	124 (3)	90 (6)
F	12	120 (5)	95 (7)

Cells were inoculated into the microculture and observed continuously for several hours. In this experiment, one field was observed and each cell mapped; in this way, several individual clones could be observed under identical conditions. Observation was terminated when the field became too crowded for accurate tracking of each cell's progeny. The number of observations of each type of division is given parenthetically after the average division time.

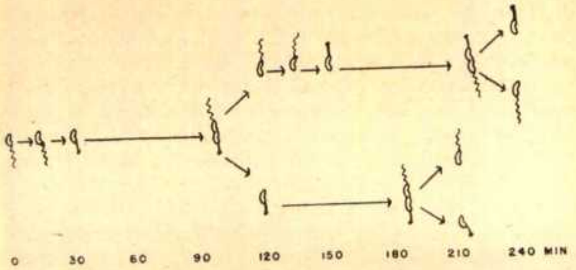

Fig. 3. Stalk development and cell division within a clone

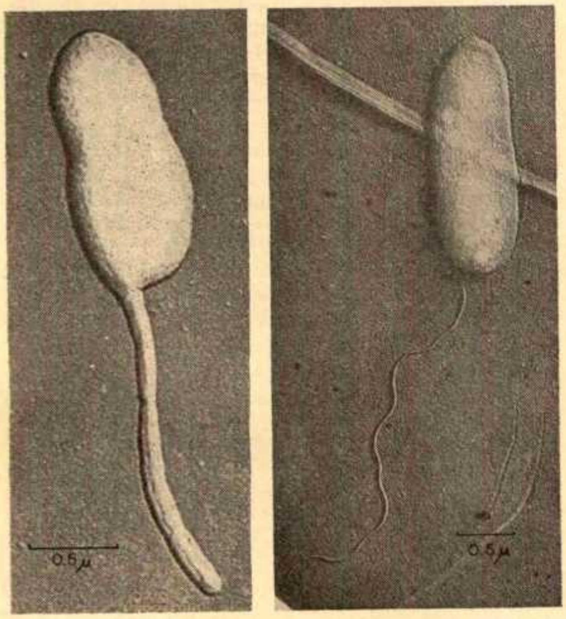

Fig. 4. Swarmer cell and stalked cell showing excentral location of flagellum and stalk in this strain. Electron micrograph, shadowed with uranium

are comparable with those of its original stalked sibling. Some typical data are shown in Table 1, and represented diagrammatically in Fig. 3. In effect, the difference between the division time of a swarmer and of a stalked cell represents the time required for the growth of the stalk. In the particular strain that we have used for detailed studies, it can be calculated that stalk formation takes 25–30 min under conditions where the division of a stalked cell requires 90–95 min.

The observations described here show that the capacity for stalk formation is a genetic property of the swarmer cell that is invariably expressed during its development. A single swarmer cell can develop only one stalk; and the stalk, like the flagellum, always arises at one pole of the cell. Although mature stalked cells are typically non-motile and devoid of flagella, the flagellum persists for a short time during the outgrowth of the stalk. As first observed by Houwink[7], the flagellum is attached to the distal end of the developing stalk; clearly, therefore, outgrowth of the stalk proceeds from the flagellated pole of the cell.

In most strains, both flagellum and stalk arise centrally at the pole of the cell. However, some of the strains in our collection are characterized by stalks which arise excentrally from the cell apex; in such strains, electron micrographs show that the flagellum is likewise attached excentrally to the cell (Fig. 4). One may, therefore, suppose that the cytoplasmic determinant of stalk formation is very closely related to the basal granule of the flagellum, and perhaps identical with it. This interpretation of the relationship between flagellum and stalk is distinctly different from that offered by Zavarzin[8], who contends that the flagellum becomes 'ensheathed' and is thus converted into the structure recognized as a stalk.

If the hypothesis that the determinants of flagellum and stalk are related is correct, the capacity for stalk formation might be lost as a consequence of a mutation which abolished the capacity for the formation of a flagellum. It is possible to recognize bacterial mutants in which flagellar function has been lost, since they form compact colonies in semi-solid agar, whereas colonies arising from motile cells are more diffuse[9]. Using this technique, we have isolated a series of non-motile *Caulobacter* mutants from ultraviolet irradiated populations. In one class of mutants, the swarmer cells have short flagellar stumps demonstrable by electron microscopy, and must consequently have retained the basal granule. A second class forms no flagella. All mutants so far obtained exhibit normal stalk formation, which shows that the mechanism of stalk formation proposed by Zavarzin cannot be correct. These observations do not support the postulate that the determinants for the formation of flagellum and stalk are closely related. However, they do not exclude it, since loss or alteration of the flagellum does not necessarily reflect a loss of the cytoplasmic components of the flagellar apparatus. Despite the failure of this test, the attempt to isolate stalkless mutants through indirect selection on the basis of immotility appears to merit further exploration.

In addition to its capacity for stalk development, the flagellated pole of a *Caulobacter* swarmer has another specific property: adhesiveness. By virtue of this property, the swarmer can undergo polarized attachment to a variety of solid objects: glass, cellu-

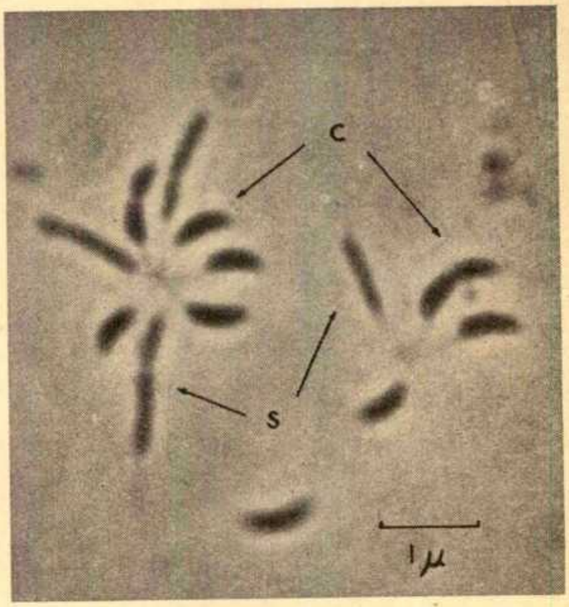

Fig. 5. Rosettes comprised of cells of two different morphological types of *Caulobacter*. *C*, curved; *S*, straight. Phase-contrast photomicrograph

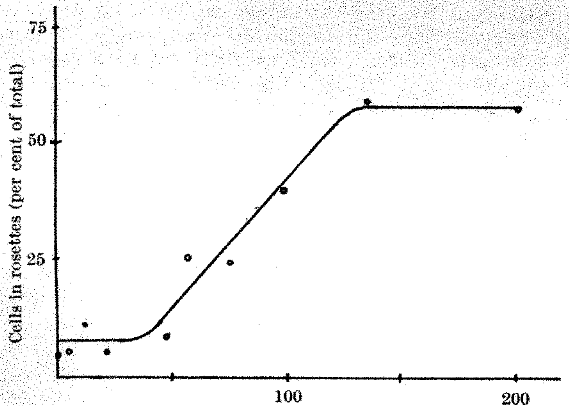

Fig. 6. Relation between initial turbidity and rosette formation, measured after 2 h incubation of agitated cultures of swarmer cells

lose fibres, other *Caulobacter* cells, and the cells of other micro-organisms[4,6,7,10,11]. Owing to the identical site of flagellum and stalk formation, development of the stalk takes place at the adherent pole of the cell. However, adhesion is not necessary for stalk formation; a cell which fails to make an effective contact as a swarmer proceeds to normal development in the unattached state. In an agitated culture where the population density is low, most cells develop stalks in the unattached state.

In a dense suspension of *Caulobacter* swarmers, the most common type of effective contact is contact with another swarmer. To be effective, however, such contact must be made between flagellated poles: a swarmer cannot adhere to any other portion of the cell surface of another swarmer, and has not been seen to adhere to a stalked cell. As a consequence of these restrictions, effective collisions result in the formation of clusters of swarmers, attached to one another by the flagellated poles. The subsequent development of stalks by the cells in such clusters gives rise to the rosettes which are such a characteristic feature of these organisms in pure culture. Polar adhesion is not a strain-specific character, as shown by the fact that when swarmers of two structurally distinguishable strains are mixed at high density, mixed rosettes develop (Fig. 5).

Adhesion of the swarmers is not initiated at 4° C, and, therefore, suspensions of isolated swarmers can be prepared at any desired density by differential centrifugation of chilled cultures and resuspension of the swarmers in a pre-chilled medium. When such a suspension is warmed to room temperature, clusters of swarmers are formed within a few minutes, provided that the cell density is high. The fraction of the swarmers that adhere to one another and thereby give rise to rosettes is proportional to the initial density of the suspension (Fig. 6).

These findings show that the swarmer cell of *Caulobacter*, although grossly indistinguishable from the vegetative cell of a typical pseudomonad, is endowed with a unique potentiality for differentiation. The flagellated pole of a *Caulobacter* cell has two specific properties—adhesiveness, and capacity to develop a stalk—which are not possessed by the flagellated pole of a *Pseudomonas* or *Vibrio*.

METHOD OF PREPARING HISTAMINE SENSITIZING FACTOR

By Dr. J. MUNOZ and B. M. HESTEKIN

National Institute of Allergy and Infectious Diseases, U.S. National Institutes of Health,
Rocky Mountain Laboratory, Hamilton, Montana

BORDETELLA pertussis contains a substance capable of sensitizing mice to histamine[1,2]. Most workers who have examined this histamine sensitization phenomenon have used whole, killed *B. pertussis* cells[1–4], some have used cell-free culture supernatants or extracts from these organisms[5–8], and recently Niwa[9] has published a method of purifying the histamine sensitizing factor from culture supernatants. It has been shown[10,11] that cell wall preparations contain most of the histamine sensitizing factor activity when cells are collected before lysis occurs. In this preliminary report a simple method is described for preparing histamine sensitizing factor from whole bacterial cells grown in liquid medium.

Procedures and results. *B. pertussis* cells grown in liquid medium[12] were collected by centrifugation, re-suspended in saline to a concentration of 1,000 billion cells per ml. and extracted twice with 3 volumes of acetone at room temperature. (The cells were kindly supplied to us through the courtesy of Dr. Lee F. Schuchardt of Merck, Sharp and Dohme, Inc., West Point, Pennsylvania.) The cells were dried by applying suction through the cell paste contained in a Buchner funnel and then stored at 2°–5° C in a firmly stoppered bottle. From these acetone-dried cells histamine sensitizing factor was extracted in the following manner: 15 g of cells were added to 500 ml. of saline and thoroughly re-suspended by means of a tissue homogenizer. The cells were disrupted in the pressure cell of Ribi *et al.*[13] at 40,000 lb./in.^{2}. Cold nitrogen gas was used instead of carbon dioxide to prevent the cell paste from heating during this procedure. An additional 500 ml. of saline were added to the disrupted cells and then the *p*H was adjusted to 8·5 with 1 N sodium hydroxide. The suspension was kept cold and stirred constantly during addition of base and for 1–2 h thereafter. The suspension was centrifuged at 13,000 r.p.m. (27,000*g*) in a Servall refrigerated centrifuge and the clear, amber-coloured supernatant was decanted and its *p*H adjusted to 7·4 with 0·1 N hydrochloric acid. The sediment was re-suspended in saline. Both supernatant and sediment were dialysed for 4 days against 4 eight-litre changes of cold distilled water and then lyophilized. Most of the histamine sensitizing factor activity was found in the supernatant (Table 1). The activity of dried saline extract was found to be about 10–30μ per mouse. The saline extract contains various antigens as shown by agar diffusion studies with hyper-immune *B. pertussis* antiserum. At least three distinct bands were obtained in Ouchterlony diffusion tests with a hyper-immune rabbit serum. The acid-precipitated saline extract contained 14·6 per cent nitrogen, 4·5 per cent hexose, 1·8 per cent phosphorus, 28·4 per cent fatty acid esters + fatty acid amides and 0·4 per cent hexosamine.

Table 1. HISTAMINE SENSITIZING ACTIVITY OF *B. pertussis* EXTRACTS

Preparation	Dose per mouse 90 μg	30 μg	10 μg
Whole cells	8/17*	8/20	4/20
Acetone dried cells	9/20	9/20	1/20
Saline extracted cells	12/20	3/20	3/20
Saline extract	15/20	18/20	3/20
Untreated controls		0/18	

$*\ \dfrac{\text{No. of mice dying}}{\text{Total No. of mice tested}}$

Various methods have been used in an effort to purify the histamine sensitizing factor further. The most promising technique so far has been that of starch-block electrophoresis[14]. With lyophilized saline extract as starting material, the following procedure has been used with some success.

A starch block (potato purified starch, J. T. Baker Chemical Co.) was prepared in phosphate buffer (*p*H 7·2 and 0·024 ionic strength). 70 mg of saline extract were dissolved in 4·0 ml. of buffer and 3·5 ml. of this solution were mixed with 4 g of dry starch and placed in a 1 × 6 × 1-cm well cut out in the starch block. Electrophoresis was carried out in the cold (2°–5° C) for 21 h at 8–10 m.amp and 400 V. At the end of the run the starch block was cut into 2-cm pieces and each was extracted with 15 ml. phosphate buffer. The extract from each fraction was analysed for tyrosine by the Folin–Ciocalteau method and for histamine sensitizing factor activity in mice. The tyrosine peaks obtained (Fig. 1) indicate that saline extract contained at least 6 substances and that the histamine sensitizing factor (Fig. 2) is found in a fraction which moves slowly towards the cathode at the *p*H used. This material gives a typical nucleic acid absorption in the Beckman *DU* spectrophotometer probably due to contamination with a substance which moves just ahead of the histamine sensitizing factor and has a strong nucleic acid or nucleoprotein absorption. Investigations are now being carried out to establish the exact chemical nature of histamine sensitizing factor, as well as its role on protection of mice to infection with *B. pertussis*.

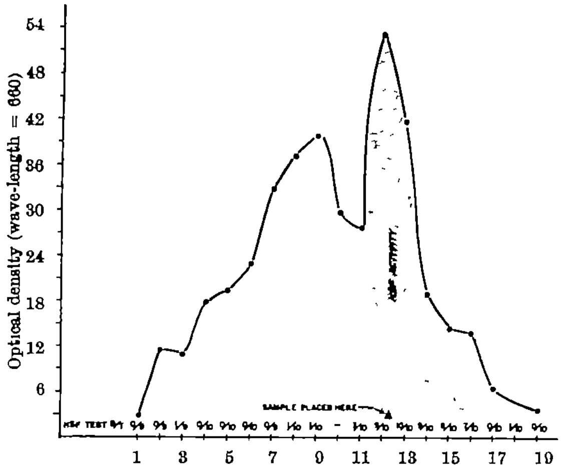

Fig. 1. Each starch block fraction was tested for the presence of tyrosine with Folin–Ciocalteau reagent and for its capacity to sensitize mice to histamine. The results of the mouse test at the bottom of graph are given as number of deaths over total number of mice tested

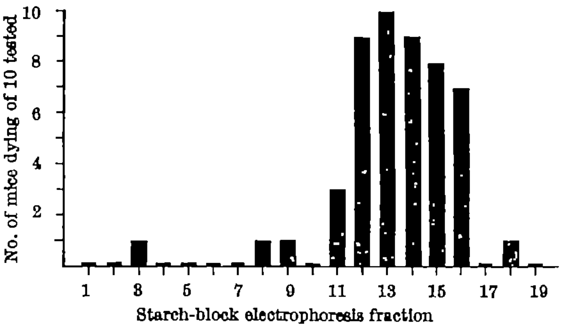

Fig. 2. Histamine sensitizing factor activity of individual fractions from starch-block electrophoresis

As found by Niwa[9], histamine sensitizing factor is more soluble at a *p*H higher than 7. Histamine sensitizing factor activity can be completely precipitated out of solutions at *p*H 4·8 and, as found previously with whole cells by Kind[2] and in extracts by Niwa[9], it is destroyed by heating at 75° C for 0·5 h. The substance adsorbs to paper, to Seitz and candle filters and to some extent to sintered glass filters. Perhaps for this reason yields obtained by curtain electrophoresis were low. Fractionation in diethylaminoethyl cellulose (DEAE) columns, as evident from Niwa's results[9], has resulted in low yields. Niwa's best preparations were obtained by the simple procedure of dialysis and precipitation at a *p*H of 6·2.

It is of interest and possibly significant that in preliminary experiments we have found the mouse protective activity of *B. pertussis* only in the microbial fractions containing histamine sensitizing factor activity. These findings will be reported elsewhere.

PHYSICS

A Time-resolved Spark as a Source for Atomic Absorption Analysis

A HIGH-PRECISION, time-resolved spark which is controlled electronically[1] has been used as a source for the atomic absorption determination of copper, with promising results.

From time-resolved spark investigations the following facts have been ascertained: (*a*) The field strengths and ion concentrations in the spark channel decrease with time. In a spark with a 0·01 farad condenser charged to 20 kV and a discharge duration of about 45 μsec, the ion concentration 10 μsec after initiation of the spark is about 10^{18} ions/cm^3. After approximately 50 μsec the ion concentration has decreased to 10^{17} ions/cm^3. The field strength under those spark conditions changes from about 600 kV/cm to 200 kV/cm (ref. 2) over the same period. (*b*) Pressure broadening appears to be at a maximum during and shortly after the breakdown of the spark gap[3]. (*c*) Self-reversal of resonance lines increases with time. For certain lines, however, the line profiles improve with time[4]. (*d*) For a spark discharge in a point to plane system, with a duration of about 9 μsec, some arc-like and spark lines continue to radiate after the termination of the electrical current[1]. (*e*) An appreciable improvement in line to background intensity ratios of resonance lines may be achieved by increasing the inductance in the spark discharge circuit[5].

The light source used for atomic absorption spectroscopy should give atomic spectral lines with narrow bandwidths[6]. Considering these requirements, it was realized that a spark might be used as a source for atomic absorption analysis if the radiation, after the termination of the electrical current, is used for absorption.

Table 1. EXCITATION CONDITIONS

Type of spark: electronically controlled high-precision spark

Peak voltage	17 kV
Capacitance	6,000 μfarad.
Inductance	residual (5–6μ henry)
Control gap electrodes	tungsten wtih 2 per cent thorium
Control electrode gap	3·6 mm
Analytical electrodes	point to plane top, ¼″ spherical bottom, 2¼″ diameter aluminium disk containing about 0·3 per cent copper
Analytical electrode gap	6·0 mm
Duration of a single discharge	9·3 μsec
Prespark period	10 sec
Exposure period	50 sec
Time-resolved portion	9–11 μsec

If an accurately timed spark with the conditions listed in Table 1 is used, and the radiation restricted to 9–11 μsec after initiation of the spark, the following is further achieved: (1) Doppler-broadening is reduced to a minimum with minimum inductance in the discharge circuit. In this way thermal radiation is restricted. (2) Stark broadening is reduced by at least one order of magnitude accepting the results of Bardócz[2]. (3) Self-reversal of the resonance line is reduced to a low value by using a low copper concentration in an aluminium alloy. (4) Reasonable line to background ratio is obtained[1]. This ratio can be improved by adding inductance for the circuit, but due to the increased thermal excitation, Doppler broadening will increase the line-widths.

To investigate the use of the spark as a source for atomic absorption analysis, the light from the spark was passed through a low-temperature flame into which copper solutions were sprayed. The intensities of the spectral lines were measured with a medium Hilger quartz spectrograph fitted with a direct-reading head[7]. In Table 2 some results of the absorption measurements are given.

Table 2. ATOMIC ABSORPTION RESULTS OBTAINED ON COPPER SOLUTIONS WHEN A SPARK IS USED AS A LIGHT SOURCE

Solution	Line pair $\frac{3247\ \text{Cu I}}{2816\ \text{Al II}}$	$\frac{3247\ \text{Cu I}}{3066\ \text{Al}}$	$\frac{3247\ \text{Cu I}}{\text{background*}}$
Water	0·786, 0·783†	1·29, 1·26	1·61, 1·65
80 p.p.m. Cu	0·758, 0·756	1·26, 1·26	1·59, 1·63
500 p.p.m. Cu	0·663, 0·660	1·10, 1·13	1·40, 1·45

* Background measured in the region of 4000 Å.
† Results for two exposures are given.

As is to be expected, the method is appreciably less sensitive than conventional methods using a hollow cathode lamp as a source, because of the wider spectral lines. However, the results have shown that a spark may be useful as an atomic light source for certain applications. Further research is being conducted to investigate: the possibility of using complex alloys or powders for multi-element analysis; which elements can be determined simultaneously; what spark conditions will give the most satisfactory results; what concentrations of the alloying elements can be used.

Electrical Behaviour of Egg Albumen Solutions at Ultra-High Frequencies

FROM previous work[1,2] it is known that egg albumen, in common with other protein solutions, exhibits dielectric dispersion at megacycle frequencies and microwave frequencies due to the relaxation of the protein and water molecules, respectively. The measurements recorded here, however, indicate that there is another small dispersion region occurring at tens and hundreds of megacycles between the two main regions which is similar to the effect reported by Schwan[3] for the case of hæmoglobin.

An 8 per cent solution of egg albumen was prepared by dissolving crystalline egg albumen in conductivity water, the albumen being supplied by Armour, Ltd., with less than 1 per cent ash and 5 per cent moisture. The pH of the solution was 4·86 and the ionic conductivity 2·43 × 10^{-4} ohm^{-1} cm^{-1} at 1,000 c/s and 25° C.

The real (ε') and imaginary (ε'') parts of the dielectric constants were measured at six different frequencies using previously described apparatus and techniques[4] with recent modifications[5], and the dipolar contribution to ε'' was obtained by subtracting the correction due to ionic conductivity. The dielectric decrement (δ) and the absorption increment ($\Delta\varepsilon''$) were then calculated at each frequency by finding the difference between ε' and ε'' and the corresponding values for pure water, and then dividing these differences by the concentration. All measurements were made at 25° C in order that the results could be compared directly with those of Oncley and Buchanan *et al.*[1] made at lower and higher frequencies, respectively.

The results are shown in Fig. 1, which illustrates significant variations of δ and $\Delta\varepsilon''$ with frequency, despite the large experimental error which arises from taking a small difference between two large quantities. By extrapolating his megacycle measurements to high frequencies Oncley obtained $\delta = 0{\cdot}7$ and, conversely, by extrapolation of microwave measurements to lower frequencies Buchanan obtained $\delta = 0{\cdot}95$. These two results taken in conjunction also indicate subsidiary dispersion, a conclusion consistent with the present work.

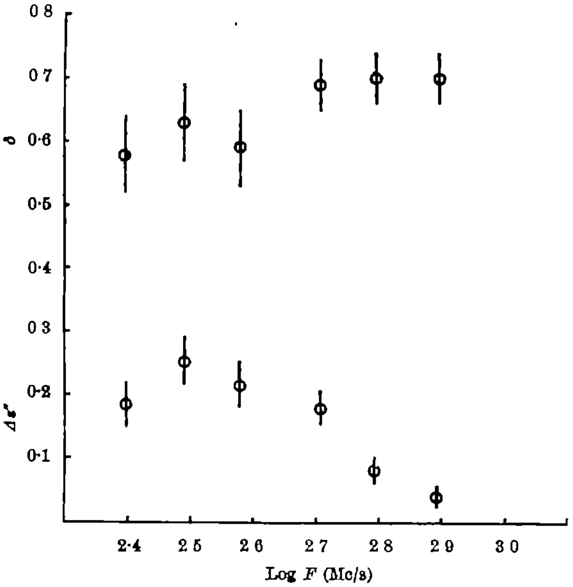

Fig. 1. Variation of dielectric decrement and absorption increment with frequency

In his measurements on hæmoglobin, Schwan[3] noticed similar subsidiary dispersion and suggested that this was consistent with a range of relaxation frequencies extending from 40 Mc/s to 3,000 Mc/s. In the present work, however, it seems unwise to draw detailed conclusions about the characteristics of the dispersion except to point out that there appears to be a suggestion of a maximum in $\Delta\varepsilon''$ at about 300 Mc/s.

It is interesting to consider the significance of this dispersion at a molecular level. In previous measurements[6] which I made on human serum albumen a high value of $\Delta\varepsilon''$ was recorded at one frequency (580 Mc/s) and it was suggested that this could be due to incorrectly assuming that the ionic conductivity was the same at 580 Mc/s as at 1,000 c/s. Such an explanation, however, could not account for the present results since $\Delta\varepsilon''$ is seen to increase with decreasing frequency. Thus it seems likely that a relaxation mechanism is involved and possibilities would include the rotation of individual amino-acid groups within the molecule and rotation of the bound water. It is hoped to investigate these possibilities further by extending the work to cover several proteins over a wide frequency and temperature range.

I thank Mr. J. M. Richards for preparation and measurement of the pH of the egg albumen solutions.

GEOPHYSICS

Selective Volatilization from Tektites

THE possibility of selective volatilization of certain elements from tektites during the fusion process is of importance for the interpretation of their chemical composition. Lovering[1] has pointed out that if tektites were formed by the impact of large meteorites, ultra-high temperatures must have prevailed over large areas of the site, thus permitting appreciable selective volatilization, and, further, that if significant volatilization has occurred, tektites could be derived from certain acid igneous differentiates but not from normal argillaceous sediments.

On the other hand, Cohen[2] has observed a depletion of germanium (a volatile element) in tektites, and states that this must represent an original low germanium content in the parent material, since germanium is not commonly lost from silicate melts in glass tanks. If, however, an ultra-high fusion temperature of tektites cannot be precluded, the glass tank analogy may not be appropriate since the viscosity of the melt decreases approximately exponentially and the diffusion coefficient increases approximately exponentially with temperature[3].

The length of time to which tektites could have been exposed to temperatures greater than 2,000° K is limited to a maximum of a few minutes, as shown by the presence of lechatelierite particles and the alkali elements[4,5]. It may be thought that this evidence precludes an ultra-high fusion temperature for tektites. That this is not the case may be seen from a simple calculation of cooling times.

The approximate equation for the radiative cooling of a spherical black-body can be derived from the Stefan–Boltzmann radiation law as[6]:

$$t = \frac{r\rho c}{9\sigma}\left[T(t)^{-3} - T(0)^{-3}\right]$$

where r is the radius, c the specific heat, σ the Stefan–Boltzmann constant, ρ the density, $T(0)$ the assumed fusion temperature, and $T(t)$ is the temperature of the

Table 1. RATE OF COOLING OF TEKTITES

$T(t^\circ)$ K	Cooling time (sec) from 10,000° K to $T(t^\circ)$ K $r = 1$ cm	 $r = 5$ cm
5,000	0·29	1·43
3,000	1 48	7·40
2,000	5 05	25·2
1,000	40 8	204
500	326·4	1,632

body after t sec. Solving this for the time required for a tektite of 1 cm radius and of 5 cm radius using the values $\rho = 2{\cdot}4$ g/cm and $c = 0{\cdot}21$ cal/g-mol. deg. (value from Grant quoted in ref. 7) gives the results shown in Table 1. Calculations by Prof. J. C. Jaeger (personal communication) show that if the effect of the finite thermal conductivity is taken into account, the figures in Table 1 are not significantly altered. Further, since the molten material is ejected from the impact site at velocities of several kilometres per second, heat shielding would not be expected to affect these figures significantly. The original fusion temperature was arbitrarily taken as 10,000° K for the purposes of calculation, and no implication as to the actual prevailing temperature is intended. In fact, this temperature was chosen because it is probably greater than the vaporization point of tektites. Thus the figures in Table 1 indicate that the rate of cooling from any temperature at which tektites could exist is so rapid that the presence of lechatelierite particles and the alkali elements does not preclude an ultra-high temperature origin for tektites.

It should be noted, however, that even the vaporization temperature of tektites does not necessarily put an upper limit on the temperature of their formation since they could be flash-melted well above this point without actually vaporizing. In the d.c. arc, operating at temperatures of 3,000°–8,000° C, minutes are required, rather than seconds, completely to volatilize milligram quantities of silicates. The data in Table 1 indicate that tektites weighing less than 200 g would have achieved a temperature of 3,000° K in less than 5 sec regardless of the original fusion temperature.

Although the extent of volatilization losses depends on the fusion temperature one assumes, it is not necessary to assume that vaporization temperatures have been achieved. It is well known to spectrographers that significant losses of the alkali elements occur within seconds of striking the d.c. arc at temperatures of 3,000° C[8].

These calculations do not, of course, give any evidence that tektites have in fact been subjected to ultra-high temperatures; but they indicate that such a possibility, with the concomitant implication of significant selective volatilization, must be seriously considered. Evidence that selective volatilization from tektites has occurred will be presented elsewhere.

We thank Prof. J. C. Jaeger for helpful discussions.

CHEMISTRY

Bimolecular Substitution in Octahedral Transition Metal Ions, and the Concept of Amphiphilicity

THE problem of assigning mechanisms to certain octahedral substitution reactions has been complicated by two principal ambiguities. If the reacting complex has acidic protons on the non-participating groups, second-order kinetics resulting from substitution by basic anions may indicate either an S_N2 or an S_N1CB mechanism, and, in general, it is difficult to distinguish the two. With non-basic substituting anions or systems without extractable protons, first-order kinetics may indicate either an S_N1 mechanism or substitution involving preliminary bimolecular solvent intervention. The compound *cis-bis*-pyridino-*bis*-*o*-phenanthroline ruthenium II perchlorate, *cis*-$[\mathrm{Ru\ phen_2\ py_2}](\mathrm{ClO_4})_2$, has no extractable protons, and therefore should give a unique answer to the first ambiguity; and it was hoped that dry solvent acetone would not engage in preliminary bimolecular substitution.

The following reactions were carried out under kinetically controlled conditions in dry acetone: *cis*-$[\mathrm{Ru\ phen_2\ py_2}]^{2+} + X^- \rightarrow$ *cis*-$[\mathrm{Ru\ phen_2\ py}\ X]^+ + \mathrm{py}$, where X = Cl, Br, I, NCS (nitrogen bonding), N_3, and NO_2. Using dry *o*-dichlorobenzene, the same substitutions were carried out, together with those of the extra two anions, OH^- and CN^-, but in less detail than the acetone reactions. In all cases the complex was introduced as the perchlorate and the anions as their tetraphenyl arsonium salts. Although ion-pair formation is likely between the positive and negative species in these solvents, there are good reasons for believing that this phenomenon does not greatly qualify the general conclusions in regard to the mechanisms which will be put forward here.

In acetone the anions Cl^-, Br^-, I^-, and NCS^- reacted by a first-order process; the rate depended only on the concentration of the complex and was independent of the nature and concentration of the anion. Moreover, for these four anions a mass-law retardation and ionic-strength acceleration were observed. The N_3^- and NO_2^- anions substituted at a rate which was dependent on the concentration of the complex and also on the nature and concentration of the anion; the NO_2^- anion substituted considerably faster than the N_3^- anion, the reaction of which in turn was much faster than the first-order reactions. At 100° C, the relative ratios (Cl^-, Br^-, I^-, NCS^-): N_3^- : NO_2^- of the rates was 1 : 4 : 9, and, furthermore, the activation energy of the NO_2^- reaction was 7 kcal less than that of the Cl^-, Br^-, I^-, and NCS^- reactions. A similar pattern was observed in *o*-dichlorobenzene, except that the OH^- anion substituted by a first-order process and at the same rate as the anions Cl^-, Br^-, I^-, and NCS^-, but CN^- substituted fastest of all the anions (including N_3^- and NO_2^-) by a second-order process. If optically active complex was used all the substitutions (independent of order) proceeded with complete retention of configuration.

These results are interpreted as follows: substitution by anions which proceed by a first-order process are unimolecular, and the second-order reactions are bimolecular. The anions therefore divide themselves mechanistically into two categories, and it is notable that only those anions (N_3^-, NO_2^-, and CN^-), which have potentially vacant p-orbitals for π-bonding,

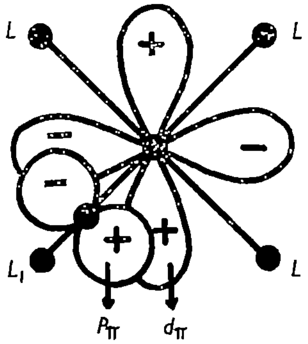

Fig. 1

engage in bimolecular substitution. The anions (Cl^-, Br^-, I^-, NCS^-, and OH^-), having no such orbitals sufficiently low-lying in energy, substitute by a unimolecular process. It seems plausible to conclude that vacated $p\pi$ orbitals of the incoming group are involved in the substitution process, and that the greater stability afforded to the incoming group by π-bonding is necessary to carry the bimolecular reactions through to completion.

A group which engages in a substitution reaction of the foregoing type, because it simultaneously donates and accepts electrons, may be called 'amphiphilic', and a bimolecular amphiphilic substitution reaction may be symbolized as $S_A{}^2$. The nature of these bimolecular substitution reactions may be envisaged as follows. The incoming group attacks an octahedral edge and donates its lone pair of electrons to the highly positive ruthenium atom; at the same time a vacated $p\pi$ orbital on the donor atom of the incoming group accepts electrons from the filled $d\varepsilon$ subshell of the ruthenium. A plausible mode of donor π-orbital overlap is that illustrated in the diagram, in which the four ligands (L) are at the corners of the square, and two others (not shown) are above and below the plane.

The incoming ligand is situated at an octahedral edge and the $p\pi$ orbital overlaps laterally with the $d\varepsilon$ orbital the longitudinal projection of which is towards the outgoing ligand L_1.

In the system, *cis*-[Ru phen$_2$ py$_2$]$^{2+}$, it is likely that the pyridino groups are stabilized, to some extent, by $d\pi$—$p\pi$— double bonds. Experiment shows that simple σ-donors are ineffective as bimolecular substituting agents, but that groups which are both σ-donors and π-acceptors are effective. This seems to imply that, in the foregoing system, both ρ- and π-bonding is required to release the π-bonded pyridino groups from the complex by a bimolecular mechanism. In the bimolecular transition state of the foregoing reactions, the incoming and outgoing groups must share a $d\pi$ orbital, and thus, relative to the ground-state, the incoming group will be stabilized and the outgoing group be destabilized by the partial transference of the $d\pi$ bond to the incoming group. Therefore π-bonding in the transition state promotes both the bond making and the bond breaking components of this bimolecular mechanism.

In analysing the amphiphilic order of a series of reagents several electronic factors must be discussed, relating to the metal and ligand orbitals available. Probably the best single experimental criterion which embraces, to some extent, all these factors is the *trans*-effect in platinum II complexes. It is proposed that for a given charge series the amphiphilicity will follow the *trans*-effect in platinum II complexes. Amphiphiles with the strongest *trans*-effect will have the highest amphiphilic power. Arsines, phosphines and sulphides might be considered potentially amphiphilic reagents using empty $d\pi$ orbitals in the transition (and final) states. There are clearly others; but it is notable that the reagents used here do, in fact, follow the *trans*-effect series, that is, $CN^- > NO_2^- > N_3^- > NCS^-$, I^-, Br^-, Cl^-, OH^-.

I thank Prof. D. P. Craig, Sir Christopher Ingold and (the late) Prof. F. P. Dwyer for helpful discussion.

Absorption Correction in the Viscometry of Dilute Solutions of High Polymers

In a private communication, Drs. S. Gundiah and S. L. Kapur (of the National Chemical Laboratories, Poona, India) have pointed out to us that the derivation of the principal equation in our earlier communication[1] is in error, and that there is, because of this, a term missing from the equation. We acknowledge the error and are grateful to them for detecting it; but we wish to make it clear that the missing term should be negligible not only for the system we used as an example, but also for all systems of the type we specified, namely, "dilute solutions of high polymers". In this communication, then, we provide (*a*) a correction for the record and (*b*) additional evidence that the method we proposed is both sound and useful, and applicable to a wide variety of systems.

(*a*) The third paragraph of the earlier communication should be replaced by the following:

From this it follows that, in sufficiently dilute solutions:

$$\frac{t_{sp}}{c} = \left(1 + \frac{4a}{R}\right)[\eta] + k'\left(1 + \frac{4a}{R}\right)[\eta]^2 c + \frac{4a}{R} \cdot \frac{1}{c} \qquad (2)$$

and

$$\frac{\ln t_r}{c} = [\eta] - (\tfrac{1}{2} - k')\,[\eta]^2 c + \frac{4a}{R} \cdot \frac{1}{c} \qquad (3)$$

for in such solutions:

$$\frac{\ln t_r}{c} = \frac{\ln\,(1 + t_{sp})}{c} = \frac{t_{sp}}{c} - \frac{\tfrac{1}{2}\,(t_{sp})^2}{c} + \ldots$$

Subtracting (3) from (2), we obtain:

$$\frac{t_{sp}}{c} - \frac{\ln t_r}{c} = \frac{4a}{R}\,[\eta] + \left(\frac{1}{2} + k' \cdot \frac{4a}{R}\right)[\eta]^2 c \qquad (4)$$

In this equation, the term $4a/R\ .\ 1/c$ (the most significant of the absorption terms in equations (2) and (3)) does not appear. Moreover, the term $k'\ .\ 4a/R$ is, for high polymer systems, small compared with $\tfrac{1}{2}$. Equation (4) thus reduces to the simple equation:

$$\frac{t_{sp}}{c} - \frac{\ln t_r}{c} = \frac{4a}{R} \cdot [\eta] + \frac{1}{2}\,[\eta]^2 c \qquad (5)$$

and hence a value of $[\eta]$ that is unaffected by 'absorption' can be evaluated from the slope of the plot of:

$$\frac{t_{sp}}{c} - \frac{\ln t_r}{c} \text{ vs. } c$$

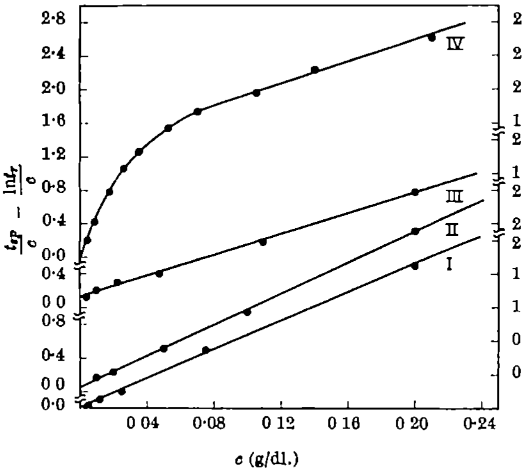

Fig. 1 Plot of $\frac{t_{sp}}{c} - \frac{\ln t_r}{c}$ versus c for data from refs. 6, 7, 8 and 9

Scale for I ordinate × 10^{-1}, abscissa × 10
II ,, × 10 , ,, × 10
III ,, × 10 , ,, × 1 in volume per cent

(*b*) The method we proposed for detecting absorption or wall effects and eliminating their influence on the intrinsic viscosity is based on equation (5) of the corrected paragraph in (*a*) above. Its soundness depends, therefore, on the validity of the assumption that the term $k' . 4a/R$ in equation (4) may be neglected. Some typical examples illustrate that this term is indeed negligible. For polymers (excluding polyelectrolytes) k' falls in the range 0·25–0·6, and a, the thickness of the absorbed layer, will be in the range of a typical particle diameter, 1000–6000 Å. In viscometers the smallest practicable capillary radius, R, is about 0·025 cm. With the typical values $k' = 0{\cdot}3$, $a = 1250$ Å, and $R = 0{\cdot}025$ cm, $k' . 4a/R$ equals $0{\cdot}6 \times 10^{-3}$. This term is therefore very small in comparison with $\frac{1}{3}$; its neglect introduces an error of only 0·1 per cent. Even with extreme values ($k' = 0{\cdot}6$, $a = 6000$ Å) the error would be only 1 per cent, and the error in the determination of $[\eta]$ using equation (5) would be well within the usual experimental error of determining $[\eta]$. Use of the more complete equation (4) would be necessary only if k' or a (or both) were exceptionally large; we have been unable to find data for such systems among polymer-solvent systems in the literature. (With polyelectrolytes in solvents of low ionic strength, however, the magnitude of k' and hence of $k'.4a/R$ may be such as to preclude the use of our method. Such cases will be considered elsewhere.)

It should be emphasized that use of equation (5) makes it possible to determine whether measured viscosities (or related functions) are affected by absorption or wall effects. Upward curvature, as c decreases, in a plot of t_{sp}/c vs. c has been attributed to absorption[2], to a wall effect[3], to expansion of the polymer coil[4], to electroviscous effects (with polyelectrolytes)[5], etc. If in the region where a plot of t_{sp}/c vs. c is curved, a plot of $(t_{sp}/c - \ln t_r/c)$ vs. c is a straight line passing almost through the origin, one may conclude that absorption and/or wall effects are significant and responsible for the curvature. If, on the other hand, the $(t_{sp}/c - \ln t_r/c)$ vs. c plot also is curved, some other explanation must be sought.

To illustrate the validity and value of these procedures we have applied them to four different systems for which data are available in the literature. (For each of these systems, plots of η_{sp}/c vs. c have been published displaying marked upward curvature that might be ascribed to absorption.)

For the systems polyvinyl acetate in butanone[6] and polyisobutylene in decalin[7], data plotted as $(t_{sp}/c - \ln t_r/c)$ vs. c yield the lines I and II of Fig. 1. Each of these is a straight line—a result consistent with the explanation that absorption effects are responsible for the upward curvature in the η_{sp}/c vs. c plots. Moreover, with each system the intrinsic viscosity calculated from the slope of the straight line (using equation (5)) is in good agreement with the value obtained by extrapolation using η_{sp}/c values obtained at higher concentrations.

With silver iodide sols (ref. 8, 'solutions' *IB*), and with aqueous solution of sodium pectinates[9], the data yield lines III and IV of Fig. 1. For the silver iodide sols a straight line is obtained. This provides support for the suggestion made[8] that the upcurve may be due to an absorption effect—a "slight flocculation on the wall of the capillary". (Again, the intrinsic viscosity calculated from the slope is in good agreement with the intrinsic viscosity obtained, with higher concentration data, in the usual way.) On the other hand, the sodium pectinate data do not yield a straight line, but a line with the downward curvature that would be expected with a polyelectrolyte effect.

Gas Chromatographic Analysis of C_1–C_4 Hydrocarbons with open Tubular Columns

SINCE their invention by Golay[1], the use of open tubular columns with liquid phase coating on the inside wall became one of the most important techniques of gas chromatography. The use of open tubular columns permits the analysis of complex mixtures with high efficiency. It was, however, felt that the use of such columns for low-boiling hydrocarbons (below C_4) is possible only at 'very low' temperatures[2]. According to our best knowledge, the separation of methane, ethane and ethylene with open tubular columns was not yet reported.

During a recent work, we checked the gas hold-up (the 'retention time of the air peak') of some open tubular columns coated with silicone oils and greases which were used in connexion with a flame ionization detector, by using methane or more correctly mixtures of C_1–C_3 hydrocarbons. The use of methane for such measurement is generally accepted since the flame ionization detector has no response for air. To our surprise, we did find some separation for these components.

Using a 300-ft. long column with 0·010 in. inside diameter and coated on the inside wall with '*DC*–550' phenyl silicone oil, we found that when operating it at

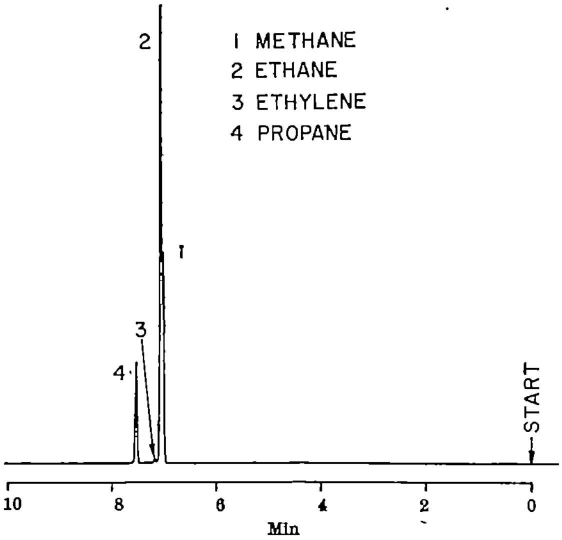

Fig. 1. 300-ft., 0·010-in. internal diameter open tubular column with '*DC-550*' phenyl silicone oil as liquid phase. Column temperature, 22° C. Sample volume, 1 ml. gas mixture, approx. 1/100 split. Carrier gas (helium) inlet pressure: 30 lb./sq. in.

room temperature, a partial separation between methane and ethane and a complete separation from ethylene and propane could be observed (Fig. 1). For this chromatogram, a chart speed of 1 in./min and a potentiometer recorder with 1 sec full-scale pen speed (Leeds and Northrup 'Speedomax *G*', 5-mV recorder) was used. We are quite sure that with faster pen and chart paper, the separation between the first two peaks would be even better.

By cooling the column, the separation could be improved. However, 'very low' column temperatures are not needed. The chromatogram on Fig. 2, for example, was made keeping the column at 5° C.

Another very interesting result was obtained when a second gas mixture was injected into a 150-ft.-long open tubular column with 0·010-in. internal diameter, prepared by using Dow Corning silicone high-vacuum grease as liquid phase. As shown in Fig. 3, excellent separation between methane and ethane could be obtained at room temperature.

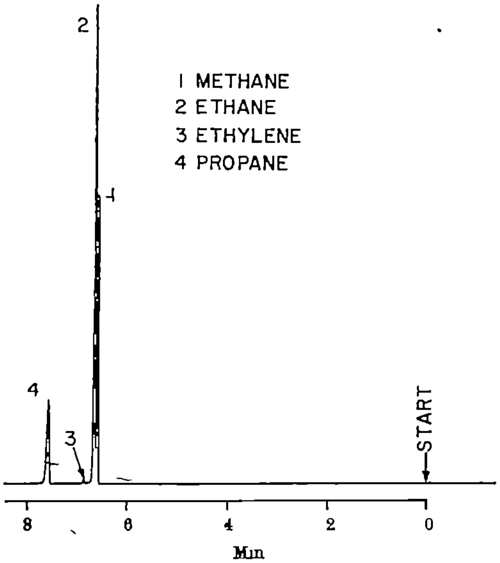

Fig. 2. Column and sample volume as on Fig. 1. Column temperature, 5° C. Carrier gas (helium) inlet pressure: 35 lb./sq in.

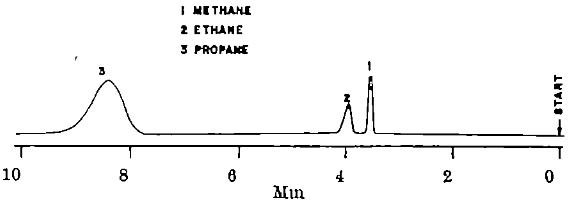

Fig. 3. 150-ft., 0·010-in. internal diameter open tubular column with Dow Corning silicone high vacuum grease as liquid phase. Column temperature, 22° C. Sample volume, 1 ml. gas mixture, about 1/100 split. Carrier gas (helium) inlet pressure. 20 lb./sq. in.

It should be mentioned that the silicone high-vacuum grease used for the preparation of this column also contains some colloidal silica. Thus, in our opinion, the chromatogram on Fig. 3 can actually be attributed partly to gas adsorption chromatography rather than to gas-liquid partition chromatography alone. However, adsorption columns in which the active adsorbent is distributed in a liquid phase coated on the inside wall of a capillary tube were not yet reported.

Naturally, such columns were used many times by different authors at higher temperatures. In such circumstances, however, the liquid phase—and not the adsorbent—is the active components.

We thank Dr. P. F. Varadi, of Machlett Laboratories, Springdale, Conn., for directing our attention to this problem.

Quantitative Determination of Griseofulvin

For the determination of griseofulvin or 7-chloro-4,6-dimethoxy cumaran-3-one-2-spiro-1′-(2′-methoxy-6′-methyl*cyclo*hex-2′-ene-4′-one)[1], spectrophotometric[2–4], and spectrophotofluorometric[5] methods have been described. Colour reactions[6] are known which have been used for the identification of this antibiotic.

A method based on a colour reaction has been evolved in this laboratory for the quantitative determination of griseofulvin. In the course of experiments the feasibility of coupling an azo-component to the unsubstituted C_5-atom of the aromatic ring of the molecule was investigated.

Theoretical considerations and experimental evidence have shown that this coupling cannot be carried out on the intact molecule because the carbon atom in question does not possess the electron density necessary for an electrophilic substitution reaction.

A product amenable to coupling with a diazo-component is obtained through hydrolysis when griseofulvin is subjected to the action of a strong acid, or of a strong base, in suitable circumstances. The concentration of griseofulvin is indicated by the intensity of the colour of the azo-derivative of this hydrolysis product.

The optimum conditions for hydrolysis in solutions of hydrochloric acid or potassium hydroxide of different concentrations, and as functions of time, have been determined experimentally. The method consists of mixing 4 ml. of a solution of griseo-

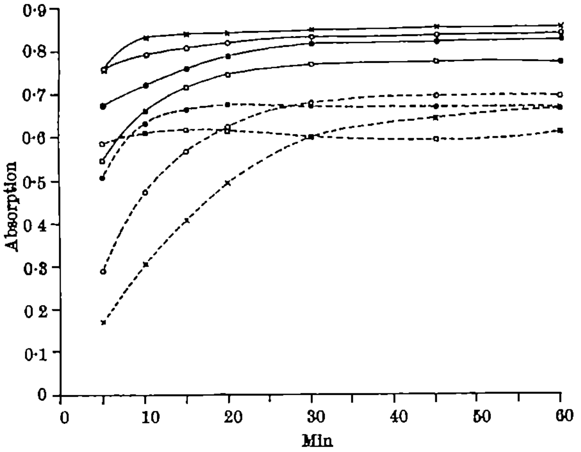

Fig. 1. Colour intensity of the azo-dye as a function of the circumstances of hydrolysis of griseofulvin. Hydrolysing agent, N HCl (— — × — —); 2 N HCl (— — ○ — —); 4 N HCl (— — ● — —); 8 N HCl (— — □ — —); N KOH (——×——); 2 N KOH (——○——); 4 N KOH (——●——); 8 N KOH (——□——)

fulvin (25 μg/ml. in 85 per cent v/v ethanol) with 2 ml. of hydrochloric acid or potassium hydroxide solutions of varied concentrations and keeping this mixture in a thermostat at 80° C for various times. After this, neutralization, respectively with a solution of pyridine or acetic acid, follows. Then 2 ml. of a 0·5 per cent aqueous solution of the stabilized diazonium salt of 4′-amino-2′,5′-dimethoxybenzanilide ('Echtblau *RR*') is added, and this mixture (final volume 10 ml.) is placed in a thermostat at 80° C for 8 min to achieve full development of colour. After cooling to room temperature, extinction is measured at $\lambda = 495$ mμ against a blank solution. The results are shown in Fig. 1.

It can be seen that for hydrolysis treatment with potassium hydroxide is more effective than treatment with hydrochloric acid. The optimum stage is reached with N potassium hydroxide after treatment for 30 min. Using other diazo-components for coupling, products with other colours are obtainable; Fig. 2 shows the adsorption curves of some of these.

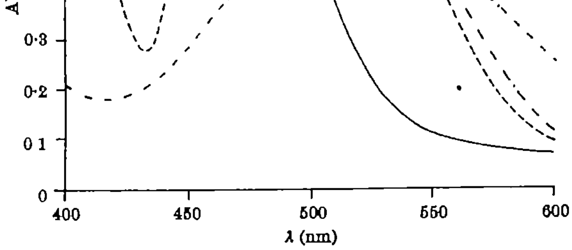

Fig. 2. Absorption spectra of different azo-dyes formed with different azo-compounds. Bases corresponding to the diazo-components: *o*-dianisidine (————); 4′-amino-2′,5′-dimethoxybenzanilide (— — —); *N*-phenyl-*p*-phenylenediamine (—·—·—); 2,6-dichloro-2′,5′-dimethoxy-4-nitro-4′-aminoazobenzene (—··—)

When hydrolysis is carried out with an N potassium hydroxide solution for 30 min., there is a linear relationship between the extinction values measured at maximum absorption, and the concentrations of griseofulvin in the coloured solutions prepared with the different diazo-compounds. The calibration chart shows a straight line meeting the origin of the co-ordinates. Average deviation from the straight line within the concentration limits of 5 μg/ml. and 50 μg/ml. is ± 0·5 per cent. The colour of the solutions to be measured remains stable for two hours.

Measurements of absorption were carried out on a Unicam *SP* 500 spectrophotometer, using a 10-mm cell.

Crystalline griseofulvin was used. Based on this colour reaction, experiments are being carried out to establish a method for the determination of griseofulvin in various preparations, and fermentation broths. It is to be hoped that disturbing effects of impurities can be eliminated to allow adequate spectrophotometric determinations to be carried out.

A Comparison of Polysaccharides of *Hypnea musciformis* and *Chondrus crispus*

A REVIEW of the literature gives some evidence which indicates that the polysaccharides of *Hypnea* species and *Chondrus crispus* (carrageenin) are identical. Clingman's study of *H. specifera*[1] showed these polysaccharides to contain D-galactose and 3,6-anhydro-D-galactose, the same basic components found on analysis of *Chondrus* extracts[2]. *Hypnea* extractives have a potassium-sensitive fraction (termed the κ-fraction[3]), as does *Chondrus*[3], which are degraded by a cell-free bacterial preparation from *Pseudomonas carrageenovora*. This preparation is reported to be specific not just for carrageenin but for its κ-fraction[4].

Evidence suggesting that polysaccharides from the algae are not identical may also be found in recent literature. Pronounced differences in gel strength between extractives of *H. musciformis* and *C. crispus* have been reported[5]. Furthermore, the cell-free bacterial preparation described by Yaphe[4] has been found to degrade another polysaccharide, fucoidin[6].

It was felt that an examination of the oligosaccharides produced by mild hydrolysis of the algal extracts would show any differences in arrangement of the D-galactose and 3,6-anhydro-D-galactose units, thus helping to explain the dissimilarities which have been noted.

Samples of *H. musciformis* and *C. crispus*, picked clean by hand, were washed well with sea-water, rinsed with a minimum of distilled water and lyophilized. The algae were ground in a Wiley mill to pass an 80-mesh screen. Weighed amounts were suspended in borate buffer (*p*H 9·0, i.e. 0·05) and disrupted in a Lourdes mixer for 20 min at 15,000 r.p.m. with cooling. The samples were then made to 1·0 per cent (w/v) in the buffer and stirred at 80° C for

1 h. The resultant mixture was clarified by centrifugation at 2,000*g* and the cell debris discarded. The supernatant was exhaustively dialysed first against the buffer and then against water adjusted to *p*H 9·0 with sodium hydroxide. A portion of each algal extract was treated with three volumes of 95 per cent ethanol and the precipitate collected and dried to constant weight *in vacuo* at 35° C over sodium hydroxide. The remainder of the extracts were fractionated by the method of Smith[3]. A portion of each of the fractions thus isolated was subjected to mild hydrolysis using the procedure of Painter[7], with one modification, that is, a small amount of 'Dowex 50' (H+ form) was mixed with the samples in the dialysis bag in an effort to force the hydrolysis to completion. The dialysates so obtained were passed through a cation exchange column ('Amberlite 200', H+ form, 16–20 mesh) to convert the barium salts of the sulphated sugars to their free acids and to remove the excess barium remaining in solution. The effluents were concentrated by evaporation under reduced pressure at 60°–80° C.

The original, untreated fractions as well as the dialysates and dialysants of the treated fractions were compared chromatographically using the following solvents and papers: (*a*) 1-butanol/acetic acid/water (50 : 12 : 25), Whatman No. 3*MM*, descending; (*b*) 1-butanol/ethanol/water (3 : 1 : 1) made to 3 per cent with cetylpyridinium chloride ascending: (*c*) water saturated methyl ethyl ketone made to 3 per cent with cetylpyridinium chloride, Whatman No. 54 and No. 3*MM*, ascending, both after Rees[8]. Electrophoretic separation was carried out on a horizontal cell in borate buffer (*p*H 8·3, i.c. 0·05) using Whatman papers No. 54, No. 4, No. 3*MM* and *S* and *S* 507 and cellulose acetate strips (Gerlman Instrument Co., 'Microphore').

By all chromatographic methods, a total of five distinct spots could be easily observed in the dialysates of the whole, previously unfractionated *C. crispus* and *H. musciformis* polysaccharides. In all methods the R_F and R_{gal} of the spots from the two polysaccharides appeared identical. The electrophoretic evidence supported this conclusion. The precipitates prepared by potassium chloride fractionation of the above polysaccharides, termed the ϰ-fraction by Smith[3], showed the same five components after hydrolysis. The hydrolysates of the λ-fractions of the two polysaccharides, which do not precipitate on treatment with potassium chloride, again appeared identical to each other. They only showed, however, two components in solvent system (*a*) (8-h and 24-h irrigations) and four in systems (*b*) and (*c*). Chromatography of unhydrolysed and unfractionated polysaccharides, as well as their unhydrolysed ϰ- and λ-fractions, yielded only one spot, at the origin. Similar results were obtained with the dialysants, making it apparent that the hydrolysis had not gone to completion, even with the addition of extra resin.

From the results presented, together with that of others[1,3,4], we consider it reasonable to assume that both the basic structural units and the mode of their linkage in the polysaccharides derived from *C. crispus* and *H. musciformis* are identical. Observed differences between the two may, therefore, be due to such other factors as cation concentration, degrees of hydrogen bonding, or polysaccharide concentration (particularly in commercial preparations). More specifically the concentration of the ϰ-fraction, which possesses great gel strength, may vary seasonally[6] and is present normally in greater proportion in *H. musciformis* than in *C. crispus*.

BIOPHYSICS

Concentration Dependence of Sedimentation Coefficient of Deoxyribonucleic Acid with added Sodium Chloride

The addition of sodium chloride has a marked effect in reducing the electrostatic interaction between deoxyribonucleic acid (DNA) molecules in solution, as is shown by the decrease in the slope of the concentration dependence of reduced viscosity ($\eta_{sp}/c.$) with the increase of added salt[1,2]. This work shows that the same information can also be obtained from the variation of the concentration dependence of sedimentation coefficient of DNA with the addition of sodium chloride. Fig. 1 is a plot of the reciprocal of the sedimentation coefficient, $1/S_{20,w}$ versus DNA concentration, at sodium chloride concentrations of 0·001 M, 0·01 M, 0·1 M, 0·15 M and 0·2 M. Changes in the slope of the curves as well as a constant extrapolated value of sedimentation coefficient at zero concentration, $S^0_{20,w} = 22{\cdot}7 \times 10^{-13}$ sec, at different concentrations of salt, reveal a close similarity between the concentration dependence of reduced viscosity and that of the reciprocal of sedimentation coefficient, in the case of DNA in solution.

It is also evident from Fig. 1 that with increase of concentration of sodium chloride, the sedimentation-rate increases and the region of rapid variation of sedimentation coefficient is shifted to higher concentrations of DNA. The charge on the DNA macro-ion increases with the addition of sodium chloride to DNA solution along with a shift of the region of rapid variation of the charge to higher concentrations of DNA[3].

This shows a close resemblance between the variations of the charge and the sedimentation-rate with concentration of DNA. Thus the two explanations of hypersharp boundary observed at high concentrations of DNA (one, on the basis of rapid variation of sedimentation with concentration[4], and the other, on the rapid variation of charge[3]), perhaps, do not contradict each other.

In this investigation, it has also been observed that the sedimentation boundary of calf thymus DNA remains more hypersharp in 0·001 M sodium chloride up to 0·0045 per cent compared with about 0·009 per cent in higher concentrations of sodium chloride. The schlieren refractive boundary, recorded with the help of a Spinco *E* ultracentrifuge using standard 12-mm aluminium centre-piece cell, is shown in Fig. 2.

In view of the close qualitative similarity between the modes of variation of charge, reduced viscosity and sedimentation with DNA concentration as the

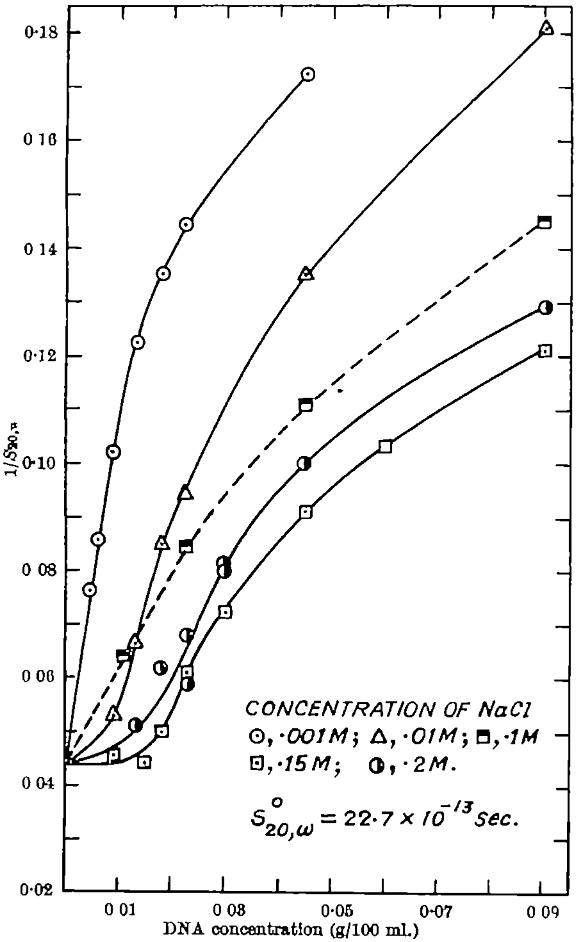

Fig. 1. Variation of the reciprocal of the sedimentation coefficient ($1/S_{20,w}$) with concentration of calf thymus DNA in sodium chloride solvents 0·001, 0·01, 0·1, 0·15 and 0·2 M

result of addition of sodium chloride, a quantitative correlation might provide more information about the DNA molecules in solution.

It is well known that physico-chemical measurements are affected by the quality of DNA preparation and the method of handling the DNA solutions. The sample of calf thymus DNA used in this work (Lot No. 3354, Mann Research Laboratory, New York; phosphorus 8·82 per cent and nitrogen 16·4 per cent) showed the following characteristics. The ultra-violet spectra measured in a *PMQ* II spectrophotometer (Carl Zeiss) showed $E_{259}/E_{231} = 2·5$, $E_{259}/E_{280} = 1·85$, and maximal rise in extinction at 260 mμ 49·3 per cent and $E_{259}/E_{280} = 1·42$ at *p*H 3 (ref. 5).

Fig. 2. Hypersharp schlieren boundary of calf thymus DNA in 0·001 M sodium chloride sedimenting from right to left at 8, 16 and 24 min from the time of reaching 2/3 of the 39,460 rev./min. Bar angles are 18·5°, 18° and 17·5°, respectively. DNA concentration 0·0045 per cent (O.D.$_{259 m\mu}$ = 0·865)

The critical salt concentration for denaturation was between 10^{-3} and 10^{-4} M sodium chloride and the extinction was practically constant between 10^{-3} and 1 M sodium chloride[6]. $E^{1\%}_{1\text{cm}} = 193$ at 0·15 M sodium chloride. DNA solution was prepared according to a recent method[1]. 100 mg of fibre was initially dispersed in 10^{-3} M sodium chloride for 75 h in cold without agitation (0·2 per cent DNA), and 0·09 per cent concentration of DNA solutions in 0·001, 0·01, 0·1, 0·15, 0·2 M sodium chloride were prepared. These were spun after 45 h in a Servall rotor in the cold for 1 h, which resulted in no gel or precipitate. Freshly prepared de-ionized double-distilled water was used and the filling of the ultracentrifuge cell was done with the help of a No. 22 needle. The rotor speed selected was 39,460 rev./min.

Apart from the general conclusions made here from Fig. 1, there are other aspects of the mode of concentration dependence of sedimentation-rate. The inflexion in the curves in 0·01, 0·15 and 0·2 M sodium chloride near 0·01 per cent concentration of DNA is the result of presence of undispersed aggregates, which seems to be the consequence of the mode of dilution[7], namely, each dilution was made from the highest concentration of the stock solution (0·09 per cent). This is also evident from the fact that in the 0·1 M sodium chloride series (stock solution was stored for 4½ months), where dilution was made successively from the next higher concentration, the shape of the curve is different. The former method of dilution did not affect the 0·001 M sodium chloride series, where evidently dispersion of DNA in solution was rapid. In all the cases the minimum time allowed for dispersion in cold was 16 h without agitation.

It is evident that the method of handling the solution of DNA affects the mode of concentration dependence in the region of rapid variation of sedimentation with concentration. But this did not affect the extrapolated value of $S^{0}_{20,w} = 22·7 \times 10^{-13}$ sec. The solution stored for 4½ months in 0·1 M sodium chloride was also not degraded.

It is also observed that the sedimentation-rate is more sensitive to small variation of electrolyte in the lower ionic strength. Hence, any previous salt concentration in the DNA sample will affect the shape of the curve at lower ionic strength. The sedimentation is, however, less sensitive to change of moderately high concentration of salt. As seen in Fig. 1, at extremely low concentration region below 0·01 per cent, under identical methods of handling, the sedimentation-rates may be practically independent of moderately high salt concentrations. But at higher concentrations of DNA the constancy of sedimentation-rate at salt concentrations > 0·1 M sodium chloride, as reported by others[8], has not been found in this work.

The values of $S_{20,w}$ in 0·2 M sodium chloride agree with the recent values of others[3] in the concentration range 0·04–0·09 per cent. The values in 0·15 M sodium chloride series are consistently higher than those in 0·2 M sodium chloride series. The interpretation of this result may be tentatively made as follows. If the rod-like shape for DNA is assumed, the sedimentation-rate will measure the *M*/*L* (mass/length)[4]. Then higher $S_{20,w}$ value at 0·15 M sodium chloride will mean greater *M*/*L*. Similar results on the basis of light scattering measurement showing greater *M*/*L* at 0·15 M sodium chloride compared with that at 0·2 M sodium chloride can be seen in the work of others[2].

One of us (P. K. G.) thanks the Council of Scientific and Industrial Research, India, for a senior research fellowship, and the other (A. L. B.) thanks the Ministry of Scientific Research and Cultural Affairs for a research training scholarship. We both thank Prof. N. N. Das Gupta for advice.

Coefficient of Thermal Conduction: Homogenized Tissues: Thermal Conduction and the Rate of Blood Flow

THE coefficient of thermal conductivity has already been measured for slices of various dog tissues[1], and found to vary from 0·6 × 10^{-3} for fresh lung to 5·5 × 10^{-3} for fresh muscle. The same apparatus can be used for measuring K for homogenized tissues; in general, these have values of K which vary less from each other than do those for tissue slices.

The technique used is the same as that already described, except that chamber II of the apparatus is filled with homogenized tissue instead of fresh tissue slices. The homogenization is carried out for 5 min in a Waring blender; the homogenized tissues are then transferred to plastic centrifuge tubes and spun for 15 min at 10^3g to free them from air. The measurement of K is made after three relaxation times for the tissue have elapsed; chamber I is kept at 28° C, the temperature in chamber II is initially 20° C, and the quantity of heat passing through it to chamber III (initially at about 6° C) during the fourth and fifth relaxation times is found. The steady-state equations are applied to this to find K.

The average values of $K \times 10^3$ (6 determinations for each tissue) for the homogenates are: muscle 3·6, liver 2·5, brain 1·6, and lung 2·0. These can be compared with the values of $K \times 10^3$ for tissue slices: muscle 5·5, liver 3·3, brain 1·7, and lung 0·6. Homogenization thus reduces the value of K for muscle and liver to about 70 per cent, affects the value of K for brain only a little, and raises the value of K for lung by about three-fold. The value of K for water is 1·5 × 10^{-3}, which agrees well with the accepted value. In all cases the variation from the average is not more than ± 10 per cent; this applies to both tissue slices and tissue homogenates.

The conclusion is that the thermal conduction in tissues such as muscle and liver is reduced by homogenization, heat being able to move better in the presence of structural pathways than in their absence; in the case of brain, homogenization makes little difference, and the effect of homogenization in the case of lung is clearly due to the removal of air.

With reference to the hypothermic state in which blood at low temperatures is pumped into the circulation, it is known that all parts of the body are not cooled equally. This may be the result of the flow in some regions or organs being greater than that in others, the result of some tissues conducting heat to a greater extent than do others, or the result of both factors. Suppose that the rate of cooling of an organ, $\Delta\theta/\Delta t$, is entirely dependent on the extent to which it is a thermal conductor. If it is supplied with a constant flow of cold blood, $\Delta\theta/\Delta t$ should be highly and positively correlated with the coefficient of thermal conductivity K; if the correlation is small, $\Delta\theta/\Delta t$ cannot be largely dependent on K, and the conclusion must be that the flow of the blood through different organs varies.

The rate of cooling of a tissue is measured by perfusing cold blood into the femoral artery of the dog and collecting the venous return from the superior jugular and femoral veins. This return is measured in ml./min, and passes to a disk oxygenator, then through a DeBakey rotary pump, then to a Brown–Harrison heat exchanger, and then back to the animal. Calibrated needle thermistors are placed in the tissues in which the rate of cooling is to be measured; these are usually the brain, lung, liver, muscle, and kidney, and thermistors are also placed in the arterial and venous streams. The flow of blood is 10–50 ml./min/kg of the animal's body-weight, and is constant for the time Δt, which is usually an interval of 10–20 min from the beginning of the perfusion of cold blood. The temperature of the tissues falls during this interval and tends to approach that of the arterial blood, the form of the falling temperature curve being that of Newton's law of cooling, that is, log θ being linear with time.

The coefficient of thermal conductivity K is measured for each tissue as already described[1]; $\Delta\theta/\Delta t$ is then correlated with K. The coefficient of correlation r is 0·364 ± 0·181, that is, it is scarcely significant, and so the conclusion is that the rate of cooling of the tissues is determined by the different rates of flow of cold blood through them, and not to a significant extent by their thermal conductivity, variable though this is (a ten-fold variation).

BIOCHEMISTRY

Physical Significance of Michaelis Constants

Briggs and Haldane[1] showed that for the reaction sequence $E + S \rightleftharpoons ES \rightarrow E + P$, the same form of initial rate equation is obtained by the steady-state assumption as by the more restrictive equilibrium assumption of Michaelis and Menten[2]. It was evident, therefore, that the Michaelis constant, K_m, defined[3] as the substrate concentration with which half the maximum rate is attained, is not necessarily equal to the substrate constant, K_s, the dissociation constant of the enzyme–substrate complex. Nevertheless, it is still sometimes assumed[4,5] that the Michaelis constant is a measure of the affinity of the substrate for the enzyme. In a recent text-book[6], it is stated that the Michaelis constant must be either equal to or greater than the substrate constant. It seems worth while to point out that this is not so, and to indicate relationships between K_m and K_s values derived from reaction schemes for reversible reactions involving one and two substrates.

Single Substrate Reactions. For the simple reaction sequence postulated by Michaelis and Menten[1]:

$$E + S \underset{k_{-1}}{\overset{k_{+1}}{\rightleftharpoons}} ES \xrightarrow{k_{+2}} E + P$$

steady-state treatment[2] gives $e/v_0 = 1/V + K_m/V[S]$. where $K_m = (k_{-1} + k_{+2})/k_{+1}$. The necessary and sufficient condition for $K_m = k_{-1}/k_{+1} = K_s$ is that $k_{+2} \ll k_{-1}$, whereby the breakdown of ES to give product is too slow to disturb the equilibrium with enzyme and substrate. (The conclusion[7,8] that this requires $k_{+2} \ll k_{+1}$, deduced from $K_m = K_s + k_{+2}/k_{+1}$, is incorrect, since K_s may also be much less than unity.)

Obviously K_m cannot be smaller than K_s if this simple postulate is valid. The situation is otherwise if two or more enzyme complexes are present in comparable concentrations in the steady state:

$$E + S \underset{k_{-1}}{\overset{k_{+1}}{\rightleftharpoons}} ES \underset{k_{-2}}{\overset{k_{+2}}{\rightleftharpoons}} EP \underset{k_{-3}}{\overset{k_{+3}}{\rightleftharpoons}} E + P$$

Steady-state treatment gives the same form of initial rate equation as before, but the Michaelis constant for S is a complex function of rate constants[9] which may be written:

$$K_m = K_s\left[\frac{k_{-2} + k_{+3} + k_{+2}\,(k_{+3}/k_{-1})}{k_{-2} + k_{+3} + k_{+2}}\right]$$

If $k_{+3} \gg k_{+2} + k_{-2}$, then $K_m = (k_{+2} + k_{-1})/k_{+1}$, as before; the restrictions merely ensure that $[EP]$ is negligible. In general, however, K_m may be greater or smaller than, or equal to, K_s, according to the relative values of k_{+3} and k_{-1}. These are the specific rates of the last steps of the forward and reverse reactions respectively. Therefore, by symmetry, for a reversible reaction, either $K_m = K_s$ in both directions, or if $K_m > K_s$ in one direction, the reverse must be true in the opposite direction.

If three intermediate complexes are postulated, the relations are more complicated[9], but it is still true that if the specific rate of the last dissociation step, which gives the product, is less than the specific rate of dissociation of the ES complex, the dissociation constant for the latter, K_s, will be greater than the Michaelis constant for the substrate.

Two-Substrate Reactions. The Michaelis constant for each substrate in a two-substrate (or coenzyme-substrate) reaction varies in general with the concentration of the other[10]. It seems best[11] to adopt the convention of infinitely large concentration for the other substrate, and to define K_m for S_1, for example, as the concentration which gives a partial maximum rate ($[S_2] \rightarrow \infty$) equal to half the true maximum rate, $V([S_1],[S_2] \rightarrow \infty)$. The initial rate equations derived for three main types of mechanism postulated for such reactions are then most closely analogous to that for a single substrate reaction. The equation:

$$\frac{e}{v_0} = \frac{1}{V} + \frac{K_{m_1}}{V[S_1]} + \frac{K_{m_2}}{V[S_2]} + \frac{K_{m_2}K_{s_1}}{V[S_1]\,[S_2]} \qquad (1)$$

has been derived for two types of mechanism, discussed in detail elsewhere[11,12]. Briefly, they are: (1) an alternative pathway mechanism in which binary complexes of each substrate with the enzyme, and a ternary complex, are assumed to be in equilibrium with the free substrates; (2) compulsory order mechanisms in which only one substrate (or coenzyme) forms a binary complex.

For mechanism (1), the Michaelis constants defined as here are equal to the dissociation constants of the *ternary* complexes, for example, K_{m_1} is the dissociation constant for $ES_1S_2 \rightleftharpoons ES_2 + S_1$, and may be greater or smaller than K_{s_1}, the dissociation constant for $ES_1 \rightleftharpoons E + S_1$. Moreover, the ratios K_{m_1}/K_{s_1} and K_{m_2}/K_{s_2} must be equal, because of the thermodynamic relation between these four equilibrium constants. (The case in which the ratio is unity, that is the combination of the enzyme with one substrate does not affect its affinity for the other, can be distinguished experimentally by a relationship between the initial rate parameters[12].)

For mechanisms of type (2), the Michaelis constant is a function of rate constants for reactions which do not involve either the free or bound substrate, and does not have any simple physical significance in general. The simplest is the Theorell–Chance mechanism[10], in which ternary complexes are either not formed or are not rate-limiting[12].

$$E + S_1 \underset{k_{-1}}{\overset{k_{+1}}{\rightleftharpoons}} ES_1$$

$$ES_1 + S_2 \underset{k_{-2}}{\overset{k_{+2}}{\rightleftharpoons}} ES_1' + S_2'$$

$$ES_1' \underset{k_{-3}}{\overset{k_{+3}}{\rightleftharpoons}} E + S_1'$$

For S_1, the leading substrate, or coenzyme, in the forward reaction, $K_m = k_{+3}/k_{+1}$ and therefore $K_m/K_s = k_{+3}/k_{-1}$. The corresponding quantities for S_1', in the reverse reaction, are the reciprocal ratios, k_{+1}/k_{+3} and k_{-1}/k_{+3}. Thus, the Michaelis constants and substrate constants will be equal only if the rates of dissociation of the reactant and product enzyme complexes are equal; and if $K_m > K_s$ in one direction, the reverse must be true in the reverse reaction. This is illustrated by experimental data for liver alcohol dehydrogenase: at *p*H 6·0, the Michaelis constants for nicotinamide-adenine dinucleotide (NAD) and NADH are 4·1 μM and 14 μM respectively[13], and the dissociation constants for the compounds of the coenzymes with the enzyme are 266 μM and 0·22 μM respectively[14].

If one or more rate-limiting ternary complexes are included in the foregoing reaction scheme, it can be shown[12] that for S_1, $K_m < k_{+3}/k_{+1}$. In general, with this type of mechanism, if the specific rate of dissociation of the product complex is smaller than that of the leading substrate complex, the dissociation constant for the latter will be greater than the Michaelis constant, as in the case of a single substrate reaction.

The third type of mechanism for two-substrate reactions is that in which the enzyme reacts with each substrate in turn, via a binary complex, to form a product, and itself undergoes intermediate chemical change by oxidation or reduction or group transfer[11,12]. The initial rate equation is:

$$\frac{e}{v_0} = \frac{1}{V} + \frac{K_{m_1}}{V[S_1]} + \frac{K_{m_2}}{V[S_2]} \qquad (2)$$

Again it can be shown that the relative values of K_m and K_s for each substrate depend on the relative rates of dissociation of the two binary enzyme–

substrate complexes. If $K_m > K_s$ for the substrate which reacts with one form of the enzyme, the reverse must be true in the reverse reaction for the substrate which reacts with the same form of the enzyme.

It has been shown[15,16] that competitive inhibitors present as impurities in coenzymes have quite different effects on initial rate parameters according to the relative values of K_m and K_s for the coenzyme. It may also be worth pointing out that, in a two-substrate reaction, a concentration of one substrate much greater than its Michaelis constant is not necessarily sufficient to ensure that the system becomes kinetically equivalent to a single substrate reaction. For example, in equation (1), if $[S_1] \gg K_{m_1}$ the second term will be negligible, but the last term may not be if $K_{s_1} > K_{m_1}$. This is of importance in kinetic studies of inhibition in such systems.

Production of Staphylococcal Coagulase in Stirred and Aerated Culture

AN interest in possible production methods for staphylococcal coagulase made us consider whether a submerged culture technique could be developed for this purpose since experience in these laboratories with diphtheria toxin production[1] had shown submerged culture to be a convenient and rapid method with many advantages over the older techniques of static culture. Submerged culture of coagulase had been attempted by Duthie and Haughton[2], who used the vortex system of aeration[3], but they had found only small yields of coagulase. On the other hand, Davies[4] had found that aeration of his cultures improved the coagulase yield, and Fahlberg and Marston[5] found an increase in coagulase production in shaken flasks as compared with unshaken flasks. It appeared therefore that, by a suitable choice of conditions, good yields of coagulase might be obtained in stirred aerated culture and small-scale experiments were started.

We used as a fermenter a 7-lb. Kilner jar, fitted with a metal top, which carried a rotating seal and a guide for the stirrer shaft. The top had an opening for inoculating and sampling and an air inlet and outlet. The impeller was a conventional turbo-mixer, 1/3 of the diameter of the tank, and was driven at 1,425 r.p.m. 1·75 l. medium were added to the jar which was standing in a constant-temperature water-bath at 35° C. Air was passed over the liquid at 200 ml./min and 25 per cent 'Antifoam *A*' (Midland Silicones, Ltd.) in butyl acetate was added as required. The organism used was *Staphylococcus aureus 5R* (*CN* 4575 in the Wellcome Bacterial Collection); this strain was known to produce high titres of coagulase when grown in the rough form[6]. It was also known to produce γ-lysin[7]. The inoculum was prepared by picking rough colonies from a chocolate agar plate and growing these in a baffled shake flask containing 100 ml. medium. The flask was shaken for 24 h on a rotary shaker (120 r.p.m. 3/4 in. throw) in an incubator at 35° C. 0·1 ml. of the resultant culture was used as an inoculum for the Kilner jar. Coagulase was measured by a modification of the method of Rammelkamp *et al.*[8] and titres are expressed as reciprocals of the highest dilutions causing clots. γ-lysin titres are reciprocals of the highest dilutions showing lysis of rabbit red blood cells.

Two media were used in this work; the first was nutrient broth which was sterilized by autoclaving. Using this medium growth and coagulase production were complete 28 h after inoculation, a coagulase titre of 3,200 was found and this was not altered after a further 18 h. The organisms did not appear to back mutate to the smooth type, all colonies arising from samples plated on chocolate agar being rough. The disadvantage of using this medium was the production of γ-lysin, titres of up to 64 occurring; it was therefore decided to try a different medium to see if this could be avoided. The medium selected was based on a papain digest of beef[9]. It was sterilized by filtration and had a final *p*H of 8·4. The first experiments using this medium were not encouraging. Growth was good, but 24 h after inoculation only low titres of coagulase were present. Further investigation, however, showed that high values could be obtained provided that growth was stopped after about 8 h and that if this was not done there was rapid destruction of the already formed enzyme (Table 1).

The formation of γ-lysin was, however, negligible in the 8 h sample; thus it seemed worthwhile to attempt to produce coagulase using this method and typical results are given in Table 2.

Table 1

Exp. No.	Coagulase titre after: 6 h	8 h	10 h	12 h	14 h
CT 5	160	1,600	320	80	80

Table 2

Exp. No.		Coagulase titre after. 3 h	4 h	5 h	6 h	7 h	8 h	9 h	10 h
CT	7	64	256	256	1,024	1,024	3,200	ND	ND
	16	ND	4	8	16	320	640	1,280	320
	17	80	320	640	2,560	2,560	1,280	ND	ND
	22	40	160	160	1,280	1,280	ND	ND	ND
	28	16	64	320	640	2,560	ND	ND	ND
	29	4	8	32	320	640	2,560	ND	ND
	31	4	16	64	640	1,280	640	ND	ND
	39	8	16	128	640	1,280	2,560	ND	ND

Coagulase was produced rapidly in these cultures and over-incubation by as little as an hour led to considerable destruction. The γ-lysin titre never exceeded 4. Since coagulase assay required 3 h it would be necessary to use a more rapid assay (see, for example, ref. 2) to determine the correct harvesting time. Exploratory work using aluminium tanks containing 11 l. medium has indicated that the scaling up of this process should not present any difficulty.

The reason for the rapid destruction of coagulase in these cultures has not been determined. It did not appear to be mechanical destruction since coagulase stirred in the absence of organisms remained stable, and addition of gelatin to cultures as a protective colloid did not prevent destruction. When 0·01 per cent 'Thiomersalate' was added to the organisms destruction ceased immediately and culture filtrates of organisms were not active in destroying the enzyme. It seems, therefore, that it was the organisms which were destroying the enzyme and it is of interest to note that this phenomenon may explain the fact that Duthie and Haughton found only small amounts of coagulase when they attempted production by submerged culture.

We thank Dr. I. R. W. Lominski, Western Infirmary, Glasgow, for supplying *Staphylococcus aureus 5R*, and Mr. C. van Toller for assistance.

Malignolipin and Malignant Tumours

Kosaki *et al.*[1–3] have recently reported the isolation of a new specific phospholipid, malignolipin, from malignant human and experimental tumours. They have described its role as a promoter of carcinogenesis[4] and have claimed to have evolved a histological test for the identification of malignolipin[5] and a diagnostic test for cancer[6,7] based on the detection of this phospholipid in blood. Anti-malignolipin sera have been reported[8] to reduce the viability of Yoshida sarcoma cells *in vitro*. These results await confirmation from other laboratories. The following therefore represents an attempt at isolating malignolipin from malignant tumours.

The material used in the work reported here comprised two types of human tumours (human tumours were kindly supplied by Dr. M. V. Sirsat, Pathology Department, Tata Memorial Hospital, Bombay)—breast and œsophagus carcinomas; three types of experimental tumours—a transplantable mouse fibrosarcoma originally induced by Waravdekar and Randive[9] and maintained in Swiss mice, spontaneous and transplantable breast tumours carried in *C3H* (*Jax*) mice and a spontaneous reticulum cell sarcoma in golden hamsters; and normal mouse liver.

Each of the foregoing types of material was worked up in at least two separate experiments. The method of Kosaki *et al.*[2] was carefully followed in all its details for the isolation of malignolipin picrate.

All the solvents used for the extraction of malignolipin and the preparation of its picrate were previously purified by standard procedures. In each experiment, at least 12–15 g of the material were ground with 9 volumes of absolute ethanol. The alcohol extract was precipitated with acetone. The precipitate was filtered through a sintered glass funnel, dried and eluted with petroleum ether. This eluate was further precipitated with acetone, filtered through a sintered glass funnel, dried and finally eluted with benzene. The benzene extract was mixed with an equal volume of saturated solution of picric acid in benzene. The picrate formed was filtered through the sintered glass funnel, washed free of excess of picric acid with benzene and crystallized three times from dioxan/benzene (1 : 7). It was finally crystallized from acetone.

A lemon-yellow picrate melting at 258°–65° C was obtained from all the malignant tumours as well as from normal mouse liver. The mixed melting points of the picrate derived from these materials remained undepressed. The melting point of the picrate, however, was different from that quoted[3] for malignolipin picrate (123° C). Unlike the bluish-white fluorescence in the ultra-violet reported[3] for the crystals of malignolipin picrate, this compound (m.p. 258°–65° C) does not exhibit any fluorescence in the ultra-violet either in the solid state or in solution. It is readily soluble in water, ethanol, acetone and dioxan but sparingly soluble in benzene, petroleum ether and chloroform. It did not show the presence of sulphur, halogens and phosphorus by Lassaigne's test[10]. Phosphorus could not be detected in any of the picrates even by Lowry's micromethod[11]. Analysis of the picrate shows C, 28·7 per cent, and H, 2·5 per cent by combustion method and N, 22·5 per cent by Johnson's method[12].

Unidimensional ascending paper chromatography of the picrates in butanol/pyridine/water (8 : 2 : 1) at 28° C yielded two spots with R_F values 0·6 (I) and 0·26 (II). Spot (I) was identified as picric acid from its R_F value and absorption spectrum. It appears that the complex decomposed during chromatography. Similar decomposition of the picrates during chromatography has also been reported by other workers[13,14]. The spot (II) with R_F value 0·26, when eluted with water, has no absorption in the visible range but has a λ_{max} at 256 mμ. The picrate has no absorption in the ultra-violet, but in the visible region it has an absorption maximum at 360 mμ due to the picric acid part of the molecule.

In this investigation so far, I have been unable to isolate malignolipin picrate (m.p. 123° C) from as many as five different types of pathologically confirmed malignant tumours listed above. Instead, a non-specific picrate has been obtained; its properties are much different from those reported for malignolipin picrate.

Differences between Urinary Albumin and Serum Albumin

In the work reported here, the molecular size and the peptide patterns of the albumins found in normal urine were compared with those of serum albumin.

Urine obtained from normal subjects was dialysed against distilled water and concentrated by freeze drying. The dry powder was dissolved in 0·0175 M phosphate buffer at *p*H 6·3 and applied to columns of diethylaminoethyl cellulose (DEAE). After separation of the first fraction eluted with the starting buffer at *p*H 6·3[1], a linear concentration and *p*H gradient was applied to the cellulose column (0·0175→0·4 M phosphate; *p*H 6·3→5·2). The fractions eluted by the buffer between 0·3 and 0·4 M phosphate were pooled, dialysed and concentrated. The proteins were further fractionated on a block of 'Pevikon *C*–870' using a borate buffer of *p*H 8·6, μ 0·064. The extinction coefficient of fraction *A* (corresponding to area *A*, 10 and 11 cm from the origin, Fig. 1,*A*) $E^{1\%}_{1\text{cm}}$ was 11·0, a value considerably higher than that obtained for serum albumin, which was 5·32. This high value was presumably due to the presence of bound urinary components rather than to an increased concentration of aromatic amino-acid residues; dialysis of serum albumin against normal urine, followed by extensive dialysis against 0·15 M sodium chloride, gave a solution of serum albumin with an $E^{1\%}_{1\text{cm}}$ = 49.

Fig. 1,*C* shows the immunoelectrophoretic pattern obtained when fraction *A* and normal human serum were reacted with an antiserum prepared by the injection of a horse with normal human serum (Inst. Pasteur, Lot No. 13411). Fraction *A* gave a single precipitin line corresponding to a protein that was slightly more electronegative than serum albumin at *p*H 8·6. It also gave a reaction of complete identity with crystalline serum albumin when reacted with an antiserum albumin in two-dimensional agar gel diffusion plates (Fig. 1,*F*). It did not react with an antiserum prepared in a goat against human orosomucoid (Hyland Labs. Lot No. *GABS* 88).

Increasing dilutions of a known weight of fraction *A* and of a standard solution of crystalline serum albumin were titrated by gel diffusion (in an Ouchterlony plate) against a standard solution of the antialbumin antiserum. Using as the end-point the greatest dilution of antigen (serum albumin or fraction *A*) which gave a visible precipitin line with antiserum, such lines were not discernible with less than 9·3 μg of fraction *A* or 6·3 μg of serum albumin.

Ultracentrifugal analyses of 5 samples of fraction *A* from urines of different individuals each gave a single peak with an average sedimentation constant, $S_{w,20}$ of 2·6 ± 0·2 (uncorrected for protein concentration) as compared to $S_{w,20}$ 4·2 for crystalline serum albumin of comparable concentration.

Samples of urinary albumin and crystallized serum albumin were denatured at *p*H 8·0 by heating at 100° C for 45 min, then hydrolysed at *p*H 8·0 with chymotrypsin in the *p*H-stat[2] in an enzyme to substrate ratio of 1 : 8 and the peptides separated in two dimensions on No. 1 Whatman filter paper, first by high-voltage electrophoresis in one dimension followed by ascending chromatography in the second dimension as previously described[3]. The resulting peptide patterns are shown in Fig. 1,*D* and *E*. Although the 'albumins' obtained from urines of different individuals had similar mobilities in zone electrophoresis, some of them were found to be more electronegative than serum albumin at *p*H 8·6 when analysed by immunoelectrophoresis. Fig. 1,*D* shows a representative peptide pattern obtained with the more electronegative urinary albumin. A poor differentiation of spots was obtained on the peptide patterns when the more electropositive albumins were analysed. The urinary albumins that were more negatively charged at *p*H 8·6 gave patterns which had little or no resemblance to those obtained after digestion of serum albumin. Whether this difference is due either to a unique denaturation of urinary albumin following renal filtration or to a splitting of the peptide bonds *in vivo*

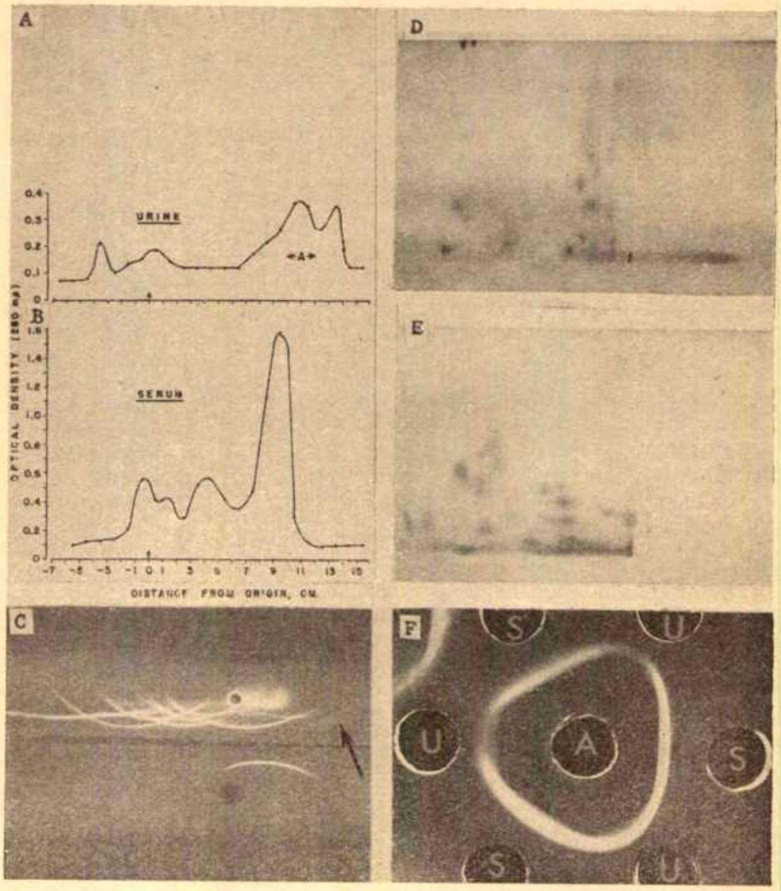

Fig. 1. Starch-block electrophoresis: pattern of urine (*A*) and serum (*B*). Immunoelectrophoresis (*C*) of the more electronegative (at *p*H 8·6) urinary albumin (lower well) and normal human serum (upper well). Centre trough contains horse anti-human serum. The precipitin line corresponding to serum albumin is marked by arrow. Representative peptide pattern of the urine albumin (*D*) and serum albumin (*E*). Ouchterlony plate (*F*) *U*, urine albumin; *S*, crystalline human serum albumin; *A*, anti-human serum albumin (horse)

with formation of smaller fragments held together by disulphide bonds is not known.

If serum albumin is re-absorbed by the tubules following glomerular filtration[4] it is interesting that at least some of these smaller molecules of albumin appear in the urine and presumably escape re-absorption.

Quantitative Analysis of Sugars in Royal Jelly

THE amount of carbohydrate in royal jelly, determined in terms of total reducing substances, has been investigated. The results are seen in tabular form in a review by Johansson[1] and show concentrations of carbohydrate in fresh royal jelly ranging from 8·3 to 29·1 per cent by weight. During one of these investigations[2] an additional test was conducted, which was based on selective fermentation procedures, whereby a sample of native royal jelly, having a total reducing-sugar concentration of 29·1 per cent (calculated in terms of glucose), was found to have an apparent glucose concentration of 12·2 per cent, a fructose concentration of 15·2 per cent and a concentration of 1·7 per cent for non-fermentable carbohydrates.

It has been determined that D-glucose, D-fructose, and D-sucrose are the principal sugars in royal jelly[3]; the results having been based on the isolation and identification of crystalline sugars and their derivatives. Working with a sample of royal jelly from the same source[4] as that used in the work just cited, the investigation now described is a quantitative analysis of the principal sugars in royal jelly, conducted using the methods of paper partition chromatography and quantitative colorimetric assay, following an established procedure[5]. This method of analysis, involving the fractionation of sugars prior to colorimetric quantitative analysis of each sugar, is believed to be more reliable than methods based on the fermentation or reducing characteristics of one sugar in the presence of others.

Standard curves for the sugars to be analysed were prepared in the following way. Standard solutions of D-glucose, D-fructose and D-sucrose were prepared and aliquots of each, analysed in triplicate, ranging in concentration from 5 to 30 μg of sugar per ml. of solution, were transferred to matched colorimeter tubes. Aqueous phenol (0·100 ml. of 80 per cent w/w) and sulphuric acid (5·00 ml. of 36 normal) were added and the contents of the tubes carefully mixed, stoppered lightly, and then allowed to cool for 0·5 h. Absorbances of the yellow-orange solutions were determined with a 'Spectronic 20' spectrophotometer at a wave-length setting of 490 mμ. The absorption data for the three sugars, after compensation with blank samples, are shown in Table 1. Standard curves for the sugars were then constructed as shown in Fig. 1.

Table 1. ABSORPTION DATA FOR D-GLUCOSE, D-FRUCTOSE AND D-SUCROSE (STANDARD SOLUTIONS)

Compound	Concentration (μg/ml.)	Absorbance Per sample	Absorbance Average
D-Glucose	7·8	0·102	0·101
		0·102	
		0·098

In order to separate and analyse the sugars in royal jelly, an aliquot portion (20–30 mg) of royal jelly, weighed by difference using a micropipette, was placed on the 'starting line' of Whatman No. 1 chromatography paper (18¼ in. × 22½ in.). The sugars were subjected to partition in the usual way[3,5,6], using *n*-butanol/ethanol/water (4 : 1 : 5, upper layer) as the irrigating solvent, during a 24-h period. By cutting small strips from the paper and spraying these strips with Tollens reagent according to a method described in a previous paper[3], the positions of the sugars on the chromatography paper were determined. Using this solvent the sugars were differentiated from each other by relating their R_F values to those of D-glucose (R_F, 0·16), D-fructose (R_F, 0·19), and D-sucrose (R_F, 0·03).

After eluting the sugars from the paper with water (20·00 ml., 15 min) the solutions were filtered through glass wool and aliquot portions (1·00 ml.) transferred (in triplicate) to matched colorimeter tubes. Blank samples were prepared by cutting from the chromatogram segments of paper which held no sugars, but which were equal in area to those segments from which sugars were eluted. Thus, each sugar fraction separated from the paper had a corresponding blank fraction. These blank segments were washed in water (20·00 ml., 15 min) and the extracts filtered through glass wool.

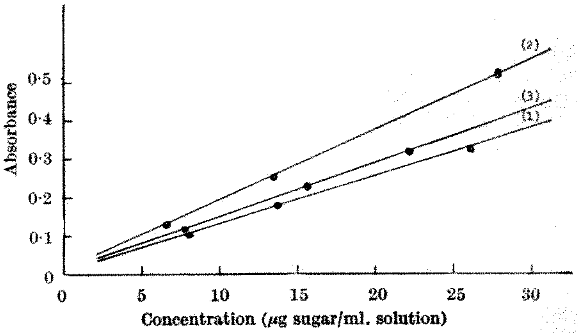

Fig. 1. Standard curves. 1, D-Glucose; 2, D-fructose; 3, D-sucrose

Aliquot portions (1·00 ml.) were transferred (in triplicate) to matched colorimeter tubes. Aqueous phenol (0·100 ml. of 80 per cent w/w) and sulphuric acid (5·00 ml. of 36 normal) were added to all sugar and blank samples. The contents of the tubes were carefully mixed and were then stoppered lightly and allowed to cool. After 30 min the absorbances of the solutions were determined using a 'Spectronic 20' spectrophotometer set at 490 mμ. Average values were determined and referred to the standard curve for each particular sugar, after compensating for the corresponding blank values. The concentration of each sugar in royal jelly was thereby determined; the results of three independent analyses are shown in Table 2. Based on an average of the three analyses, as shown in Table 2, the royal jelly sample which was analysed contained (per cent by weight) 9·76 D-glucose, 11·32 D-fructose and 0·94 D-sucrose.

Table 2. ANALYSIS OF SUGARS IN ROYAL JELLY
Concentration (% w/w) of sugars in royal jelly

	Trial No. 1	2	3	Average value
D-Glucose	9·82	9·77	9·66	9·76
D-Fructose	11·29	11·31	11·35	11·32
D-Sucrose	0·91	0·92	0·99	0·94

Effect of Urea on the Synthesis of Polynucleotides with Crude Bacterial Extracts

A CRUDE bacterial extract is normally not capable of catalysing a net synthesis of poly-A from ADP[1]. If, however, the myokinase-like enzymes are blocked by the addition of ATP one observes a considerable net synthesis of polynucleotides with crude extracts of *Azotobacter vinelandii*, as we have found recently[2,3]. In this way the degradation of ADP, which leads to nucleosides and nucleobases via AMP, is inhibited. A complete inhibition of the adenylate kinase occurs if the ratio of ATP/ADP is 1 : 1 or higher; at lower ratios only an incomplete inhibition of the adenylate kinase and correspondingly a lower net synthesis of polynucleotide is observed. The amount of poly-A decreases after several hours because of phosphorolysis (Fig. 1).

We have now found that this phosphorolytic splitting of the polymer can be inhibited by adding 0·4 M urea. The course of the reactions is illustrated in Fig. 1.

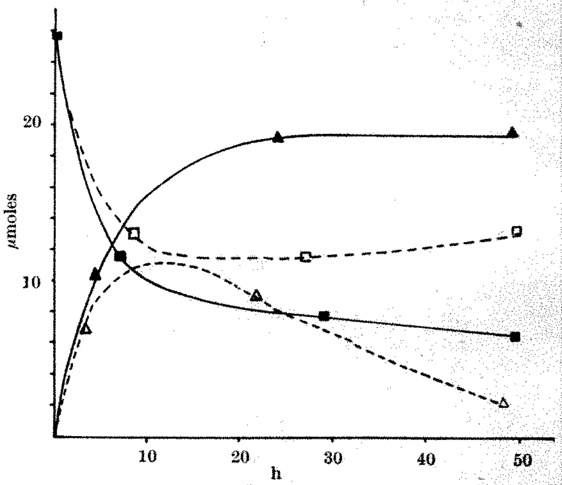

Fig. 1. Course of poly-A synthesis from ADP with a crude extract of *Azotobacter vinelandii*: 25 μmoles of ADP, 6 μmoles of ATP, 10 μmoles of magnesium chloride, 200 μmoles of *tris* buffer (*p*H 8·1), crude extract from *Azotobacter* containing 1·0 mg protein. Final volume 1·0 ml, temperature 30°. △, poly-A; □, sum of ADP + ATP without addition of urea; ▲, poly-A; ■, sum of ADP + ATP in the presence of 0·4 M urea

A. vinelandii was grown according to Hyndman *et al.*[4]. 23-g portions of wet bacteria were homogenized in 46 ml. of distilled water by means of a 'Zellhomogenisator' (Braun, Melsungen, Germany) with glass balls (0·11–0·12 mm) for 120 sec under cooling with carbon dioxide. The resulting suspension was sucked through a cool glass filter and centrifuged at 20,000*g* at 0° for 1 h. The supernatant liquid was frozen and kept at – 18°; it was directly used for the experiments. Protein was determined by the biuret method. Phosphate exchange was assayed according to Grunberg-Manago *et al.*[5]. The crude extracts had average specific activities of 0·5 unit/mg protein.

The course of the reactions was examined by means of paper chromatography. 1 per cent ammonium sulphate / isopropanol (1 : 2)[6] was used as the solvent. For quantitative analysis the spots, which had been located by means of a short-wave ultra-violet lamp, were cut out separately and eluted with 4·0 ml. of 0·05 M *tris* buffer (*p*H 7·0) for 15–20 h. Extinction coefficients used:

$$\varepsilon_1(\text{for ADP and ATP}) = 15{\cdot}78 \times 10^3;\ \lambda_{\max} = 259\ \text{m}\mu^7.$$

$$\varepsilon_2\ (\text{for poly-A}) = 9{\cdot}8 \times 10^3;\lambda_{\max} = 257\ \text{m}\mu^8.$$

A corresponding paper blank was subtracted.

The identity of the poly-A was proved by means of alkaline degradation, which resulted in a mixture of 2′- and 3′-AMP, and also through the examination of the ultra-violet spectrum[8]. The reaction product could not be dialysed. In paper chromatography and in cellulose layer chromatography[9] it remained at the origin of the chromatograms.

In the presence of urea, part of ATP is also used up indirectly for poly-A synthesis through the myokinase equilibrium. We do not, however, believe that in this case ATP is a direct substrate of the enzymatic polycondensation. This opinion is also supported by experiments in which ATP alone was incubated with the crude extract. Here a net synthesis of poly-A only started after ADP had been added. We therefore presume that ADP is the substrate of the reaction and that the enzyme in question is polynucleotide phosphorylase[5].

The effect of urea can also be used in the preparative synthesis of polynucleotides. 2·86 m.moles of ADP, 0·89 m.mole of ATP, 1·0 m.mole of magnesium chloride, 20 m.moles of *tris* buffer (*p*H 8·1) and crude extract of *A. vinelandii* (containing 100 mg protein) were made up with water to 100 ml. Urea was added to give a final concentration of 0·4 M. The solution was kept at 30° for 32 h, and the poly-A isolated according to Olmsted *et al.*[10]. The yield was 1·46 m.moles of poly-A (51 per cent). [*Note added in proof.* The molecular weight of the product was measured ($S^0_{20} = 2{\cdot}55$; corresponding molecular weight $= 3{\cdot}1 \times 10^4$) by H. Seidel and R. Iyanger.]

We cannot yet give a full explanation of the effect of urea. Urea might act as a competitive inhibitor[11]. The other possibility is that through the presence of urea the secondary structure of the poly-A chain might be changed in such a way that it can no more be attacked by the enzyme.

Treatment of Sub-cellular Particles prior to Assay of the Enzymatic Marker, Succinic Dehydrogenase

IT is very useful to be able to pin-point the activity of a tissue enzyme in a morphologically distinct sub-cellular unit, and this is frequently attempted by measuring the activity of the enzyme in fractions or sub-fractions obtained by centrifuging tissue homogenates. Succinic dehydrogenase is generally accepted and frequently used as an enzymatic marker for mitochondria in fractionation studies. It appears, however, that it is difficult to recover 100 per cent of the activity of succinic dehydrogenase of a homogenate after fractionation, particularly after centrifugation of particles in gradients of dense sucrose[1–8], and the hopeful assumption has been made that the distribution of the recovered activity (ranging from 52 to 136 per cent) accurately reflects the true distribution (that is, that the errors or losses of activity are uniformly spread among the fractions). Experience has shown that this assumption can be far from the truth.

100 per cent recovery of activity is necessary in meaningful distribution studies and is usually, though not necessarily, achieved most easily when each fraction sample is made to show the maximum activity of which it is capable with the chosen assay system. For fractions obtained from brain homogenates by centrifuging in 0·3 M sucrose, suspension of the sedimented particles in water or very hypotonic buffer for an hour before assay was found to be a sufficient pre-treatment to produce maximum activity with a consequent high recovery of homogenate activity in the fractions[3]. It was presumed that the pre-treatment effectively reduced a limiting permeability barrier by osmotic swelling. However, this pre-treatment was not so successful with sub-cellular particles which had been centrifuged through high concentrations of sucrose or of Ficoll polymer in 0·3 M sucrose[2,4], nor do experimental conditions always permit the particles to be sedimented and resuspended in a medium of low tonicity prior to assay. This note describes an improvement in the treatment of sub-cellular fractions before succinic dehydrogenase assay such that good recoveries and nearly maximum activities are measured even after density gradient separation and even if the tonicity of the pretreatment medium cannot be reduced very far. By this procedure, recovery of succinic dehydrogenase activity among the *A*, *B* and *C* sub-fractions of a brain P_2 ('mitochondrial') fraction prepared by a modification of the method of Gray and Whittaker[9,10] was 96 ± 3 per cent (4 experiments).

The improved pretreatment is as follows: The suspended particles are diluted to a suitable volume with 3–10 mM phosphate buffer (ammonium or potassium), preferably containing 4 mM sodium succinate, and stored at 0° for 1–2 h. The suspension is frozen to − 20° or lower in a stoppered 'Pyrex' tube. It may be stored overnight in this state or else thawed after 20 min. The thawed suspension is kept at 0° for at least a further hour before assay. For the comparisons in Table 1, brain mitochondria were either suspended in mildly hypotonic sucrose (0·1 M) containing 10 mM ammonium phosphate buffer *p*H 7·4 (sample *A*), or were suspended in 5 mM potassium phosphate buffer *p*H 7·4 after they had been sedimented by centrifuging for 90 min at 75,000*g* in 1·1 M sucrose (sample *B*). Addition of 1–4 mM ethylenediamine tetraacetic acid to the suspension medium had little effect, but inclusion of magnesium chloride was deleterious. Inclusion of succinate seemed to increase the activity little, but sample activity was generally preserved for a longer period in its presence. Assay of activity of succinic dehydrogenase was by the manometric method of Aldridge and Johnson[3] using a hypotonic medium with ferricyanide as electron acceptor. This acceptor is suitable for assay of the particulate succinic dehydrogenase complex[11,12] and is preferred here over phenazine methosulphate both for its sensitivity and for the fact that a linear rate of carbon dioxide evolution is maintained throughout a 45-min assay enabling more accurate determinations to be made than with the latter acceptor which permits very brief assays only. The activities are recorded in Table 1 as percentages of that measured after the improved standard pre-treatment described here.

The results in Table 1 show that a freeze/thaw cycle applied to swollen particles was the best pre-treatment. A freeze/thaw cycle applied to particles suspended in 0·3 M sucrose raised the apparent activity from 35 to 84 per cent so the freezing is not

Table 1. COMPARISON OF PRE-TREATMENTS OF BRAIN MITOCHONDRIAL SUSPENSIONS BEFORE SUCCINIC DEHYDROGENASE ASSAY

	Pre-treatment	Sample *A*	Sample *B*
(*a*)	Stand 0°/15 min		
(*b*)	Stand 0°/1 h (unbuffered)	48 (2)	
(*c*)	Stand 0°/2½–4½ h (unbuffered)	86 (4)	
(*d*)	Stand 0°/2 h	70 (4)	63 (3)
(*e*)	Nil; add 'Triton *X*-100' to assay medium in concentration listed (%)		
	(i) 0·04	38	
	(ii) 01	67	
	(iii) 0·2	45	
	(iv) 0·5	18	
(*f*)	Standard	100 (6)	100 (6)
(*g*)	Standard (unbuffered)	90 (3)	
(*h*)	As (*f*) but ultrasonics* instead of freeze/thaw	85 (4)	
(*i*)	As (*f*) but also add 'Triton *X*-100' (0·125%) to assay medium	89	

* 90 sec (optimal) ultrasonic treatment at 20 kc/s

Succinate was not included in the pre-treatment media of these experiments. Numbers of determinations are noted in parentheses.

completely effective without some prior swelling of the particles. It should be noted that particles left in buffer suspension at 0° for periods of 5 h or more have been found to suffer loss of activity. The failure of ultrasonic treatment to produce full activity did not appear to be due to inactivation of the enzyme since a further 30-sec treatment did not lower the activity. The effect of increasing amounts of 'Triton *X*-100' is not surprising since the ferricyanide acceptor is not suitable when the particulate succinic dehydrogenase complex is disintegrated by various solubilizing treatments[12].

For some tissue preparations, a simple pre-treatment with calcium ions (0·75 mM) without freezing and thawing seems sufficient to obtain full activity using phenazine methosulphate as electron acceptor, but this was inadequate when applied to brain mitochondria[5]. The method described here has not been tested on a wide variety of tissues, but gives satisfactory results with liver and muscle fractions besides those from brain.

Iso-Butyric Acid in Silage

The presence of iso-butyric acid in silage has not been reported since Klinc[1], using a qualitative chemical method of detection, claimed to have found it in the material in the surface layers of a silo. Barnett[2] during comprehensive investigations into the formation of the volatile fatty acids in silage found no trace of it, but the results of Lessard, Briggs and Scaletti[3] suggest its presence in samples of alfalfa silage made in the laboratory. No quantitative determinations of the acid have been reported.

In the course of the determination of the volatile fatty acids present in 400 samples of silage, in this Department, iso-butyric acid has been found in measurable amounts in 38 of them. The silages were made from grass, or grass and clover mixtures, and were taken from farms in the south-east of England in the winter of 1961–62. The levels of the acid found were low with an average value of 0·35 mg/ml. in the silage juice, or 0·13 per cent when calculated to a dry matter basis. The iso-butyric acid occurred in the same range of silage *p*H as the *n*-butyric acid, but it made up only a very small proportion of the total butyric acid present. Table 1 shows the *p*H-range in which the iso-acid occurred, and also the substantial proportion of the total number of samples in the range which contained it.

These results suggest that iso-butyric acid occurs widely in small amounts probably as the result of secondary fermentation processes in the silage. Its distribution in samples, therefore, might be expected to be even more widespread in winters following poor silage-making seasons.

Table 1

	*p*H			
	4·0–4·5	4·6–5·0	5·1–5·5	5·5–6·0
No. of samples containing iso-butyric acid	6	6	23	3
Percentage of total samples containing iso-butyric acid	4·9	13·0	57·5	42·6

The method used for the separation and determination of the volatile fatty acids in this work was based on a gas-liquid chromatography technique. The acids were steam distilled from a sample of the silage juice, extracted by means of ether and injected directly on to the column. The column was 8½ ft. long with a stationary phase of silicone 550 containing 12 per cent behenic acid coated on to 100–120 mesh 'Celite 545'. Nitrogen was used as the carrier gas and the temperature of the column was 135° C. The acids were detected by automatic titration with N/100 sodium hydroxide.

Production of Humic Substances in Decomposing Peat and Compost Samples

During an investigation into the physical properties of humic acids, humic products were extracted from mixtures of papyrus and various additives such as different types of clays, which had been decomposing in natural tropical swamps for periods of up to 20 months, and from core samples collected from deep

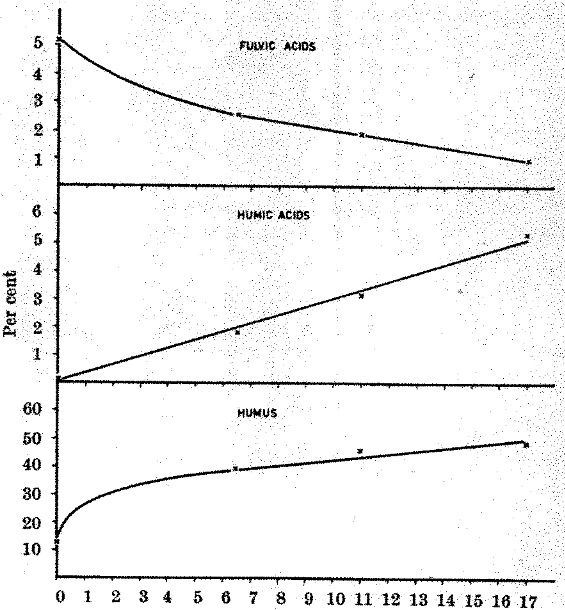

Fig. 1. Changes in the concentrations of the humic products in decomposing papyrus samples

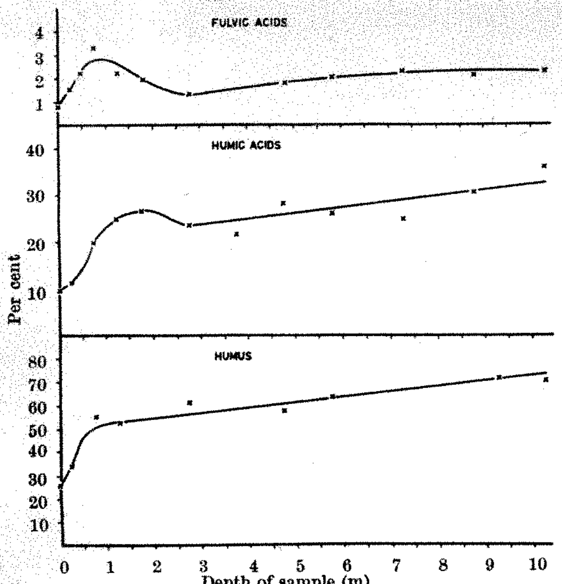

Fig. 2. Changes with depth in the concentration of the humic products in sphagnum peat

papyrus and sphagnum peat deposits (down to 20 m), by which the time-scale for the period of decomposition could be extended to durations exceeding 15,000 years.

It appeared (Figs. 1 and 2) that with progressing decomposition (and hence with older peat and compost samples) there were proportional increases in the contents of humic acids (extracted with 0·5 per cent sodium hydroxide and purified by reprecipitation in sodium hydroxide/hydrochloric acid) and humus (as the organic residue which was insoluble in acetyl-bromide).

It was found that the percentage of the coloured components of the fulvic acid fraction (estimated as the insoluble barium salts at *p*H 7·0 of the organic material soluble in the range *p*H 2·0–10·0)[1] could be used as an indicator of the speed of the decomposition process: if this had been fast, then the production of these acids greatly exceeded their polymerization, condensation or breakdown. Values were reached of up to 13 per cent for very rapidly decomposing samples, while for samples decomposing at a normal rate at the time of sampling, the fulvic acid content was consistently lower than 2 per cent.

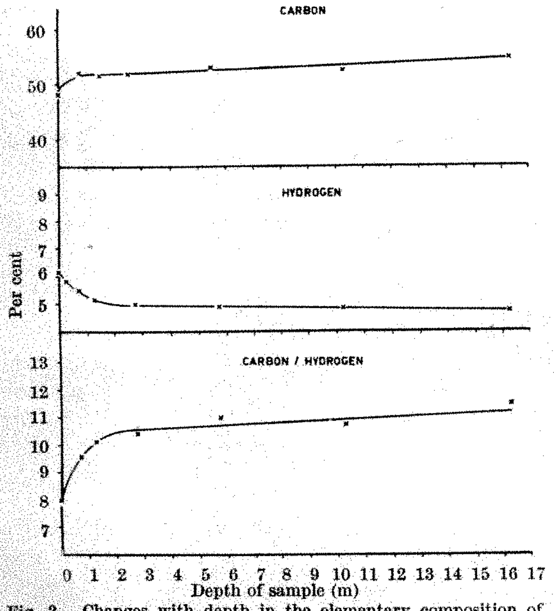

Fig. 3. Changes with depth in the elementary composition of the humic acids from a sphagnum peat

For the determination of the rate and course of the decomposition process previous to and at the time of sampling, several ratios of the humic products also proved to be of importance. The ratio fulvic acids/humic acids, for example, proved to be particularly high (1–40) in fresh and still actively decomposing material, while the ratio fulvic acids/humus was very low (< 0·05) in material which had actively decomposed in the past, but where the rate of decomposition had since slowed down.

For the core samples changes in these ratios with depth could also be well correlated with changes in the vegetation (as shown by pollen analysis) which contributed to the formation of the deposit layer.

The humic acids, with regard to elementary analyses, had a very different composition from what was previously recorded in the literature[2]. The carbon contents (34–55 per cent) were lower than the values which had hitherto been accepted as valid for these acids (55–60 per cent), and most of the percentages of hydrogen (5–11 per cent) and oxygen (40–55 per cent), on the other hand, were higher than had been expected (respectively 3–5 and 30–40 per cent).

As the carbon contents and the carbon/hydrogen ratios increased with progressing humification, and the percentages of hydrogen decreased (Fig. 3), it therefore seems likely that the humic products investigated, even those extracted from the deepest core samples (more than 16 m in depth and more than 15,000 years in age), are less humified than the more recently formed humic acids obtained by other investigators.

Table 1. AMOUNTS OF HUMIC PRODUCTS FORMED AFTER DECOMPOSITION OF PAPYRUS FOR 20 MONTHS UNDER VARIOUS CONDITIONS AND THE ELEMENTARY ANALYSIS OF THE HUMIC ACIDS

	Aerobic decomposition	Anaerobic decomposition	Anaerobic decomposition with kaolinite	Anaerobic decomposition with montmorillonite
Fulvic acids (%)	0·52	0·60	1·53	2·60
Humic acids (%)	0·13	0·27	2·07	1·27
Humus (%)	12·5	27·2	55·5	12·00
Elementary analysis of humic acids				
Carbon (%)	38·96	40·33	37·73	47·82
Hydrogen (%)	5·62	4·79	7·36	4·86
Oxygen (%)	53·65	53·21	52·50	41·40
Nitrogen (%)	1·77	1·67	2·41	5·92

It was also found (Table 1) that, in contrast with montmorillonitic clays, the presence of kaolinite results in a more rapid breakdown but in a less-advanced humification; therefore, although fewer humic acids are produced in the presence of montmorillonite, they are more humified.

It followed from most analyses that anaerobic or semi-aerobic conditions are more favourable for decomposition and humification than are aerobic ones. Indications were obtained that alternating anaerobic and aerobic conditions would be even more favourable.

Effect of Pyridoxal 5-Phosphate in the Presence of Vanadyl Ions on the De-iodination of Thyroxine

In the course of a recent investigation of the effects of metal ions on the de-iodination of thyroxine, it was suggested that sulphydryl groups are involved in the regulatory mechanism of de-iodination on the cellular level[1,2].

Pyridoxal 5-phosphate has been shown to induce *in vitro* in the presence of certain cations, for example, vanadyl or aluminium, the catabolism of sulphydryl-carrying amino-acids[3-5]. It was of interest to check whether the pyridoxal phosphate–vanadium complex can affect the rate of deiodination *in vivo*.

Groups of 10 mice of local strain were used. 0·1 ml. of the investigated material in saline solution was injected intraperitoneally. One hour after injection, the mice were injected with thyroxine labelled with iodine-131. Two hours later, the mice were killed and the amounts of labelled protein-bound iodine and of iodide in serum were determined as follows: the serum proteins were precipitated by trichloroacetic acid (TCA), in the presence of iodide hold-back carrier, and centrifuged. Then the supernatant and washings were collected and the iodide was precipitated with 1 M silver nitrate. The labelled protein-bound iodine and the labelled silver iodide were counted, and the ratio of $^{131}I/^{131}PBI + ^{131}I$ was calculated. This ratio increases when de-iodination is enhanced.

Oxygen consumption-rate was also determined and the procedure adapted was as follows: the measuring system consisted of an Erlenmeyer flask of 1,200 ml. which was attached to a differential manometer filled with a silicon fluid (density 1·10). A known volume (100 ml.) of soda-lime inside a meshed container was introduced into the flask. Air-flow through the flask could be controlled by a stopcock. The measurements were carried out in a thermostat at 22 ± 0·5° C using three mice at a time, the weight of which was determined. Before each measurement, air was passed through the flask for a few minutes, the stopcock was then closed, and the change in pressure was followed by the differential manometer.

The results given in Table 1 show that whereas pyridoxal phosphate alone has no effect on the rate of de-iodination, vanadyl ions have a certain effect of enhancement. However, when vanadyl ions are administered simultaneously with pyridoxal 5-phosphate, the catalytic effect of vanadyl ions is doubled. It can be further seen from Table 1 that the oxygen consumption-rate diminishes as the rate of de-iodination increases.

The effect of thyroxine on pyridoxal phosphate-level in liver[6,7] and the effect of the latter compound on the deamination of thyroxine[8] have been reported. Our observation is, however, of a different phenomenon, namely, an effect on the rate of thyroxine de-iodination. The fact that pyridoxal phosphate alone has no effect on thyroxine metabolism shows that, within the short time of our experiments, there is no interference with the different modes of action of pyridoxal phosphate. The activation of pyridoxal by vanadyl ions is rather specific to alpha-beta elimination[3,9] and strongly suggests that it decreases the level of sulphydryl groups in the organism.

The results corroborate our former observations[2] that sulphydryl groups are involved in the process of de-iodination and that this process is not parallel to but reciprocal with the oxygen consumption-rate.

Table 1. EFFECT OF PYRIDOXAL 5-PHOSPHATE IN THE PRESENCE OF VANADIUM ON THE RATE OF DE-IODINATION OF THYROXINE AND ON RATE OF OXYGEN CONSUMPTION

Compound	Dose per mouse (mg)	$^{131}I/^{131}PBI + ^{131}I$ (× 100)	Difference (%)	*S.D.*	Oxygen consumption rate (ml. O_2/min/g)	Difference (%)
Controls	—	3·0 ± 0·28	—	—	0·065	—

PHYSIOLOGY

Effect of Cortisone on the Urinary Excretion of Histamine in the Hyperthyroid Rat

Recent work has emphasized that histamine metabolism in the rat may be influenced by adreno-cortical[1,2] and thyroid[3,4] hormones. Various observations also indicate that these two groups of hormones may be functionally related in certain respects. It was therefore of interest to examine the action of cortisone on the urinary excretion of histamine in the hyperthyroid rat. It has been shown[3] that the rat treated with thyroxine has a high urinary histamine-level, and there is evidence that the high urinary histamine is the result of an increased rate of histamine synthesis[4].

The urine of female, non-pregnant Sprague–Dawley rats (initial body-weight about 150 g) was collected in 24-h portions under hydrochloric acid. The rats were given 10 g of a semi-synthetic, histamine-free food. The free urinary histamine (μg histamine base per 24 h) was determined by bioassay on the ileum of guinea pigs[2]. All rats were given aminoguanidine to prevent inactivation of histamine by histaminase[4] (diamine oxidase).

Liothyronine was given subcutaneously in a dose of 0·05 mg/rat/day. Cortisone was given intramuscu-

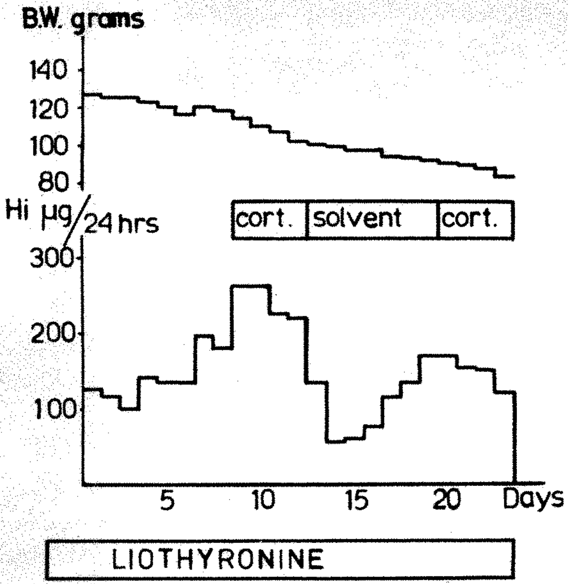

Fig. 1. Changes in urinary histamine μg base per 24 h (lower diagram) and body-weight in g (upper diagram) in response to continuous treatment with liothyronine (0·05 mg daily) and intermittent administration of cortisone (5 mg daily). Liothyronine was given 2 days before starting urine collection. The rat received aminoguanidine 20 mg/kg subcutaneously once daily

larly in a dose of 5 mg/rat/day. As controls the respective solvents were injected.

The previous observation[4] of an increase in the urinary histamine-level in response to the prolonged administration of liothyronine was confirmed. The increase started after 4–5 days of treatment. It may be seen from Fig. 1 that the administration of cortisone for 4 days brought the urinary histamine of the hyperthyroid rat down to a normal level, from which it rose again, when only the cortisone solvent was injected. On renewal of cortisone treatment the urinary excretion of histamine was again reduced.

It was also found that liothyronine, when given to a cortisone-treated rat, did not raise the urinary histamine as it did in control animals given the cortisone solvent.

Apparently, cortisone can both prevent and abolish the increase in urinary histamine brought about by liothyronine in the rat. A direct antagonism between cortisone and liothyronine as regards histamine metabolism is thus likely. The results may help to explain the finding of Spencer and West[6] that cortisone normalizes the increased sensitivity to histamine of the hyperthyroid mouse. The enhanced sensitivity to histamine of hyperthyroid animals may well be caused by an accelerated rate of endogenous synthesis of the amine. A similar mechanism may explain the high sensitivity to histamine of the adrenalectomized rat and of animals treated with haemophilus pertussis vaccine[7].

It is still too early to say whether hyperthyroidism in man and the beneficial effects of adrenocortical steroids in hyperthyroid crises[5] may involve changes in the metabolism of histamine.

Immuno-electrophoretic Demonstration of Differences in Serum Proteins of New-born Infants of Normal and Diabetic Mothers

In a previous communication we reported that newborn infants of diabetic mothers have raised serum glycoprotein-levels when compared with infants of normal mothers of similar gestational age[1]. In continuation of this investigation we have subjected the same sera to immuno-electrophoresis in agar gel, using a modification of Scheidegger's micro-method[2]. Commercially available anti-sera from the Pasteur Institute were used as a mixture from horses No. 223 and No. 224.

Sixteen diabetic infants and fourteen controls were examined. In the diabetic babies we found a pattern of serum proteins which was consistently and distinctly different from patterns of normal controls. Representative patterns observed in an infant of a normal and a diabetic mother are reproduced in Fig. 1. It can be seen that the infant of the diabetic mother, in comparison to its control, has a larger number of distinct arcs, of which that in continuation of the orosomucoid and that in the siderophilin region are most striking.

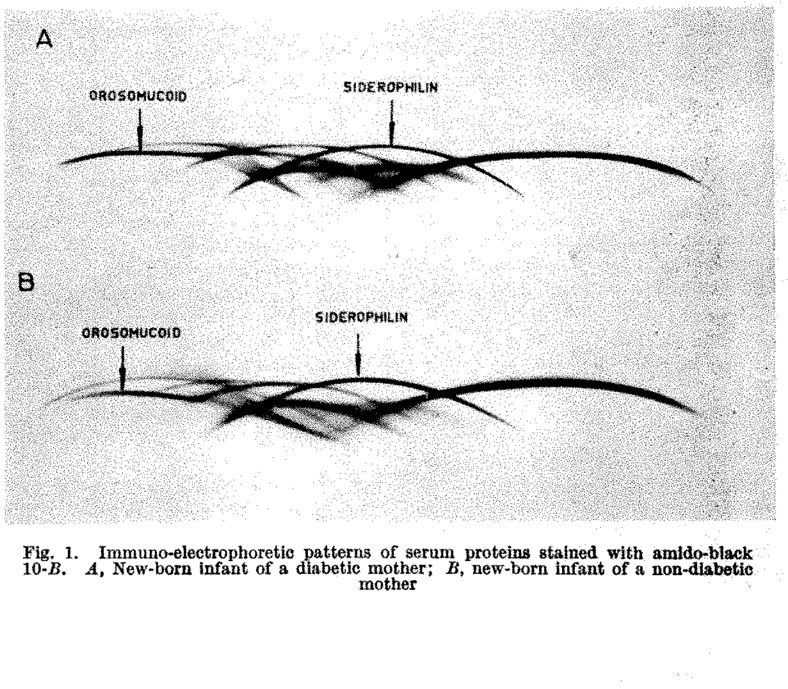

Fig. 1. Immuno-electrophoretic patterns of serum proteins stained with amido-black 10-*B*. *A*, New-born infant of a diabetic mother; *B*, new-born infant of a non-diabetic mother

ANATOMY

Extracellular Single Fibre Recording Technique for Peripheral Nerves without Section of Nerve or Incision of Perineurium

Two main techniques are at present in use to obtain electrophysiological data from single afferent fibres in mammalian and reptilian nerves. (1) The nerve trunk is severed and successively fractionated until the stage is reached at which a fine strand (or strands) gives a unit response. This method suffers from the disadvantage that the nerve trunk is severely damaged and only a few fibres can be investigated in each experiment—an inevitably non-representative sample of the nerve fibre (or receptor) spectrum. (2) A micro-electrode is inserted into the dorsal root or its ganglion, from which extra- or intra-cellular single unit recordings are made. In this case a representative sample of all dorsal root fibres can be taken, but it is impossible to obtain a true sample of the fibres supplying a particular area of skin. Several isolated reports also describe extracellular[1-5] and intracellular[6] records made with micro-electrodes inserted blindly into nerve trunks, but no generally applicable technique has yet emerged.

The technique described here allows the sampling of most of the fibres supplying any specific area of the skin. 1 cm of nerve trunk (in our experiments the great auricular nerve of the rabbit) is exposed near to its origin and a pair of platinum stimulating electrodes, 5 mm apart, are hooked under it in a pool of mineral oil. A few mm of the same nerve are exposed 3 cm distal to the stimulating electrodes and hooked up on a single platinum recording electrode. Square wave pulses are applied to the stimulating electrodes and the threshold for activity of all fibres is determined. The recording electrode is then removed and a 'Perspex' ('Lucite') support placed under the nerve. Supra-threshold pulses at about 5/sec are applied to the stimulating electrodes and a glass micropipette filled with 3 M sodium chloride is driven radially into the nerve bundle until a characteristic single-fibre action potential shows on the oscilloscope.

The criteria we used for single-fibre activity were: the sudden onset and cut-off of the action potential as stimulus intensity was raised or lowered respectively, and the constancy of the latency and waveform of the action potential when the stimulus was increased up to ten times the threshold value. The amplitudes varied between 0·2 and 10 mV. Conduction velocities of 105 fibres from six rabbits are shown in the histogram (Fig. 1). The range, 1·5–66 m/sec, shows that even some 'unmyelinated' fibres were being sampled and preliminary histological controls indicate that there was little bias in the selection of fibres within this group. The method gives a highly localized lead and very rarely was more than one unit recorded at once.

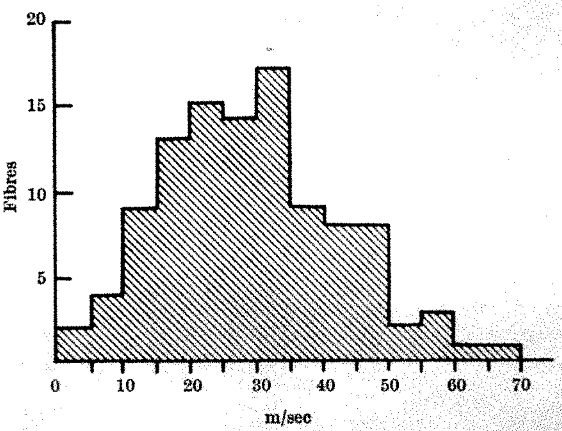

Fig. 1. Histogram of the conduction velocities of 105 single nerve fibres measured at 36°–37° C

Various types of microelectrode, used for single unit recording in the central nervous system, have been tried. Stainless steel[7] or tungsten[8] wire, etched to 0·5μ and dipped in lacquer, buckled too easily against the tough connective tissue of the peripheral nerve bundle. Silver[9], stainless steel or tungsten wire, similarly etched and threaded into glass sleeves drawn down to 1μ internal diameter gave the required structural rigidity, but presented too large a surface area, with the result that during electrical stimulation the compound action potential tended to mask the AP of the single fibre. Glass micropipettes, however, of fairly abrupt taper less than 0·5μ tip, filled with 3 M sodium chloride, of resistance 35–90 Mohms, give consistent results.

When a single fibre has been located by electrical stimulation, the stimulator is switched off and the skin explored distally for the receptive field. With the head of the animal firmly clamped and the micromanipulators rigidly mounted, the electrode tip remains close to the fibre located and we have regularly made recordings for 30 min without deterioration. In some experiments up to 25 per cent of the myelinated fibres have been sampled from bundles containing 50–100 fibres and their receptive fields plotted.

Radial Bands in the Optic Nerve Myelin Sheath

WHILE examining the histochemistry of the optic nerve, we observed beaded transverse band-like areas, which were more dense than the other areas in the myelin sheath in osmium-tetroxide-fixed tissues

(Fig. 1 *A*, arrows). These beads of dark areas in the myelin sheath were fairly constantly observed in cross as well as in longitudinal sections. The bands became very clear when the osmium-tetroxide-treated, paraffin-embedded sections were cleared in xylol, immersed in turpentine or dioxane for 1½ h, and then cleared again in xylol and mounted in dibutylphthalate polysterene xylene mounting medium. With this procedure, banded arrangements of beads were clearly seen (Fig. 1 *B*, arrows), and the lipid material which is in between these beads had been extracted, whereas the beads themselves were left unextracted. This suggests that these dark beaded areas in the myelin sheaths of the optic nerve, which are seen in osmium-tetroxide-treated material, are resistant to fat solvents. It is probable that these banded areas are made up of some kind of proteolipid or polysaccharide material which is resistant to fat solvents.

The bands extend from the axon throughout the myelin sheath; the number is not constant. We have seen the same type of banded appearance in the trigeminal and facial nerves[1], and Tewari and Bourne[2] have recorded it in the sciatic nerve.

While we were preparing our material on the optic and cranial nerves for publication, a paper by Peters appeared on electron microscopic studies of optic nerve of rats, mice and toads in which he describes a radial component in optic nerves fixed in osmium tetroxide, embedded in araldite, and stained with potassium permanganate or lead acetate. In low-power electron micrographs of transverse sections of central sheaths, these dense lines can be observed, arranged radially (Fig. 1 *C*, 1) across the thickness of some of the sheaths at right angles to the lamellæ. These lines tend to occur in groups, and most of the lines extend throughout the thickness of the sheaths.

With higher resolution, Peters[3] has shown that the lines are not continuous, but are composed of a series of thickenings of intraperiod lines (Fig. 1 *C*, 2). A somewhat similar appearance has been observed in longitudinal sections of sheaths.

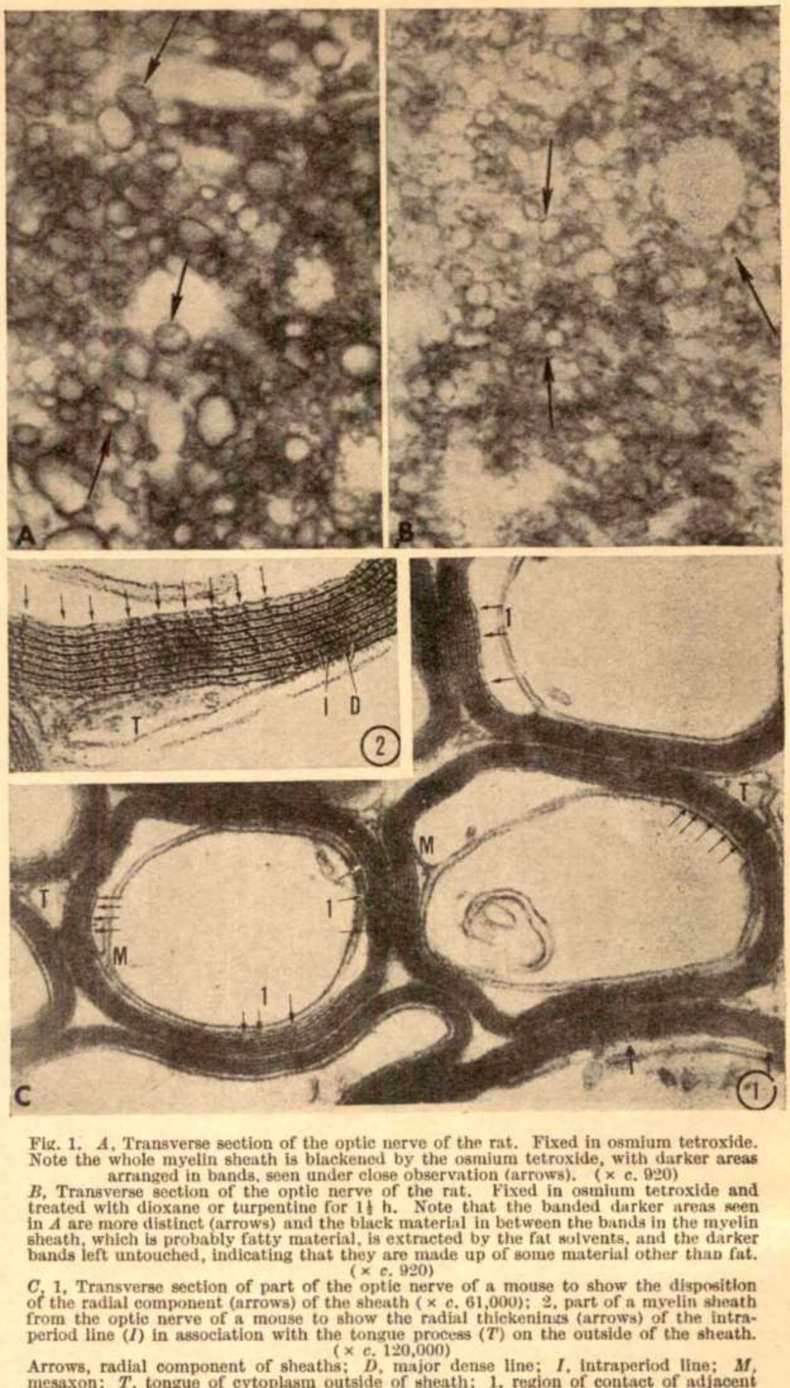

Fig. 1. *A*, Transverse section of the optic nerve of the rat. Fixed in osmium tetroxide. Note the whole myelin sheath is blackened by the osmium tetroxide, with darker areas arranged in bands, seen under close observation (arrows). (× *c*. 920)
B, Transverse section of the optic nerve of the rat. Fixed in osmium tetroxide and treated with dioxane or turpentine for 1½ h. Note that the banded darker areas seen in *A* are more distinct (arrows) and the black material in between the bands in the myelin sheath, which is probably fatty material, is extracted by the fat solvents, and the darker bands left untouched, indicating that they are made up of some material other than fat. (× *c*. 920)
C, 1, Transverse section of part of the optic nerve of a mouse to show the disposition of the radial component (arrows) of the sheath (× *c*. 61,000); 2, part of a myelin sheath from the optic nerve of a mouse to show the radial thickenings (arrows) of the intraperiod line (*I*) in association with the tongue process (*T*) on the outside of the sheath. (× *c*. 120,000)
Arrows, radial component of sheaths; *D*, major dense line; *I*, intraperiod line; *M*, mesaxon; *T*, tongue of cytoplasm outside of sheath; 1, region of contact of adjacent sheaths.
(*C* is taken from Peters, A., *J. Biochem. Biophys. Cytol.*, **11**, 3, 735 (1961) by kind permission of Dr. Peters and the Editors of the *Journal*)

Gray (cited from Peters[3]) has observed similar radial component in sheaths of cerebral cortex fibres also.

Until recently very little evidence has been brought forward that the peripheral nerves also contain such a banding which can be seen under the electron microscope. The only report hitherto available is that of Robertson[4], whose figures show fine radial filaments passing through the peripheral nerve myelin, indicating the presence of such a banding.

The radial banded beads in the myelin sheaths of the optic and cranial nerves, which become very clear in our preparations after turpentine or dioxane extraction, appear to represent a whole group of the radial bands seen under the electron microscope. Due to the low resolution of the light microscope and due to an optic illusion, they appear as broad bands in the myelin sheath.

This work was carried out by the aid of grant *B*-1914 from the National Institute of Neurological Diseases and Blindness, U.S. Public Health Service.

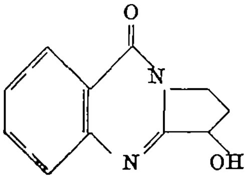
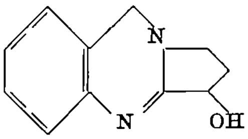
PHARMACOLOGY

Bronchodilating Action of Vasicinone and Related Compounds

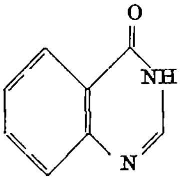
Amin and Mehta have claimed[1] that vasicinone (I), which they obtained by aerial oxidation in sunlight of crude extracts of *Adhatoda vasica* or of pure vasicine (II), the shrub's main alkaloid, has a bronchodilating action. They suggested that this property is attributable to the quinazol-4-one ring system for they found it to be common to the parent substance (III) and various simple derivatives[2]. Vasicine, on the other hand, proved to have a bronchoconstricting action, and the bronchodilator effects variously attributed[3] to preparations containing it they ascribed to contamination by small amounts of vasicinone.



I



II



III

To make some quantitative assessment of these claims we have examined quinazol-4-one (III), *l*-vasicine and *dl*-vasicinone. As we were unable to repeat the photochemical oxidation of vasicine mentioned by the Indian authors we prepared racemic vasicinone in moderate (30 per cent) but reproducible yield by acetylating *l*-vasicine with acetic anhydride, oxidizing the product with chromic oxide in acetic acid and finally removing the protecting acetyl group by alkaline hydrolysis.

In vitro tests on guinea pig tracheal rings showed that vasicinone and quinazol-4-one produced relaxation at 100 μg/ml., thus having about 1/2,000 the activity of adrenaline, whereas vasicine caused slight relaxation at 10 μg/ml. but contraction at higher concentrations.

Against histamine-induced contraction of the isolated tracheal chain vasicinone was about 1/5 as active as 4-quinazolone and about 1/3,800 as active as adrenaline.

In vivo studies on guinea pigs under urethane anæsthesia were made using the Konzett–Rössler[4] technique. Vasicine in doses above 400 μg/kg intravenous produced an increase in resistance of the lungs to inflation, taken as an indication of bronchoconstriction. No evidence of bronchodilation was seen even in the presence of atropine 1 mg/kg (cf. Chopra[3]). This is in agreement with the finding of Southwick and Cremer[5] in the dog and Amin and Mehta[1] in the guinea pig. This bronchoconstrictor action may be related to the reported acetylcholine potentiating properties of vasicine[6].

When given intravenously 4–6 min before the administration of bronchoconstrictor doses of histamine, the alkaloid showed no antagonistic action, but when given 30 sec before, the histamine antagonism was obtained with recovery of the histamine response within 5 min. From dose-response lines it was established that 38 μg of vasicine were required to reduce the response produced by 2 μg of histamine to that elicited originally by 1 μg of histamine. The dose required to produce a similar effect against 5-hydroxytryptamine was 160 μg and the response to acetylcholine could not be blocked with a dose below that which produced bronchoconstriction. The antihistamine effect, although specific, is very weak and of short duration.

With vasicinone and quinazol-4-one the same degree of inhibition of the histamine response could not be achieved as was possible with vasicine. Doses up to 100 μg produced some reduction in response to 2 μg of histamine, but on increasing the dose of either substance a decrease in antagonism was obtained. These doses were well below those required to produce bronchoconstriction.

In summary, therefore, we may say that on isolated tracheal muscle quinazol-4-one and vasicinone are about 1/2,000 as active as adrenaline in producing relaxation and 1/700 and 1/3,800 (respectively) as active against histamine-induced contraction. In the intact guinea pig the compounds showed no bronchodilator activity and were bronchoconstrictor at high doses. Vasicine was the most active compound against histamine-induced bronchospasm; it was fairly specific and had a very short duration of action. Vasicinone and quinazol-4-one showed only slight activity against histamine and antagonism decreased on increasing the dose.

The differences *in vivo* and *in vitro* suggest that we are measuring very different effects and the short duration of action *in vivo* indicates rapid removal or metabolism of these compounds. Their bronchodilator activity is in no way comparable with known bronchodilator drugs.

HÆMATOLOGY

Levels and Uptake of Ascorbic Acid from Plasma by White Cells, Platelets and Leukæmic Cells

It has previously been shown that white blood cells are capable of absorbing ascorbic acid against a concentration gradient from plasma, or from plasma diluted in a solution containing saline, ethylenediamine tetraacetic acid and dextran[1]. This investigation has been continued and extended to include an assessment of uptake by granulocytes, lymphocytes and platelets.

Where estimation of absorption of ascorbic acid by white cells from plasma was carried out for varying periods of time, controls (consisting of separated white cells and plasma) were kept at the same temperature. At the end of the experiment, trichloroacetic acid (which acts as a protein precipitant and stabilizer of ascorbic acid) was added, and the ascorbic acid was estimated by the 2,4-dinitrophenylhydrazine method[1].

Table 1. PLASMA AND CORRESPONDING WHITE BLOOD CELL ASCORBIC ACID LEVELS IN RANDOM BLOOD SPECIMENS

Plasma (μg/ml.)	White blood cells (μg/10^8)	Plasma (μg/ml.)	White blood cells (μg/10^8)
1·1	15·6	8·2	30·7
1·1	25·5	8·9	64·3
2·9	16·7	10·8	32·8
3·2	46·9	12·0	36·8
5·2	33·6	16·5	28·5
7·1	26·7	17 0	45·9

Table 2

	Plasma ascorbic acid (μg/ml.)	White blood cell ascorbic acid (μg/10^8 cells)	White blood cell ascorbic acid after cells have been 4 h in contact with plasma in diluent at 4° C (μg/10^8 cells)
Fasting	5·2	22	33
3 h after 700 mg of ascorbic acid	17·0	27	46
Fasting	7·1	26	30
3 h after 700 mg of ascorbic acid	20·0	27	52

Plasma and white cell ascorbic acid levels in the fasting state and 3 h following an oral dose of 700 mg of ascorbic acid.

Table 1 shows no correspondence between white blood cell and plasma ascorbic acid levels when blood was taken at random times from patients who were not fasting. Because of this poor correlation the levels of plasma and white blood cell ascorbic acid and the uptake by the white cells were determined before and 3 h after an oral dose of 700 mg of ascorbic acid. Two cases giving typical results are shown in Table 2. It can be seen that there is only a small rise in white blood cell levels, coinciding with a much greater rise in plasma levels. However, the uptake of ascorbic acid by the white cells is greater when they are left *in vitro* in contact with the plasma having the higher level. It can thus be appreciated why a high plasma level is not always associated with a high white blood cell ascorbic acid level, and it is conceivable that when body stores of ascorbic acid are depleted, a low plasma fasting level may be obtained in the presence of a high white blood cell ascorbic acid level. When white blood cells from patients with low fasting levels were suspended for four hours in plasma obtained from a normal person 3 h after an oral loading dose of 700 mg of ascorbic acid, rises from 9·7 to 30·7 and 20·9 to 64·3 μg of ascorbic acid per 10^8 white blood cells were obtained.

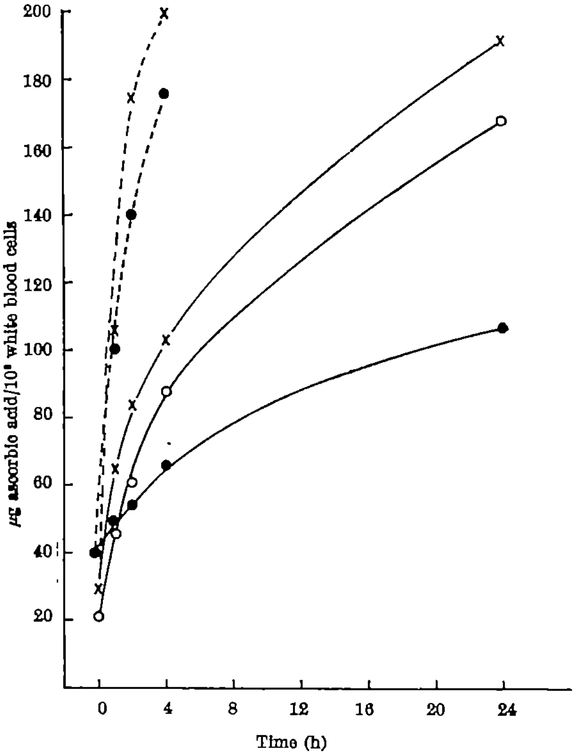

Fig. 1. Uptake of ascorbic acid by normal white blood cells suspended in plasma and diluent with ascorbic acid added at a concentration of 2·5 mg/100 ml. ——, 4° C; – – –, 37° C. The results shown are representative of 10 cases

In the present and all previous estimates of white blood cell ascorbic acid levels and white blood cell uptake, no attempt has been made to separate the platelets, and all assessments of cell content and uptake of ascorbic acid have included any contribution by platelets as a contaminating fraction. To achieve a separation, blood was collected in siliconed apparatus, and platelet rich, leucocyte free plasma obtained by differential centrifugation. The ascorbic acid content of the platelets and their uptake from plasma were determined as previously described for leucocytes. The results of one such experiment are shown in Table 3, in which it can be seen that uptake of ascorbic acid by the platelets is accompanied by a loss of similar amount from the plasma. The results for the ascorbic acid content of platelets shown in Fig. 2*a* are expressed as μg/5 × 10^9 platelets in comparison with values for white blood cells expressed as μg/10^8 white blood cells. Because of the small number of cases examined and the errors involved in platelet counting and fragmentation during preparation, it is difficult to compare the results with those for white cells.

The differential separation of neutrophils, lymphocytes and platelets was next carried out by the albumin gredient method of Spriggs and Alexander[2].

Table 3. UPTAKE OF ASCORBIC ACID BY PLATELETS FROM 1 ML. OF PLASMA AND THE CORRESPONDING DECREASE OF ASCORBIC ACID IN THE PLASMA

μg ascorbic acid in platelets separated immediately	μg ascorbic acid in platelets separated after 4 h	Difference (μg)	μg ascorbic acid in plasma before absorption	μg ascorbic acid in plasma after 4 h in contact with platelets	Difference (μg)
3·1	7·8	4·7	15·2	10·8	4·4

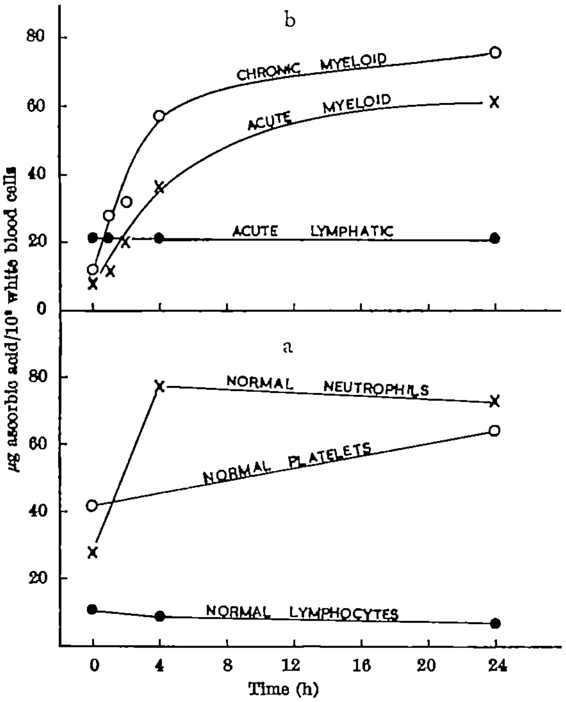

Fig. 2. *a*, Uptake of ascorbic acid as in Fig. 1 by neutrophils, lymphocytes and platelets. The levels for platelets are shown as μg/5 × 10^7 platelets. *b*, Uptake of ascorbic acid as in Fig. 1 by leukæmic cells

The fractions were suspended in diluent plus ascorbic acid at a final concentration of 2·5 mg/100 ml. and the uptake at 4° C after 4 and 24 h determined. The results are shown in Fig. 2*a*. The increases in ascorbic acid content of the neutrophils after exposure to diluent plus ascorbic acid are less than would be anticipated in comparison with the normals of Fig. 1. This may be due to cell damage occurring during the process of separation. The lymphocytes, which appeared morphologically intact after the separation, showed no uptake of ascorbic acid.

The white blood cell ascorbic acid levels and uptake of leukæmic cells at 4° C are shown in Fig. 2*b*. In each case, the amount of blood added to diluent was adjusted so that the ratio of cells to diluent was comparable with that in the normals. The results support the findings of Waldo and Zipf[3], who obtained low levels of plasma ascorbic acid in leukæmia and other conditions involving blood-forming organs. Fig. 2*b* also shows that immature granulocytes take up ascorbic acid, but the data are too few for relative assessment. It is conceivable that this is an apparent result, and that a higher uptake is masked by a greater utilization of ascorbic acid by immature cells. Abnormal cells of the lymphocyte series in common with the normal lymphocytes of Fig. 2*a* showed no uptake of ascorbic acid.

Free Amino-Compounds in Blood Platelets

PLATELETS contain 0·31–0·39 mg nitrogen per 10^9 platelets. Of this, 83–92 per cent is protein nitrogen[1]. Although platelets are the main source of histamine and serotonin (5-hydroxytryptamine) in blood[2], nothing is known of the free amino-acids therein. It was thus of interest to determine the total free amino-acid content of platelets and to identify individual components.

Total α-amino nitrogen: The concentrations in platelets from normal individuals and certain patients, some with platelet anomalies, are given in Table 1.

Table 1. TOTAL FREE AMINO-NITROGEN IN PLATELETS

Condition	No. of cases	Platelet count/mm³ (10³)	Total amino-nitrogen (μg/10^9 platelets)
Thrombocytopenia			
No operation*	2	90–170	9·1–16·0
Post-splenectomy	6	275–620	4·9–8·2
Allergic purpura	4	350–525	5·1–5·7
Thrombocythæmia	1	1,200	10
Polycythæmia	2	276–672	6·4–9·0
Haemochromatosis	2	210–240	5·4–9·0
Normal individuals	5	220–280	5·8–9·2

* Treated with steroids.

Identification of amino-acids: Using two-dimension paper chromatography, four amino-acids, namely, aspartic and glutamic acids, serine and glycine, were identified as well as a peptide with R_F 0·55–0·60 in phenol and 0·10–0·12 in butanol–acetic acid. After acid hydrolysis, alanine, tyrosine and leucine(s) appeared and the spots produced by glycine and serine showed increased density. This distribution would appear to be specific, being different from that in plasma[3] and in normal and leukæmic white blood-cells[4].

The possible identification by paper chromatography of serotonin and histamine in appropriate extracts of platelets was also investigated. Table 2 shows the R_F values of these substances in 3 solvents. To detect these substances, however, aliquots containing at least 10 µg nitrogen were required. Since 10^9 platelets contain less than 0·1 µg histamine and 0·2–0·4 µg serotonin[2] no corresponding spots could be identified in platelet extracts with a total amino-nitrogen of 45 µg.

Table 2. R_F VALUES OF HISTAMINE AND SEROTONIN

Compound	Solvent		
	Phenol	Butanol–acetic acid	77% ethanol
Histamine	1*	0·16	0·7
Serotonin	0·96	0·58	0·8

* Moving with solvent.

Effect of glass contact: All the above investigations were carried out in siliconed glass. Further experiments demonstrated that using untreated glass for washing platelets before extraction resulted in an appreciable loss of amino-acids, the peptide being the only compound detected on a chromatogram.

Serum Protein Synthesis in Fœtus Haptoglobins and Group-Specific Components

Methods of starch-gel and immuno-electrophoresis allow a division of the haptoglobins (Hp), the group-specific components (Gc) and the transferrins into several genetically determined types[1-3].

The existence of haptoglobin, group-specific component and transferrin proteins in cord sera, which differ from the corresponding maternal protein types, seem to show that new-born children in some cases synthesize their own haptoglobin, group-specific component and transferrin proteins[4-6].

We have recently investigated a twin-couple of still-born fœtuses which were of different sexes and also belonged to different ABO-, MN- and Rh-groups. Both twins had well-developed haptoglobin and group-specific component patterns qualitatively and quantitatively indistinguishable from the adult normal patterns, as determined by starch-gel and immuno-electrophoresis. The blood and serum types of the mother and her two children are given in Table 1 and in Table 2 (Nos. 13–15). The differences in haptoglobin and group-specific component-types between the twins and the mother strongly imply that both twins were able to synthesize their own haptoglobin and group-specific component proteins. As regards the Gm types, the twins and the mother lacked the Gm^a antigen and are thus not informative on the development of the Gm^a character.

Table 1. Blood- and Serum-Groups of Mother and Her Two Still-born Fœtuses

	Blood group	Serum group Gm-type	Hp-type	Gc-type
Mother	A MN Rh$_1$rh	*a*–	2–1	2–2
Twin 1	O N Rh$_1$rh	*a*–	2–2	2–1
Twin 2	A M Rh$_1$Rh$_1$	*a*–	1–1	2–1

In addition, determinations of haptoglobin were carried out on three, and determinations of group-specific components on six, further fœtal sera ranging in age from 17 to 30 weeks. In two sera (Nos. 4 and 8) haptoglobins were detected with the conventional starch-gel electrophoretic technique with borate buffer and benzidine-staining, and in one of these sera (No. 4) the child belonged to a haptoglobin type different from that of the mother (Table 2). In no case could the group-specific component precipitate be demonstrated (Table 2). Two of the fœtal sera (Nos. 4 and 10) were used in absorption of an anti-immune serum containing antibodies both against the haptoglobins and the group-specific components. Both sera had the capacity of absorbing the antibodies against the group-specific component as revealed by immuno-electrophoretic analysis of the absorbed immune serum against normal sera containing the haptoglobin and group-specific component protein. Serum No. 4 also absorbed the antibodies against the haptoglobins, whereas serum No. 10 did not. The absorption was carried out in the gel according to a technique described previously[7].

Table 2. Clinical and Laboratory Data on Seven Mother–Fœtal Samples

No.		Length (cm)	Age (weeks)	Hp	Gc
1	Mother	—	—	n.d.	2–1
2	Fœtus	18	17	n,d.	absent
3	Mother	—	—	1–1	2–1
4	Fœtus	29	21	2–1	absent
5	Mother	—	—	n.d.	1–1
6	Fœtus	22	20	n.d.	absent
7	Mother	—	—	1–1	1–1
8	Fœtus	17	17	1–1	absent
9	Mother	—	—	2–1	1–1
10	Fœtus	38	30	absent	absent
11	Mother	—	—	n.d.	2–1
12	Fœtus	20	17	n.d.	absent
13	Mother	—	—	2–1	2–2
14	Fœtus 1	30	25	2–2	2–1
15	Fœtus 2	30	25	1–1	2–1

Investigation of cord blood from 71 new-born children in all instances gave well-developed group-specific component patterns; where in 29 cases the group-specific component pattern of the child belonged to another type than that of the corresponding mother (Table 3). As regards the haptoglobins, only 10 per cent of 120 investigated cord sera could be haptoglobin-typed[8]. In a recent work by Bergstrand *et al.*[9], no haptoglobin could be demonstrated in six sera from fœtuses between 16 and 26 cm, nor in 29 cord blood sera.

Table 3. Gc-Types of 71 Mother-Cord Samples (Data from Ref. 5 are included)

Gc type	Mother Obs.	Exp.		Child Gc 1–1	Gc 2–1	Gc 2–2
1–1	42	39·5	obs.	33	9	0
			exp.	31·4	10·7	0
2–1	27	26·9	obs.	12	9	6
			exp.	10·1	13·5	3·5
2–2	2	4·6	obs.	0	2	0
			exp.	0	1·5	0·5

Expected frequencies calculated from Gc-frequencies of 2,259 unrelated Swedes. $Gc^1 = 0·7459$, $Gc^2 = 0·2541$ (ref. 10).

In conclusion, it seems as if the synthesis of haptoglobin and group-specific component proteins in the fœtus is subjected to great individual variations, which might indicate differences in 'biochemical maturity'. Further work is in progress of using the haptoglobin and group-specific component protein polymorphisms as a 'physiological tagging' in the evaluation of protein synthesis in the fœtus as well as in the evaluation of turnover of passively transferred serum proteins in new-born children and adults.

PATHOLOGY

Induction of Fibrosarcomas in Mice given a Minute Quantity of 3-Methylcholanthrene or Dibenz(*a,h*)anthracene as New-borns

The susceptibility of new-born mice to chemical carcinogenesis has been reported from several laboratories within the past two years[1-4]. New-born mice (Swiss, *C3H/P*, *C57BL*) given a single low dose of either 3-methylcholanthrene (3-MC) or dibenz(*a,h*)-anthracene (DBA) developed a higher incidence of pulmonary tumours and more tumour nodules per lung in a shorter time than did adult mice[5].

The experiment reported here was designed to determine the minimum carcinogenic dose of 3-MC and

Olive oil controls 0·0	85	0	0	0	0	0	0	—

* In 0·05 ml. olive oil. † Mice living to 13 weeks of age or older.

DBA in new-born non-inbred albino mice (NIH General Purpose mice). Eight logarithmically spaced dose-levels of each carcinogen were used. For 3-MC, the doses varied from 11·1 μg to 0·0051 μg; for DBA the range was 6·7 μg–0·0031 μg. The carcinogens were dissolved in olive oil in such concentrations that the desired dose was contained in 0·05 ml. of vehicle. Control mice received 0·05 ml. of olive oil. 130 litters were randomly distributed among treatment and control groups, 6–8 litters in each of the 16 treatment groups and 13 in the control group. Each mouse was given a single subcutaneous injection of carcinogen (or vehicle) within 12 h after birth. The animals were weaned at 4 weeks of age, separated by sex and housed in groups of 5–8 animals per cage. The mice were observed for more than a year for the development of tumours; animals were killed only if they developed tumours or became moribund. Because of persistent fighting among the males, all surviving male mice were killed and autopsied at 55 weeks of age. Surviving females, however, are still under observation. As of age 55 weeks there was no apparent difference in the incidence of subcutaneous tumours or in latent period between males and females, and the results for both sexes have been combined in Table 1. The subcutaneous tumours measured 0·3–3·4 cm in diameter, and all were diagnosed histologically as fibrosarcomas. Only subcutaneous fibrosarcomas appearing within 55 weeks after administration of carcinogen are reported here. The incidence of other tumours and any later subcutaneous fibrosarcomas which develop will be reported when the experiment is terminated and the final results are tabulated.

The results with 3-MC show no change in the incidence of fibrosarcoma at doses between 11·1 μg and 1·2 μg. There is a sharp drop in the incidence at the 0·41-μg level, and at the 4 lowest doses of 3-MC (0·14–0·0051 μg) no subcutaneous tumours were induced in 173 mice within 55 weeks. With DBA, however, there is a more gradual decrease in tumour incidence with decreasing dose. Tumours appeared within the 55-week period in 2 of 161 mice administered the 3 lowest doses (0·028–0·0031 μg). Both the time of appearance of the earliest tumours (13–16 weeks) and the median latent period to tumour appearance were about the same for the two carcinogens used. Although the latent period of tumour formation was not closely related to the dose, it tended to be somewhat longer at the lower dose-levels.

The doses of carcinogen at which fibrosarcomas were induced in this experiment (0·41 μg of 3-MC; 0·0031–0·083 μg DBA) are, to the best of our knowledge, the lowest amount of chemical carcinogen ever reported to induce tumours. It may be that use of the new-born mouse provides a more sensitive system than the adult for assaying the carcinogenic activity of polycyclic hydrocarbons, and perhaps also of other chemical agents.

Effect of Starvation and of Adrenalectomy on Compensatory Hyperplasia of the Kidney

COMPENSATORY hyperplasia of the kidney has frequently been used as a model for the investigation of regeneration. However, the effect of the intake of food on the mitotic response has not to my knowledge been commented on, and the effect of adrenalectomy is disputed[1,2]. Some observations made during a study of the control of compensatory hyperplasia seem interesting enough to justify a short report.

The animals used were male albino rats weighing 118–180 g from a colony of Wistar origin. Groups of animals were bilaterally adrenalectomized and maintained on a normal diet (M.R.C. diet 14*B*) with 0·9 per cent sodium chloride solution as their water supply. In addition, one kidney was removed from some animals at the time of adrenalectomy: others had a unilateral nephrectomy without adrenalectomy, and others a sham operation: the last three groups were either starved or allowed free access to food post-operatively, and groups were killed at 8-h intervals

Table 1

	8 h		16 h		24 h		32 h		40 h		48 h

Total mitotic counts: the number of animals in each group is given in parentheses and the mean count is given with the standard deviation of the mean.

A, Unoperated normally fed animals killed at that time of day; *B*, unilaterally nephrectomized animals allowed free access to food; *C*, bilaterally adrenalectomized animals allowed free access to food; *D*, bilaterally adrenalectomized unilaterally nephrectomized animals allowed free access to food; *E*, bilaterally adrenalectomized unilaterally nephrectomized animals starved post-operatively; *F*, unilaterally nephrectomized animals starved post-operatively; *G*, sham-operated animals starved post-operatively.

over the 48 h after operation. All operations were performed at 2–4 p.m. The remaining kidneys were removed and fixed immediately after death, and 5μ paraffin sections prepared and stained with hæmatoxylin and eosin. Mitoses were counted over a standard area (1·1 mm^2) in each of the four zones of the kidney as in previous work[3]. The total number of cells of all types examined per kidney was approximately 32,000, of which some 17,000 belonged to the renal tubules: as in previous investigations, mitoses were found to be almost confined to the tubules. Only one kidney of the animals which had been adrenalectomized without unilateral nephrectomy was used to avoid the risk of under-estimating the variance due to agreement between the counts of the two kidneys. The kidneys of animals showing pyelonephritis or hydronephrosis were discarded. The total number of mitoses seen in all four zones was calculated and the results are given in Table 1.

Series *A* and *B* are based partially on previously published material[3] and show: *A*, the normal diurnal rhythm; *B*, the early mitotic response in the remaining kidney of fed animals, with a sharp peak at 40 h. It can be seen from series *F* that in animals which have been starved post-operatively this peak is greatly diminished, and compared with the mitotic counts in unoperated controls is almost abolished: however, the sham-operated controls (series *G*) starved after operation have a very much lower mitotic rate than the normally fed animals of series *A* ($P < 0{\cdot}02$), and compared with series *G* the unilaterally nephrectomized starved animals show a very considerable mitotic increase ($P < 0{\cdot}01$). Adrenalectomy alone (series *C*) considerably distorts the normal mitotic rhythm; unilaterally nephrectomized adrenalectomized rats (series *D*) show a definite increase in the mitotic rates over the adrenalectomized controls of series *C* at 32–48 h ($P < 0{\cdot}01$ in each case). Unilaterally nephrectomized rats from which both adrenals have been removed and which had been starved post-operatively had counts not significantly above those of starved uninephrectomized animals with intact adrenals (series *F*), except at 24 h when the chance probability of the difference is 0·05–0·02: the significance of this single reading in the series is dubious. All probabilities were calculated by the *t* test: it has been shown[3] that the distribution of mitotic rates between animals is often somewhat skew, though this was not obvious in the small groups studied. However, as the *t* test is not very sensitive to small deviations from normality, the calculated probabilities are probably valid.

The conclusions would seem to be: (1) that starvation depresses the normal mitotic rate; (2) that the mitotic response of compensatory hyperplasia is considerably diminished by starvation compared with that in fed animals, but only slightly, if at all, relative to starved controls, and that this diminution is not affected by adrenalectomy; (3) that adrenalectomy alters the normal diurnal rhythm and the pattern of the mitotic response of compensatory hyperplasia but does not abolish this.

Bullough and Laurence[4] have found that starvation produces a depression in the mitotic rate of mouse epidermis, and that this effect is abolished by adrenalectomy; however, adrenalectomy does not seem to affect the reduced renal hyperplasia of starved rats. Goss and Rankin[2] stated that adrenalectomy inhibited compensatory renal hyperplasia on the basis of mitotic counts 48 h after operation: however, their controls were not adrenalectomized, and it would seem that hyperplasia will in fact occur, though the peak is less sharp than normally. The effect of starvation is obviously important in planning experiments on compensatory hyperplasia and may produce misleading results if ignored[5].

Catechol-O-Methyltransferase Activity in Neuroblastoma Tumour

Von Studnitz[1], Greenberg and Gardner[2], and Voorhess and Gardner[3] have reported marked elevations in the urinary excretion of 3-*O*-methylated metabolites in the urine of patients with neural tumours. It is possible that these urinary products arise mainly from *O*-methylation of their precursors in the liver. However, the fact that some of these patients have a normal blood pressure in the presence of a large endogenous production of norepinephrine suggested to us that metabolism of the norepinephrine may occur within the tumour.

We have used the assay method described by Axelrod *et al.*[4] with minor modifications to examine the tumour for catechol-*O*-methyltransferase activity. This method is very sensitive because of the use of DL-epinephrine-7-^{3}H.

An ovoid tumour (6 × 5 × 4 cm) was excised from the region of the right suprarenal gland of a 13-month old, white, male patient. The tumour was chilled on ice and a 100·3-mg portion was homogenized in 0·6 ml of ice-cold 1·15 per cent potassium chloride solution. The homogenate was centrifuged at 14,500*g* for 20 min. The supernatant solution was examined for catechol-*O*-methyltransferase activity at the same time as a non-particulate fraction of tumour obtained at autopsy from two other patients with neuroblastoma and of rat liver prepared in the same manner.

Three tubes were prepared for each sample; 10 μM of potassium phosphate buffer (0·5 M, *p*H 7·6), 0·5 μM of magnesium chloride (1 M), and 0·6 mμM (2·8 μc.)

DL-epinephrine-7-^{3}H-hydrochloric acid, were added to all the test-tubes. To the first and third tubes, 10 mμM of *S*-adenosylmethionine was also added. The co-factor, *S*-adenosylmethionine, was omitted from the second tube of each set. 50 μl. of the supernatant fraction was added to the first and second tubes of each set; but before it was added to the third tube, the supernatant fraction was heated for 3 min in a 100° water-bath. Therefore, the first tube of each set contained the complete reaction mixture; in the second tube the co-factor was omitted, and in the third tube the enzyme was denatured. The total volume of the reaction mixtures was 100 μl. The reaction mixtures were incubated in 10 × 98 mm test-tubes in a water-bath at 37° for 90 min. After incubation, 10 μl. from each tube were transferred to 0·5 ml. of *p*H 10 borate buffer (0·13 M) and the mixture was extracted with 5 ml. of toluene/isoamyl alcohol (3 : 2). After centrifuging, duplicate 1-ml. portions of the upper phase were added to a fluor solution consisting of 10 ml. of toluene containing 0·4 per cent 2,5-diphenyloxazole and 0·01 per cent 1,4-*bis*-2′(5′-phenyl-oxazolyl)-benzene and 4 ml. of ethanol. The solutions were assayed for radioactivity in a liquid scintillation spectrometer (Tri-Carb scintillation spectrometer, Packard Instrument Co., La Grange, Illinois).

Table 1. CATECHOL-*O*-METHYLTRANSFERASE ACTIVITY IN NEUROBLASTOMA

	C.p.m.* in toluene/isoamyl alcohol extract		
	With *S*-AMe	Without *S*-AMe	Boiled extract
P. H. W.†	1,435	655	955
J. K. S.†	8,015	880	885
D. H. W.‡	1,685	950	1,105
Rat liver	23,385	970	1,135

* Corrected for background See text for details of the reaction mixtures and extraction procedure.

† Tumour tissue was obtained at autopsy from these patients.

‡ In the case of this patient, tumour tissue was obtained at laparotomy.

The results of the assay are presented in Table 1; it can be seen that significantly more radioactivity was extracted by the toluene–isoamyl alcohol from the complete reaction mixtures. If the co-factor was omitted, or if the enzyme was denatured, less radioactivity was extracted. Under conditions of the assay, only about 2 per cent of the radioactivity of the ^{3}H-epinephrine is extracted into the toluene–isoamyl alcohol, but 50 per cent of the ^{3}H-metanephrine is extracted. Portions of the toluene–isoamyl alcohol extracts were evaporated to dryness under a stream of nitrogen, and the residues were transferred to a sheet of Whatman No. 1 filter paper with ethanol. The chromatogram was developed in isopropanol/7 N ammonia solution (4 : 1), dried, and scanned for radioactivity. One large peak of radioactive material was present, and this corresponded to added metanephrine. In addition, 10-μl. portions of each of the incubation mixtures were chromatographed in the *n*-butanol/glacial acetic acid/water system (4 : 1 : 1). Two radioactive areas were detected on the chromatograms of the complete reaction mixture from each tumour; these areas corresponded to epinephrine and metanephrine. The chromatograms of the incubation mixtures from which *S*-adenosylmethionine was omitted and the mixtures to which boiled enzyme was added showed only one radioactive area which corresponded to epinephrine.

This evidence indicates that catechol-*O*-methyltransferase is present in extracts of the neuroblastoma tumours; under the conditions used ^{3}H-epinephrine was converted to ^{3}H-metanephrine.

The only other report of an examination of catechol-*O*-methyl-transferase activity in tumour of neural crest origin, of which we are aware, is that of Greenberg and Gardner[2]. These authors found no catechol-*O*-methyltransferase activity in tumour tissue from a patient with ganglioneuroma. In the work described here, the presence of this enzymatic activity in extracts of neuroblastoma tumours provides evidence that norepinephrine may be at least partially metabolized within the tumour, and in this way elevated levels of norepinephrine metabolites may be formed in the absence of a corresponding elevation in blood norepinephrine.

The difference between the findings of Greenberg and Gardner and ours may represent a difference in the tumours or may result from the much greater sensitivity of the assay method using tritium-labelled epinephrine.

In addition to the findings reported here, a similar result has been obtained using ^{3}H-norepinephrine in our laboratory.

RADIOBIOLOGY

Influence of Ionizing Radiation on Glutaminase Activity in Mouse Brain and Liver

IN 1940, Dale[1] demonstrated that carboxypeptidase activity is inhibited if submitted to small doses of X-rays. Bekkum[2], Potter[3] and Nadson[4] showed that under ionizing radiations primary changes occur in the mitochondria. We have investigated the variations of the *in vivo* behaviour of glutaminase activity in liver and brain of mice submitted to an overall 58-min irradiation with 500 r.

Table 1 shows that after 2 h following irradiation there is still a significant inhibition of glutaminase activity which increases progressively 24 and 48 h after irradiation. Table 2 shows that 2 h after irradiation brain glutaminase does not exhibit any significant change in its activity. After 24 h, and especially after 48 h following irradiation, the activity of this enzyme is inhibited significantly.

Table 1. CHANGES OCCURRING IN GLUTAMINASE ACTIVITY AFTER A TOTAL IRRADIATION WITH 500 R., FOR 58 MIN IN MOUSE LIVER (TOTAL HOMOGENATE)

Activity (refs. 6 and 7) determined in phosphate buffer solution at *p*H 7·4 in the presence of pyruvate

	M mol. NH_3/g liver/h
Normal	0·401
2 h after irradiation	0·276
24 h after irradiation	0·183
48 h after irradiation	0·120

Table 2. CHANGES IN GLUTAMINASE ACTIVITY IN MOUSE BRAIN IRRADIATED *in vivo* WITH 500 R. FOR 58 MIN

Determination performed in phosphate buffer solution at *p*H 8·5 (refs. 7 and 8)

	M mol. NH_3/g brain/h
Normal	1 620
2 h after irradiation	1·564
24 h after irradiation	0·892
48 h after irradiation	0·440

The decrease of the activity of these enzymes situated in the mitochondria could be explained as a consequence of changes in the synthesis of new proteins, and therefore also of enzymal proteins, effects known to be induced by ionizing radiations[4]. Furthermore, both enzymes having active —SH groupings, they may be inhibited by the direct action of X-rays on these groupings as described by Barron[5].

Inhibition of these two enzymes once more supports the fact that ionizing radiations act in the first place on the —SH groupings, oxidizing them, and that they cause primary changes in the mitochondrial structure.

BIOLOGY

Plankton from the East African Area of the Indian Ocean

AN earlier communication[1] has described how a series of plankton samples was taken from the coastal strips of Kenya and Tanganyika, extending outwards for some 50 miles. An analysis of some of the dry-weight data shows the following results.

For Figs. 1*a* and *b* all night samples, shallow water samples (that is, where the total depth was less than 200 fathoms), samples taken within 1 h after sunrise and within 1 h before sunset have been ignored. The remaining samples represent a scattering throughout an area of many thousand square miles.

In association with all these plankton samples Secchi disk readings were taken, using a 50-cm disk, to give a measure of the water transparency.

In Figs. 1*a* and *b* the Secchi disk readings, that is, the water transparency, has been plotted against the dry weight of plankton per m³, this latter being on a logarithmic scale. The regression coefficient has been calculated for each graph and the calculated regression lines indicated. The independent equations are:

$$\text{Fig. 1}a \quad \log y_1 = 1{\cdot}6433 - 0{\cdot}01717x_1$$
$$\text{Fig. 1}b \quad \log y_2 = 1{\cdot}9441 - 0{\cdot}02585x_2$$

In both the regression is significant, $P = < 0{\cdot}001$; the difference between the regression lines is not significant.

Thus the data are consistent with equal rate of fall-off in the plankton dry weight/m³ in the topmost 200 m with increase in transparency.

It might be argued that the relationship between the plankton and the water transparency is direct, the transparency depending on the plankton concentration. There is always a certain amount of suspended inorganic matter in the sea, plus varying concentrations of the microplankton; these might be the direct cause of variations in transparency. It is considered unlikely that the type and quantity of plankton taken in a 74 m.p.i. net, with apertures of 0·205 mm, will influence the transparency to a significant degree.

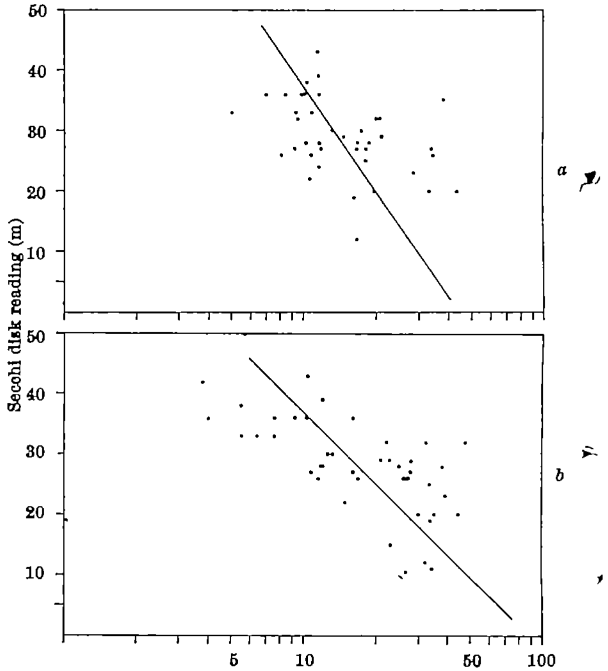

Fig. 1. Diagrams showing the relation of water transparency and plankton dry weight per m³ (on logarithmic scale) from vertical samples taken from 200 m to the surface (*a*) and 50 m to the surface (*b*); the calculated regressions are indicated

A further argument is that as the transparency increases so there is an increased rate of loss of plankton due to net avoidance. There was no evidence to support this.

My conclusions from the data available, applying therefore to the area within the limits of the survey, are as follows.

A small part of the plankton is a normal inhabitant of the topmost layers of the sea; therefore, theoretically, there would always be plankton at the surface even with water of infinite transparency.

The bulk of the plankton reacts according to the degree to which the transparency of the water permits penetration of light; this reaction modifies vertical movements due to negative geotropism, inherent vertical migration patterns, etc. Thus, throughout the area of the survey where the total depth exceeds 200 fathoms, there is, during daylight, no significant variation in the plankton dry weight per unit volume in the topmost 200 m. (The fact that all the points of the graphs do not lie on, or much closer to, the regression lines is no doubt due to the discrepancies inherent with net sampling.) Variations of this plankton indicated previously[1] are not indicative of richer or poorer areas, but of the relative water transparency at the time of sampling.

Clearly this does not preclude the possibility that an assessment of the plankton of the complete water column, extending to beyond 200 m, would show wide variations in relative richness; but it does indicate that plankton estimations based on daylight samples from the topmost 200 m only can be misleading unless the samples are considered in relation to the water transparency.

The variations shown in the shallow water coastal areas do not necessarily conform to the deeper water plankton pattern and are true variations of plankton abundance indicating relatively rich or poor areas.

In Fig. 2 all shallow-water samples have been ignored; the remainder include samples taken at various times throughout the 24-h period. Time and Secchi disk readings are shown as 3-hourly means.

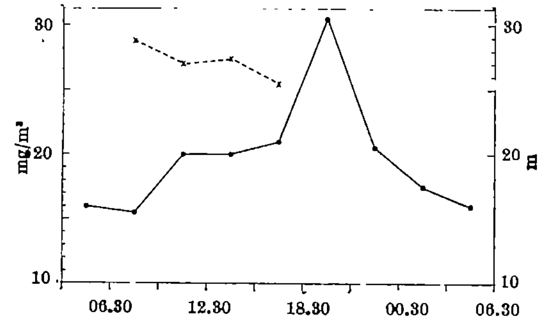

Fig. 2. Diagram showing the variation of the plankton dry weight (mg/m³), taken in vertical samples from both 200 m and 50 m to the surface, throughout 24 h; the former is shown as consecutive 3-hourly means of the latter. Secchi disk readings (m) are also indicated as four consecutive 3-hourly means of the 12-h daylight period

A vertical migration pattern is shown with the single peak occurring between 18.30 and 21.30 h (the annual range of sunset times here is between 18.15 and 18.45 h). Some indication is also given here of the relationship between water transparency and the plankton. As is to be expected the theoretical cross-over point values, about 23 mg/m³–23 m, are very close to the regression line in Fig. 1*b*, less so in Fig. 1*a*.

Effect of Additions of Volatile Fatty Acids on the Viability and Fertility of Diluted Bovine Semen

Although the lower fatty acids will prolong the respiratory activity of washed mammalian spermatozoa for a considerable time[1], we can find no reference to the effects of added fatty acids on the viability and fertility of diluted semen.

Trials have been conducted in this laboratory to compare the viability of semen in diluents with, and without, added volatile fatty acids. The control diluent was 14*G*, which has been shown to give significantly higher conception-rates than 2·9 per cent sodium citrate[2]. (Composition of 14*G* was: 2·0 per cent sodium citrate; 0·3 per cent glucose; 1·25 per cent glycerol; 1·0 per cent glycine; 1,250 units of penicillin and 1,250 μg of streptomycin per ml. The diluent, when finally prepared, consists of 80 per cent buffer and 20 per cent egg yolk.) This diluent was supplemented with acetic, propionic, butyric, valeric, caproic and octoic acids, both separately and in combination with each other. The addition of these fatty acids improved viability at both 5° C and 37° C. The greatest increase in viability was obtained, however, with caproic acid at a final concentration of 0·025 per cent v/v in the diluent.

Consequent on good results in the laboratory, a field trial was conducted in the 1961 spring mating season. The experimental diluent selected for the trial was 14*G* supplemented with 0·025 per cent caproic acid.

This trial was conducted for twelve weeks by the Hamilton A.B. Centre and for six weeks by the Palmerston North Centre. On one day of each of the weeks the trial was operated all semen issued for use in the field was diluted with the experimental diluent. During the period of the trial all bulls were routinely collected every third day. Thus after three weeks semen from all bulls was diluted once with the experimental diluent. All semen used in the trial was used on the day of, or the day after, collection. Semen was diluted to contain 12½ or 18¾ million sperm per ml. depending on the fertility of the bull. While semen from all bulls was used on the same day of collection, only semen from those bulls exhibiting good storage characteristics was used on the day after collection[3].

Conception-rates were measured as the percentage of cows reported as in calf to first inseminations 49 days after service.

The difference of 0·4 percentage units in favour of the control diluent, 14*G*, with semen used on the day of collection, was not significant ($\chi^2 = 3{\cdot}3$ $P > 0{\cdot}05$). With semen used on the day after collection, however, there was a highly significant difference of 2·6 percentage units in favour of the experimental diluent ($\chi^2 = 39{\cdot}9$ $P < 0{\cdot}001$).

Table 1. Conception-Rates of Control and Caproic Acid Supplemented Diluents Percentage of Cows reported in Calf 49 Days after First Service

	Diluent			
	14*G*		14*G* + 0·025% caproic acid	
Age of semen (h)	No. of inseminations	% successful	No. of inseminations	% successful
6–18	224,275	64·1	41,997	63·7
24–36	95,587	64·3	16,831	66·9

The function of volatile fatty acids in prolonging viability and improving fertility in stored semen is not known. It is possible that it is involved as an energy-providing metabolite under the aerobic conditions existing in stored semen. As its utilization is oxygen dependent a comparison was made for viability between samples stored normally and samples stored under 'anaerobic' conditions.

Split ejaculates from 12 bulls were diluted in 14 *G*, 14 *G* saturated with nitrogen (14 *GN*), 14 *G* plus caproic acid (14 *GC*) and 14 g plus caproic acid saturated with nitrogen (14 *GCN*). Comparisons between treatments were made by estimating the viability of samples incubated at 37° C after one to seven days storage at 5° C.

Viability at 37° C for the various treatments was 14 *G*, 24·9 h, 14 *GC* 33·0 h, 14 *GN* 38·7 h, and 14 *GCN* 47·2 h. Each estimate of viability is the mean for 96 samples. The increase in viability obtained by the addition of caproic acid was as great in the 'anaerobic' (8·5 h $P < 0{\cdot}01$) as in aerobic samples (8·1 h $P < 0{\cdot}01$). While some aeration of samples may have occurred in opening the test-tubes during the incubation period, the difference in viability between the aerobic and 'anaerobic' samples is so great (14·1 h $P < 0{\cdot}01$) as to indicate a very real difference in the oxygen status of the two treatments.

While the possibility that caproic acid is utilized as an energy-providing substrate in aerobic samples cannot be excluded, it is apparent from the viability of 'anaerobic' samples that depletion of the energy-providing substrate is not the reason for cessation of motility in these samples, and that the observed increase in viability is probably due to some other function.

In vitro and *in vivo* Survival of Morphologically Atypical Embryos in Rabbits

IN a series of investigations of the storage of rabbit embryos, different types of morphologically atypical embryos were encountered[1,2]. These abnormalities were: presence of excessive red blood cells or air bubbles in mucin coat, persistence of corona radiata cells until 48 h, ruptured zona pellucida, embryos with angularly shaped blastomeres, irregular mucin coat and abundance of hypha-like projections, flattened and lentil-shaped morulæ.

The structural abnormalities of the embryos may be a result of cytological, physiological, genetical, environmental or pathological disturbances. Some of the observed abnormalities are likely to be a result of several causes such as incomplete maturation of ova, faulty fertilization or ageing of gametes. Although not shown by actual investigations, it seems highly probable that aberrations occur in oögenesis similar to those found by Knüdsen[3] in spermatogenesis. There is evidence that the frequency of morphological abnormalities of the embryo is influenced by hereditary factors[4] and the season of the year[5].

The purpose of this experiment was to test the suitability of morphologically atypical embryos (2 days *post coitum*) for storage and subsequent transfer.

Donor (pubertal) and recipient (adult) does of the New Zealand large breed were used. During the main investigation, which is not described here, some 150 donors were superovulated using pregnant mare serum (P.M.S.) (commercial preparation 'Equinex' from Ayerst Laboratories) and human chorionic gonadotrophin (H.C.G.) (from Upjohn). Only 15 donors had typical and atypical embryos in the same animal; these were used in the present study. A total of 96 morphologically atypical and 83 morphologically typical (control) embryos were obtained from the superovulated donors which were bred to fertile bucks and autopsied approximately 40 h *post coitum*. The Fallopian tubes were removed and the embryos flushed into watch glasses and examined with a stereomicroscope (× 60). The atypical embryos were placed in storage tubes in a serum/saline, 1 : 1 media and stored for two days at 10° C. Morphologically typical embryos from the same donor were stored in a second tube of the same media to serve as control.

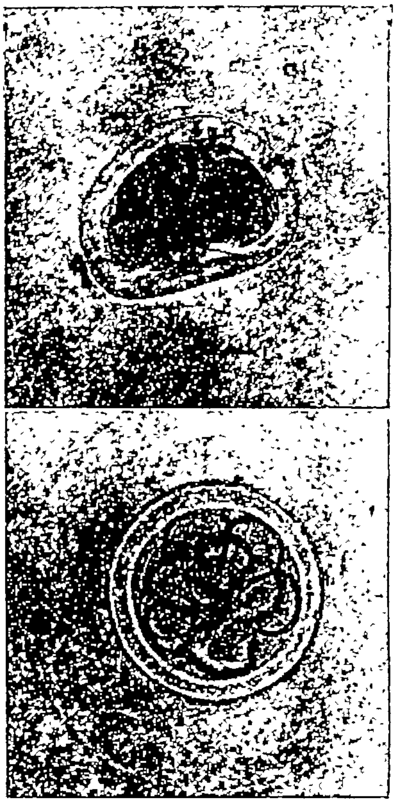

Fig. 1. Atypical (top) and typical (bottom) rabbit embryos recovered from superovulated donors 40 h *post coitum* (× 185). Note the flattened zona pellucida in the atypical embryo and the even size and distribution of blastomeres in the typical embryo

Eighteen recipients were ovulated with an intravenous injection of 15 I.U. of H.C.G. (Upjohn) two days after the donors were bred. Two days post-injection, the embryos were transferred to the Fallopian tube through the fimbriæ via a flank laparotomy. Approximately six embryos were transferred to each Fallopian tube; one side morphologically atypical embryos and the other side control embryos from the same donor. The recipients were laparotomized at 8 days *post coitum* and implantation sites were counted. The pregnant recipients were autopsied 15 days *post coitum* and survival of embryos determined by their heart beat.

Four morphologically atypical groups of embryos were found: embryos with cellular elements between the zona pellucida and the mucin coat (perhaps as a result of delayed denudation of the corona radiata); oval-shaped zona pellucida; flattened zona pellucida; and embryos with indistinct blastomeres (Fig. 1). These four types survived during storage for 48 h at 10° C. The percentage of implantation at 8 days *post coitum* of atypical embryos were statistically similar to that of morphologically typical embryos. However, the percentage of fœtal survival at 15 days

Table 1. IMPLANTATION AND FŒTAL SURVIVAL OF MORPHOLOGICALLY ATYPICAL EMBRYOS AFTER STORAGE FOR 48 H AT 10° C.

* Two recipients dripped off before slaughter. † All embryos had distinct blastomeres after storage. ‡ At 8 days *post coitum*. § At 15 days *post coitum*.

post coitum was lower in three types of atypical embryos than in control. This phenomenon may be due to a 'carry-over effect' in the atypical embryos. It is emphasized that embryos should be carefully selected for subsequent transfer especially in quantitative studies on implantation and embryonic survival. The embryos which showed indistinct blastomeres prior to storage had distinct blastomeres after storage. It is possible that the embryos with the indistinct blastomere were in an incomplete stage of cleavage when taken from the donor. It is also possible that such incomplete cleavage, once started, is completed even when stored at 10° C.

Kvasnitskii[6] had reported that lentil-shaped ova do not normally develop although ovoid-shaped ova develop normally. Hertig *et al.*[7] described different types of morphological abnormalities in human embryos: absence of chorionic cavity, shallow implantation, maloriented germ disk, and different degrees of trophoblastic hypoplasia. Such abnormalities might be subject to subsequent degeneration. It has been suggested that a lack of adequate direct or indirect stimulation by a defective trophoblast may cause the failure of the corpora lutea to undergo secondary hyperplasia, as in normal pregnancy[7]. Further physiological, biochemical, genetic and immuno-embryological studies are needed to understand the relationships between implantation and fœtal survival in a wide spectrum of mammalian species.

Resolution of Endopolygalacturonase and a Macerating Factor in a Fungal Culture Filtrate

THE brown rot fungi, *Sclerotinia fructigena* Aderh. and Ruhl., and *S. laxa* Aderh. and Ruhl., are known to penetrate infected fruits by dissolution of the middle lamella[1], and the macerating effect of culture filtrates of these fungi on disks of plant tissue has been ascribed to pectolytic enzymes[2]. The separate identity of 'protopectinases' (using the nomenclature of Demain and Phaff[3]) has been questioned in recent reviews[3,4]; but the presence of distinct fungal macerating enzymes, without characterized substrates, has been reported in a commercial pectic enzyme[5] and in culture filtrates of two plant-pathogenic fungi[5,6].

In the course of studies on the pectolytic enzymes of *S. fructigena*, dextran gel filtration on 'Sephadex *G*.75'[7] has proved useful for the partial purification of an extracellular endopolygalacturonase. We have examined the macerating activity of the fractions (10 ml.) using Brown's method[8], based on the loss of coherence of 4 disks of potato (1 cm diameter, 0·35 mm thick), immersed in the test solution (2 ml.). Fig. 1 shows the results obtained, together with those of an assay of endopolygalacturonase by the agar plate method[9].

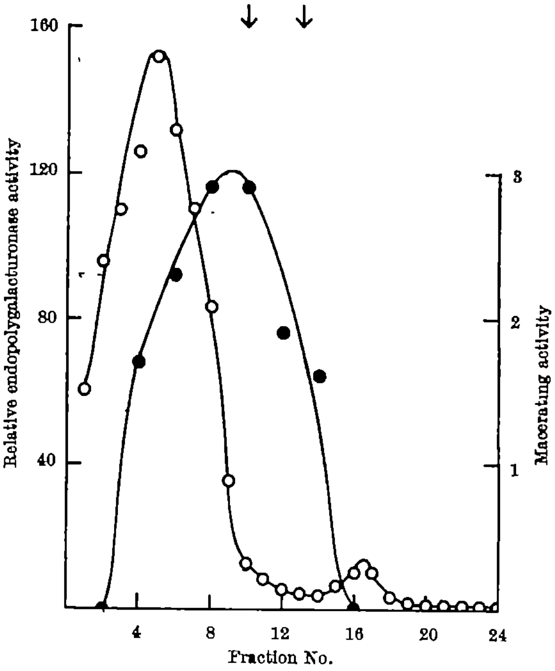

Fig. 1. Gel filtration on 'Sephadex *G*.75' of *S. fructigena* culture filtrate, showing endopolygalacturonase activity (○) relative to pectinol 10 M (1 mg/ml.) as 100. Macerating activity (●) is expressed as 100/*t*, where *t* is the mean time (min) for potato disks to lose coherence. Fractions 10–13 (within arrows) were applied to a second column (see Fig. 2)

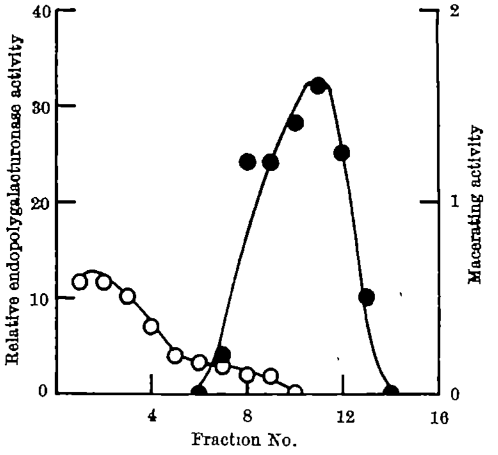

Fig. 2. Second gel filtration of 30 ml. sample. Symbols as in Fig. 1

Fractions 10–13 were re-applied to a shorter 'Sephadex' column, when a further separation of macerating and endopolygalacturonase activity was obtained (Fig. 2). Macerating activity (at *p*H 4·7) free of endopolygalacturonase was also obtained by passage of appropriate salt-free fractions from 'Sephadex' through a column of 'Ecteola'–cellulose[10], which retained the endopolygalacturonase. These preparations showed no polygalacturonase or polymethylgalacturonase activity (at *p*H 4·7), as assessed by the viscosity[11] and reducing group methods[12], while a test for pectinesterase[13] was also negative. The toxicity[14] of the crude culture filtrate to potato and cucumber slices was retained in the fractions showing macerating activity, supporting earlier views on the probable identity of macerating and toxic factors[4,15].

At present, we suggest the use of the term 'maceration factor' for this thermolabile active substance, in preference to 'protopectinase', since the latter term implies an enzymic nature, which we have failed to demonstrate: indeed, the level of protein in actively macerating percolates from 'Ecteola'–cellulose was below the limits of estimation by two methods[16,17]. The retardation of the maceration factor behind the main endopolygalacturonase peak suggests that it may be a smaller molecule[7]; there was also some evidence of adsorption effects between the maceration factor and endopolygalacturonase.

Plausibility of the Ribonucleic Acid Code

RECENT experimental results indicate that there is a correspondence between RNA trinucleotides and amino-acids. Specifically, for each of the 20 amino-acids, published data list at least one trinucleotide believed to incorporate it in the protein synthesis machinery of *E. coli*. Surprisingly, in each of these published code-words, the symbol U (uracil) occurs in at least one of the three positions.

A careful examination of the experimental procedures reveals that 'random' polynucleotide chains could only be tested if they contained a strong preponderance (at least 65–70 per cent) of the symbol U. Specifically, the trinucleotides containing no U were so much less probable than those containing U that even if some of these were good code-words, and consistently incorporated their specific amino-acids, the frequency of these acids would have been below the significance-level of the experiment. Other experiments have suggested that a very few U-free triplets, such as AAA and CCC, do not code for any amino-acid.

In the face of these results, it is natural to inquire: Is it not overwhelmingly probable that U is needed in most or all of the code-words? An affirmative answer to this question appears to be at variance with the fact that U is not nearly so preponderant in Nature as this would seem to imply.

One hypothesis might be that the 37 triplets containing U include the amino-acid code-words, while the other 27 triplets include the regulatory instructions for the genetic process. However, the facts so far are also consistent with the following model.

Suppose that each amino-acid is 'randomly' assigned three different trinucleotides which code for it. Thus 60 of the 64 triplets are used as code-words. If only 37 of the 64 triplets are 'observable', how many different amino-acids should be represented among the observable triplets?

For a familiar probabilistic formulation one may imagine a pack of 64 cards, including four 'jokers' and three each of the numbers 1–20. If 37 cards are selected at random, how many different numbers are expected to appear? In particular, how likely is it that all 20 numbers be represented at least once each?

The formula for the probability of exactly n different numbers in a hand of 37 cards from this pack of 64 is:

$$P_n = \binom{20}{n} \sum_{j=0}^{n-11} (-1)^j \binom{n}{j} \binom{3(n-j)+4}{37} \Big/ \binom{64}{37}$$

$$\text{for } 11 \leqslant n \leqslant 20$$

Clearly $P_n = 0$ for $n < 11$ or $n > 20$.

To an accuracy of $\pm$ 0·002, this leads to the data in Table 1.

Table 1

n	P_n
20	0·174
19	0·390
18	0·310
17	0·108
16	0·017
15	0·001
14	0·000

Thus, the odds of at least 19 distinct amino-acids being represented in a sample of 37 trinucleotides is better than an even bet; and the probability of at least 17 is a remarkable 98 per cent. The expectation of the distribution is 18·6 distinct amino-acids.

The principal conclusion from this calculation is that it is premature to reach firm conclusions about the role of the U-free trinucleotides.

Pasadena.

Deoxyribonucleic Acid Synthesis or Turn-over in Non-dividing Pollen Cells of Pine

INVESTIGATIONS of deoxyribonucleic acid (DNA) formation *in vivo* have shown that synthesis and replication are completed before separation of chromosomes begins. DNA synthesis, as measured by staining, incorporation of phosphorus-32, or radioactive nucleotide precursors, has generally been thought not to occur in cells unless they are preparing to divide[1]. Research leading to such conclusions has used developing angiosperm pollen cells (microspores) of *Lilium*[2] and *Tradescantia*[3] or bacteria and animal tissues[4].

Other investigations with bacteria[5], nematodes, and animal tissues[6] have indicated that synthesis or turnover of DNA may occur in non-dividing cells. This

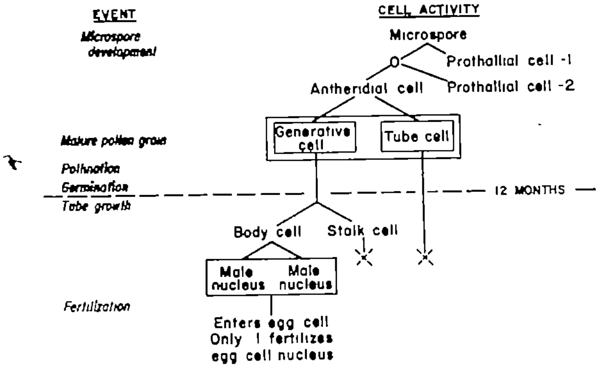

Fig. 1. Sequence of events in developing and germinating pine pollen

communication reports evidence that DNA synthesis or turn-over occurs in the tube nucleus of germinating pine pollen, a non-dividing plant cell.

Mature germinating pine pollen contains two functional nuclei: the tube nucleus, which does not divide, and the generative nucleus, which divides twice before fertilization. Developmental sequences of division in mature pine pollen are shown in Fig. 1. On germination the tube (vegetative) nucleus of the mature pollen moves down the tube. The tube nucleus disintegrates when the tube penetrates or contacts the egg cell. Some workers have claimed—on the basis of decreased staining of nucleic acid in the tube nucleus[7]—that the nucleus disintegrates while still in the tube before reaching the egg. The important fact, relative to this work, is that the tube nucleus is terminal and non-dividing.

We have studied incorporation of thymidine-methyl-^{3}H into germinating pine pollen. The labelling pattern obtained is shown in the autoradiogram in Fig. 2. Note that both the tube nucleus (*T*) and the generative nucleus (*G*) have incorporated tritiated thymidine. Table 1 summarizes experimental evidence that this represents incorporation and not mere absorption.

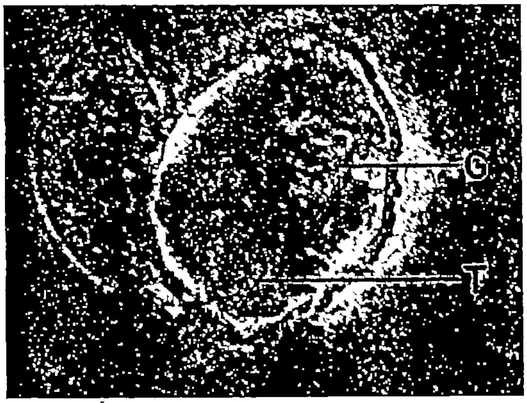

Fig. 2. Tritiated thymidine labelling in germinating pollen, *Pinus ponderosa* Laws. *T*, tube nucleus; *G*, generative nucleus. 100 mg pollen germinated 20 h, 29° C, in 10 ml of 0 002 M calcium phosphate buffer, *p*H 5 8, then for another 27 h in thymidine-methyl-^{3}H, 5 μc /ml culture solution (S A. 8 15 c./mμ) from New England Nuclear Corp, Boston. An equal volume ethanol–acetic acid (3 : 1) was added to each flask to inactivate and fix tissues. After 4 h new alcohol-acid solution was added for 8 h, followed by graded ethanol and butanol dehydration. During germination 'Mycostatin' (Squibb), 15 p p.m., was added as fungicide. Paraffin embedded grains were sectioned serially, about 8μ thick. Autoradiographic stripping film Kodak *AR* 10 was used

Table 1. Effect of DNase and RNase on Thymidine-^{3}H Incorporation in Germinating *Pinus ponderosa* Pollen

Treatment	Average No. of silver grains per section*		
	Generative nucleus	Tube (vegetative) nucleus	Cytoplasm of tube cell
Thymidine-^{3}H + buffer, *p*H 6 0	21	40	18
Thymidine-^{3}H + DNase	12	12	6
Thymidine-^{3}H + RNase	30	40	0

* The average count of 12–15 pollen sections. Pollen germinated and fixed as described under Fig. 2. Deoxyribonuclease and ribonuclease from Nutritional Biochemical Corp. 10 mg/100 ml., adjusted to *p*H 6·0 with sodium hydroxide. DNase solution contained 0 001 M magnesium sulphate. Incubation at 37° C for 1–4 h.

Counts were made of the number of silver grains visible in the emulsion exposed to prepared pollen sections. Results indicate that incorporated nucleoside is hydrolysed and removed by DNase but not by RNase. Washing with 10 per cent perchloric acid at 0° C did not remove activity incorporated in nuclei, although it did reduce the activity in cytoplasm. Cytoplasmic incorporation was also affected by RNase. This probably indicates that the apparent cytoplasmic incorporation actually represents free or entrapped, or merely terminally attached, thymidine-^{3}H rather than incorporation into DNA. Another possible explanation is that thymidine is being metabolized in the cytoplasm and the product is susceptible to hydrolysis by RNase and acids.

Why should the vegetative (tube) cell nucleus of pine pollen retain the capacity to synthesize or replace its DNA? We can only speculate about an answer. One hypothesis is that this daughter nucleus, derived from the same parent cell as the generative nucleus (Fig. 1), retains the ability to synthesize DNA but cannot divide. The sister generative cell, on the other hand, can both replicate its DNA and divide. Coulter and Chamberlain[8] cited a report which claimed to have observed a pine pollen tube nucleus which divided. The original paper reporting on a single preparation does not appear to convey this interpretation. Nevertheless, in terms of evolution and ontogenetic development, it is conceivable that the pine pollen tube nucleus may have the totipotency, under certain conditions, to divide as its sister generative cell does. Tulecke[9] has shown that the tube cell of *Ginkgo* pollen can divide and proliferate to produce a cell mass. This further supports the hypothesis of an inherent capacity of gymnosperm pollen tube cell and nucleus to divide under certain conditions.

A second hypothesis recognizes that a rapidly growing cell, such as a pollen tube, produces large amounts of enzymes as it develops[10]. This would require a great amount of RNA template. Possibly, such a growing tissue may have to synthesize or replace a certain amount of DNA. A relationship between high levels of DNA and respiration in anthers forming microsporocytes has been reported[11]. Thus in germinating pollen, which must rapidly increase the enzyme-level, it is conceivable that the level of cell DNA must be increased even if the cell will not divide. The tube nucleus appears actively to incorporate nucleotide components before the generative nucleus[12]. It also operates in an entirely different area of the cell, although the tube cell does produce large amounts of enzyme[10]. Thus its DNA-level may possibly have to be increased or replaced to support such activities. Replication of DNA and separation of the chromatids are two separate events. Synthesis or replacement of DNA may, under certain conditions, occur without separation and division following.

Steffenson and Bergeron[13] showed that the tube nucleus and sperm nuclei of *Lilium* pollen incorporated calcium-45 during tube growth. They suggested that the calcium absorbed was involved in DNA, and they interpreted this calcium absorption as indicating that DNA synthesis occurred in the tube nucleus of *Lilium* pollen. Their conclusion is not supported by others[14]. But if Steffenson and Bergeron are correct, their results would be similar to those reported here: an apparent incorporation or turn-over of DNA can occur in the tube nucleus. However, it seems from the investigation with calcium-45 that the tube nucleus is an active site of cell metabolism. Other plant cell nuclei have been shown to contain $4n$ and even $8n$ levels of DNA. This variation also indicates that DNA synthesis and chromosome replication can occur without nuclear or cell division[1,15].

In this work we followed standard criteria and procedures concerning incorporation of tritiated nucleosides into nucleic acids. Conclusions based on interpretation of these autoradiograms are probably valid. But we cannot be certain that what is called incorporation, through the techniques used, is not merely end-group fixation or short polynucleotide synthesis until the DNA of the tube nucleus is actually isolated and degraded, or some other direct critical analytical tool is used to show the location of the tritiated thymidine.

Cation–Anion Relationships in Italian Ryegrass (*Lolium multiflorum*)

SOIL, climate, time of sampling and other factors influence the mineral composition of plants, and the same species can contain a wide range of inorganic ions. In spite of these variations several workers[1–3], using different plants, claimed that the sum of the cations (expressed in m.equiv./100 g dry material) of a particular plant is constant. McCalla and Woodford[4] found that the ratio of total cations : total anions in wheat was constant and later Bear[5] showed that, for lucerne, at any pH when ions were expressed in m.equiv./100 g:

$$\frac{K + Na + Ca + Mg}{P + Cl + S + Si + N} = \text{a constant}$$

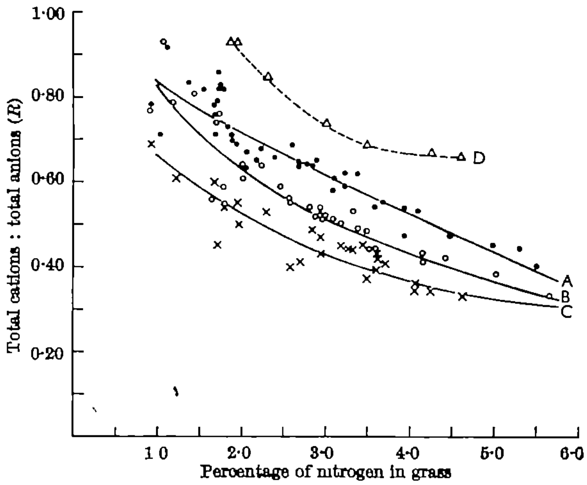

Fig. 1. Relationships between total nitrogen and total cation : anion ratio (R) in Italian ryegrass. ●, Curve A, samples grown in the field with no added nitrogen or with NO_3^- but without NH_4^+; ○, curve B, samples grown in the field with medium amounts of NH_4^+ (for example, 35–70 lb. nitrogen/acre as NH_4NO_3); ×, curve C, samples grown in the field with large amounts of NH_4^+ (for example, 40–160 lb. nitrogen/acre as $(NH_4)_2SO_4$); △, curve D, samples grown in one of the soils in the greenhouse in winter with NO_3^- but without NH_4^+

It is not known if silicon should be included, and Dijkshoorn[6], using perennial ryegrass, obtained a constant = 0·5 when silicon was omitted.

Italian ryegrass, consisting of 6 strains but mainly *S.*22, was grown on 20 soils throughout Britain in five seasons (1957–61); the grass received varying nitrogen–phosphorus–potassium fertilizer treatments and was cut at various stages of growth during the period April–September. More than 100 samples of the grass were analysed for the cations, K^+, Na^+, Ca^{++}, Mg^{++} and the anions, NO_3^- (assumed responsible for the uptake of all N), $H_2PO_4^-$, $SO_4^{=}$ and Cl^-. Silicon was also measured. The results give new information on cation–anion relationships in plants.

(1) The total cations in the grass ranged widely from 80 to 205 m.equiv./100 g dry grass.

(2) The total anions ranged from 130 to 551 m.equiv./100 g (including silicon) and 104 to 496 m.equiv./100 g (omitting silicon). In two groups of samples total cations were more closely correlated with total anions when silicon was omitted ($r = 0\cdot59^{***}$ and $r = 0\cdot69^{***}$ with and without silicon respectively in one group of 45 samples and $r = 0\cdot77^{***}$ and $0\cdot94^{***}$ in another group of 20 samples).

This means that including silicon complicates studies on cation–anion relationships unnecessarily; probably silicon does not enter plants as an ion. Iler[7] showed that there are few silicate ions below pH 9·0, which is above the pH of normal soil.

(3) The ratio of total cations : total anions in all samples was <1 but was not constant (silicon omitted), and ranged from 0·33 to 0·93.

Curves A–C in Fig. 1 show that the ratio of total cations : total anions (silicon omitted) depends on the nitrogen status of the grass and the type of nitrogen (that is, NO_3^- or NH_4^+) taken up by the plant. The relationships between total nitrogen of the grass grown in the field and total cation : total anion ratio (R) are expressed by the following equations:

(A) With no added NH_4^+.

$$R = 0\cdot890 - 0\cdot0936\,N + 0\cdot059/(N+\tfrac{1}{2})$$

(resid. $S.E.$ = ± 0·051)

Grass, receiving no nitrogen but containing much chlorine (> 1·5 per cent), is an exception, and its R value is obtained from equation C.

(B) With medium amount of NH_4^+.

$$R = 0{\cdot}479 - 0{\cdot}0441\ \mathrm{N} + 0{\cdot}606/(\mathrm{N}+\tfrac{1}{2})$$
$$(\text{resid. } S.E. = \pm\ 0{\cdot}053)$$

(C) With large amount of NH_4^+.

$$R = 0{\cdot}444 - 0{\cdot}0382\mathrm{N} + 0{\cdot}382/(\mathrm{N}+\tfrac{1}{2})$$
$$(\text{resid. } S.E. = \pm\ 0{\cdot}038)$$

Curve D shows that the ratio of total cations : total anions for any nitrogen-level is greater in grass grown in the greenhouse during winter than in grass grown in the open between April and September.

I thank M. J. R. Healy, Statistics Department. Rothamsted Experimental Station, for deriving the equations.

ENTOMOLOGY

Effect of Low Temperatures on Development, Hatching and Survival of the Eggs of *Aedes aegypti* (L)

THE resistance of insect eggs to cold can be an important factor governing the survival and distribution of the species. In the case of the eggs of *A. aegypti*, prolonged exposure to temperatures below 10° C was shown to be lethal[1]. In order to examine more precisely the effect of storage at a low temperature on embryonal development, ability to hatch and viability of the prolarval stage, eggs at various stages of development were transferred to lower temperatures for periods up to 50 days. Respiration-rate and response to hatching stimulus were examined before and after treatment in the cold. Each batch consisted of eggs laid on filter paper during a period of 12 h. 100 mg of air-dried eggs were placed in micro-cups, and the oxygen uptake was measured at 30° C in a conventional Warburg apparatus. Respiration was nearly constant during the time of the experiment for 4–6 h. No fluid was added to the cups, in order to prevent hatching. 0·1 ml. of 20 per cent potassium hydroxide was added to the central well. Hatching was induced by lowering the oxygen concentration in the submersion medium[2]. In order to avoid erratic response, maximum stimulus was applied by adding ascorbic acid (10^{-3} M final concentration) to the hatching vessels and placing them over pyrogallol in jars which were afterwards evacuated.

Water content was determined by the difference in weight of eggs taken directly from storage and after drying at 105° for 24 h. Fat was extracted with alcohol/ether (3 : 1) and esterified fatty acids were determined according to the method of Stern and Shapiro[3]. Respiration and percentage hatching of eggs stored at 28° C was examined daily for the first 9 days following oviposition and at intervals thereafter up to 8 months. During the first four days, the eggs were kept on filter paper saturated with water, in order to allow full embryonal development; thereafter they were transferred to relative humidity 70–90.

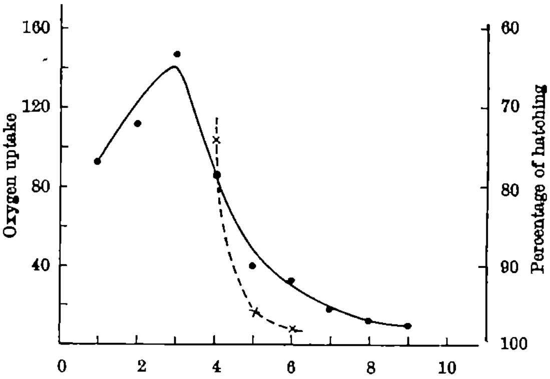

Fig. 1. Oxygen uptake in μl. × 10^{3}/h/mg air-dried eggs during embryonic development (solid line) at 28° C. Percentage of hatching (broken line)

As can be seen from Fig. 1, uptake of oxygen increases during an initial period of 3 days and then falls off steeply for 3 further days and more gradually thereafter. With the decrease in respiration, response to hatching stimulus commences and reaches a maximum after 3 days (90–100 per cent); this high level remains almost constant for about 3 months and then declines (Fig. 2). Thus the time-curve of hatching obtained is in agreement with the observations of Kliewer[4]. In addition, determination of fat and water content during the storage at 28° C and relative humidity 70–90 showed that both constituents decrease continuously; this effect can be correlated with the decrease in the percentage of hatching (Fig. 2). If on the sixth day following oviposition, that is, after the completion of embryonal development, the eggs are transferred to a lower temperature (4°) and then returned to 28° C, the following is observed: (a) Oxygen uptake remains nearly the same (34·4 μl. × 10^{-3}/h/mg after 20 days storage at 4° C as compared with 32·0 μl. × 10^{-3}/h/mg before storage in the cold) while that of eggs from the same batch kept continuously at 28° C drops to a much lower level (9·6 μl. × 10^{-3}/h/mg). (b) Immediately after the storage in the cold, almost no hatching can be induced (1·8 per cent hatching as compared with 95 per cent of eggs not subjected to cold treatment). (c) On further storage at 28°, the respiration

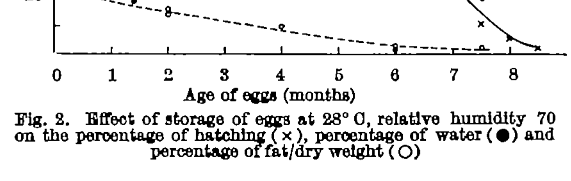

Fig. 2. Effect of storage of eggs at 28° C, relative humidity 70 on the percentage of hatching (×), percentage of water (●) and percentage of fat/dry weight (○)

decreases and after some days reaches almost the same level as that of the control kept constantly at 28° C. At the same time the response to hatching stimulus gradually returns. On the other hand, if the eggs are transferred to a lower temperature during the period of embryonic development, the following differences are observed: The respiration after exposure to cold is lower than before it, but again higher than that of the eggs not subjected to the cold treatment. However, no hatching can be induced even after the eggs have been returned to 28° C for a period of two weeks. The lower respiration at the end of the storage in the cold may be a reflexion of the onset of mortality.

These results indicate that there exists a reverse correlation between respiration of eggs and their hatching ability.

GENETICS

Incidence on Genetics of Mechanism of Segregation and Disjunction at Meiosis in Man

The explanation of the abnormal numbers of chromosomes observed in man rests on an eventual non-disjunction happening at the first or the second meiotic divisions or at both successively[1,2].

It seems primordial to remember that the two successive divisions of a normal meiosis are of different types: a reductional division which results in the segregation of homologous chromosomes and an equational division leading to the separation of the chromatids, already apparent at the diplotene stage of the first meiosis (tetrad).

So it is clear that non-segregation at the first meiosis (in our opinion erroneously called non-disjunction) must have a repercussion on the development of the second meiotic division.

We have thus computed a table with all the possible karyotypes of the gametes and combinations in the zygotes[3] and obtained the frequencies of the different combinations denoting by p_1 for women and by p_1' for men the probability of non-segregation at first meiotic division, that is, the probability that the two chromosomes of a given homologous pair will be drawn towards the same pole of the spindle, and by p_2 for women and p_2' for men the probability of non-disjunction at second meiosis, that is, the probability that the splitting of the centromere will be postponed until after the division is completed.

If one ignores the eventual degree of lethality of some combinations, the frequency of lethality being yet impossible to estimate, then the relations which link the frequencies of the different abnormalities, ought to be verified simultaneously by the observed frequencies.

The Turner's (*XO*) of paternal origin are twice more frequent than those of maternal origin, if we admit that the probabilities of non-segregation and non-disjunction are equal in both sexes ($p_1=p_1'$, $p_2=p_2'$). In this case, the total frequency of the Turner's is $3/4\ (p_1+p_2)$.

The Klinefelter's, with formula *XXY*, result from three gametic combinations (Table 1).

Table 1

Sperm	Ovum	Origin of abnormal gamete	Frequency
XXY	*O*	paternal and maternal	$\frac{p_1+p_2}{2} \times \frac{p_1' \times p_2'}{4}$ very rare
XY	*X*	paternal	$(1 - p_1 - p_2) \times p_1'/2$
Y	*XX*	maternal	$(1-p_1'-p_2') \times (p_1+p_2)/4$

When $p_1=p_1'$, $p_2=p_2'$, the total frequency of the Klinefelter's is $3/4\ p_1+p_2/4$.

We observe that, theoretically at least, Klinefelter's must be less frequent than Turner's and not equally frequent as stated by some authors[1].

On the other hand, one can easily deduce that the number of Klinefelter's of maternal origin increases with the value of p_2.

Values of p_1 and p_2 may be grossly estimated in the following way. The theoretical frequency of persons *XXY* in the general population is $(3p_1+p_2)/4$.

Observed values of patients with Klinefelter's syndrome (chromatin positive) are 1 : 1,000 males[4] and 1 : 400 males[5]. Admitting that: (1) $p_1=p_1'$ and $p_2=p_2'$; (2) there is no lethality for Klinefelter's syndrome; (3) Klinefelter's with chromatin positive are *XXY*, we obtain two equations:

$$(3p_1+p_2)/4=0{\cdot}0005 \qquad (a)$$

$$(3p_1+p_2)/4=0{\cdot}00125 \qquad (b)$$

These are represented in Fig. 1 by two straight lines (*a*) and (*b*).

The true values of p_1 and p_2 must lie between these lines. When $p_1=p_2$, the estimated values are $p_1=p_2=0{\cdot}0005$ (ref. 4) and $p_1=p_2=0{\cdot}00125$ (ref. 5) respectively, corresponding to the points *P* and *M*, lying on the bisections (Fig. 1).

Data on the frequency of Daltonism[6], the best marker gene for sex chromosomes yet known, will

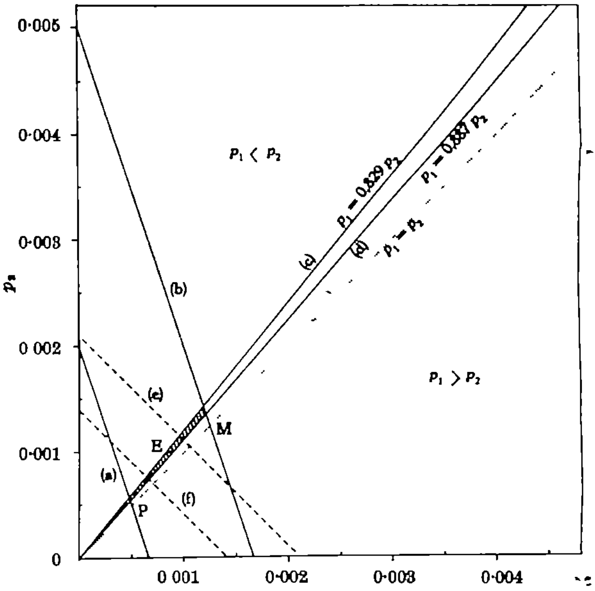

Fig. 1

permit us to give closer estimates of p_1 and p_2 and to decide whether p_1 is larger or smaller than p_2.

p being the frequency of the allele for Daltonism, we can obtain the probability for a Klinefelter to be of maternal or paternal origin and to have normal or abnormal colour vision.

Comparing the ratios:

$$\frac{\text{Klinefelter's of paternal origin}}{\text{Klinefelter's of maternal origin}} = \frac{2p_1}{p_1+p_2} = \frac{A}{B}$$

and

$$\frac{\text{colour-blind Klinefelter's of paternal origin}}{\text{colour-blind Klinefelter's of maternal origin}} = \frac{2p_1 \times p}{p_1 \times p + p_2} = \frac{C}{D}$$

we observe that:

(1) $A \gtrless B$ if $p_1 \gtrless p_2$;

(2) $C \gtrless D$ if $p_1 \times p \gtrless p_2$,

that is to say, if $p_1/p_2 \gtrless 1/p \approx 13$ for $p = 0{\cdot}082$ (Kalmus).

Consequently, if we suppose $p_1 = p_2$, the Klinefelter's of maternal origin must be as frequent as those of paternal origin, but colour-blind Klinefelter's of maternal origin must be 6·6 times more frequent as colour-blind Klinefelter's of paternal origin.

The actual investigations count, on a total of 106 chromatin-positive Klinefelter's (supposed to be XXY), two cases of a colour-blind son of normal parents and one case of a colour-blind son with normal father and colour-blind mother; this last case is of course extremely rare, the observed frequency of colour-blind women being only 0·004.

The values of p_1/p_2 estimated from these data are: 0·887 for the two colour-blind Klinefelter's with normal parents; 0·829 for all three colour-blind Klinefelter's.

We must have $0{\cdot}829 < p_1/p_2 < 0{\cdot}887$.

Combining relations between p_1 and p_2 based on frequencies of Klinefelter's in the population and on frequencies of colour-blind Klinefelter's, we find limits for the values of p_1 and p_2, respectively, the probabilities of non-segregation at first meiosis and non-disjunction at second meiosis. The acceptable values of p_1 and p_2 are the co-ordinates of the points lying on the hatched portion of Fig. 1, between the lines (c) and (d) of equations

$$p_1 = 0{\cdot}829p_2 \qquad (c)$$

$$p_1 = 0{\cdot}887p_2 \qquad (d)$$

E, the central point of this portion, corresponds approximately to:

$$p_1 = 0{\cdot}00085$$

$$p_2 = 0{\cdot}00100$$

which are our final estimates for p_1 and p_2. It must be observed that the real values will be higher than these estimated values if there is some lethality connected with XXY zygotes.

If we now replace p_1 and p_2 by their estimated values, the theoretical frequency of Turner's (XO) is $3/4(p_1+p_2) = 0{\cdot}0014$.

The observed frequency of the Turner's being estimated to 0·0001 in the population[7], we may conclude that at most one XO zygote in 14 survives.

If we use the observed frequencies of mongolism in the same way, and represent by p_1 and p_2 the probabilities of non-segregation and non-disjunction of the 21st pair of chromosomes (in men and in women), we have the relations:

$p_1 + p_2 = 0{\cdot}0021$ for the frequency given by Stevenson[8] (Fig. 1, line e);

$p_1 + p_2 = 0{\cdot}0014$ for the mean of values of frequencies quoted by Penrose[9] (Fig. 1, line f).

Admitting for a moment that the probabilities of non-segregation and non-disjunction are equal to those of the sex chromosomes, and replacing p_1 and p_2 by the estimated values 0·00085 and 0·00100 respectively, we find $p_1 + p_2 = 0{\cdot}00185$, a value situated between the two observed frequencies of mongolism. We wish to direct attention to the fact that the rate of lethality is greater in monosomy than in trisomy: this is true for chromosomes 21 as well as for the sex chromosomes.

We admit the provisional character of the proposed estimates of p_1 and p_2: we think the main interest of our work lies in a trial of quantification of a phenomenon as yet only considered qualitatively. We hope that inquiries in the future will provide data which will help to test the different hypotheses we have felt compelled to introduce in our reasoning.

PSYCHOLOGY

New Phenomena in Apparent Duration, Distance and Speed

OUR earlier experiments on interdependence in judgments of time, space and movement led to the establishment of a phenomenon, now known as the '*kappa*-effect', in visual and auditory experience[1]. These experiments prompted us to inquire whether analogous phenomena characterize judgments in other contexts when the subject himself undergoes movement, for example, as a passenger in a vehicle on the road.

The subjects travelled in groups of five or ten, in a closed van which precluded all visual cues of the route, or blindfold in a saloon car. A bell was rung at approximately the temporal mid-point of the journey. When the vehicle stopped at the end of the journey, the subjects estimated the pre-bell and post-bell duration, and half of the subjects then estimated the pre-bell and post-bell distance and half of them estimated the pre-bell and post-bell speed. In three trials, at different speeds, the vehicle accelerated when the bell rang; in three corresponding trials it decelerated when the bell rang; and in three trials the speed remained constant for the journey, although it varied from trial to trial. The full journeys lasted 12–30 min., with speeds ranging from 15 to 60 m.p.h. The distance covered was about 12 miles in each journey.

The main results may be grouped as follows:

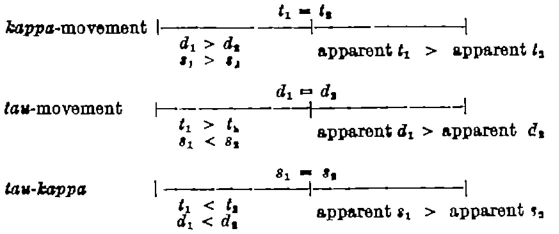
(1) Analysis of the estimates reveals an interdependence in apparent duration, distance and speed such that if two parts of a journey take the same clock time, that part will seem to last longer in which the distance and speed are greater. We propose to designate this the *kappa*-movement effect.

In the same situation, the shorter distance is overestimated and the longer distance, if anything, underestimated. From this, together with the *tau*-effect[2] (which demonstrates the dependence of spatial judgment on temporal factors), we may infer that if two parts of a journey are of equal distance, that part will seem of greater length which is travelled at a slower speed and for a longer time. This we propose to call the *tau*-movement effect.

Finally, in the same situation, the slower speed is over-estimated and the faster speed, if anything, under-estimated. From this, together with the *tau*-effect, we may infer that if two parts of a journey are travelled at the same speed, that part will seem faster in which the distance and time are shorter. This we designate the *kappa-tau*-effect.

The order of magnitude of the *kappa*-movement effect is about 25 per cent, within the range of values studied; the corresponding order of magnitude of the other two effects would seem to be much greater.

The effects may be represented diagrammatically,



(2) In comparing the estimates with the actual durations, distances and speeds, we find that, on the whole, speed is most accurately assessed, distance least accurately, with duration intermediate between the two. The speed which is most accurately estimated, retrospectively, is in the region of 32 m.p.h. At slower speeds, the traveller believes he has travelled faster than he actually has, and at faster speeds he believes he has travelled slower (Fig. 1).

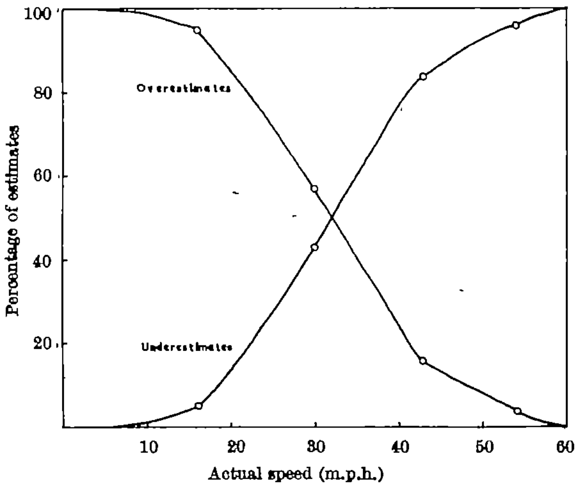


Fig. 1. Percentage of over-estimates and under-estimates of speed

(3) From any two estimates of duration, distance and speed, we can derive the third, and we can compare these derived values with the corresponding direct estimates. On making this comparison, we find that the distance our subjects believe they have travelled is less than that implied by their joint estimates of duration and speed, and conversely they believe they have travelled for a longer time and at a faster speed as judged by the derived estimates of duration and speed respectively.

We thank the Automobile Association for marking out stretches of highway and the Lancashire County and Manchester City Police for providing vehicles and drivers.

A Regional Difference in Expected Consumption Patterns

DURING the course of a survey of the aspirations and expectations of some 1,300 pupils about to leave school[1] the following questions were asked, in a questionnaire administered in the classroom:

> When you are earning there are probably various things you hope to save up for. What do you hope to own after you have been working for a year?
>
> When you have been working for about 9 or 10 years? What do you hope to own by the time you retire?

The respondents were in their final or penultimate year at school. They were drawn from schools in two main regions, a home county and a county in the south-west of England. Boys and girls came from separate schools. In the home county, secondary modern, technical and grammar schools were visited; in the south-west, modern and grammar schools.

For each of the main sub-samples, the average number of items given in reply to each of these questions was calculated. These figures are shown in two graphs (Fig. 1), illustrating an interesting difference in expected consumption pattern between the two regions.

It can be seen that there is an overall difference in relation to the early years, the home county mentioning a greater number of items. By retirement, there is little difference. The main point of interest, however, is that the south-west England county mentions more items on retirement than at the 10-year point, whereas the home county gives higher figures for the 10-year point than at retirement.

The first period specified, after one year of work, evoked items typical of young people starting work, such as 'a bicycle' or 'clothes'. There is, therefore, less point in comparing these figures with the other two sets, when the items mentioned were very alike for the two periods; predominantly 'a house' and 'a car'. It would seem that the young people in the home county have a greater expectation of accumulating such possessions fairly early (and perhaps paying for them while enjoying them for the remainder of their lives) whereas the expected pattern in the

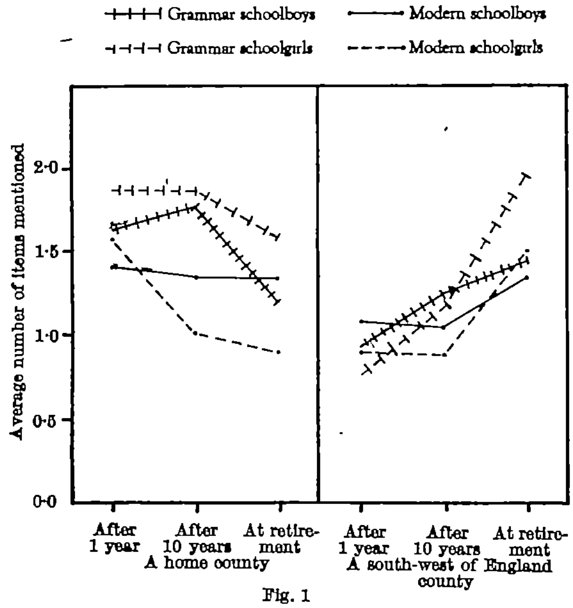

Fig. 1

south-west is to have, and to exercise, relatively greater purchasing power towards the end of the working life.

These findings are not drawn from representative samples. However, they are possibly of interest in that the pattern is repeated independently four times; and the drop from the 10-year period to retirement is repeated twice more, with the technical school boys and girls. These figures are not shown because of the absence of corresponding data for the south-west.

Traumatically Conditioned Responses acquired during Respiratory Paralysis

THIS communication describes a new technique for conditioning human subjects using a single traumatic stimulus. The need for such a stimulus arises in the conditioned aversive therapy of such behaviours as alcoholism and compulsions. Vomiting has been used frequently as an aversive stimulus[1,2] but suffers from two disadvantages: the onset of vomiting is difficult to predict so that the moment at which the conditioned stimulus must be presented to ensure optimal conditioning is uncertain; also vomiting is accompanied by many undesirable side-effects. An alternative technique, which avoids these disadvantages, is provided by a temporary suppression of respiration, induced by succinylcholine chloride dihydrate ('Scoline').

Experimental traumatic conditioning has been carried out with animal subjects, for example, Solomon and Wynne[3] have shown how conditioned avoidance responses may be formed in dogs by subjecting them to near-tetanizing electric shock. There are no comparable data derived from human subjects. Human subjects are influenced in their judgments of what is painful by adventitious stimuli[4], and in no case has the pain produced the massive autonomic and muscular reactions which have been found in animals. Experiments on 'psychological' trauma encounter similar difficulties: not all the subjects find the treatment traumatic and the physiological arousal is generally slight. The *ex post facto* investigation of individuals who have been in peril of their lives is the only other source of information about the effects of traumata[5].

The consequences of traumatic stimulation have an important place in a number of psychological systems. Some neurotic behaviour is thought to follow from a single traumatic event, and conditioned 'anxiety' responses are utilized in theories of personality though little is known about the generalization and extinction properties of the autonomic events on which 'anxiety' is usually predicated[6]. The technique described in this communication offers a means of providing experimental data relevant to these points.

'Scoline' is a curarizing drug which acts at the motor endplate of the efferent neurones serving the skeletal muscles to cause a nerve-muscle block. For a short period following the injection of 'Scoline' each subject is totally paralysed, unable to move or breathe. During the paralysis the subject remains fully conscious. All the subjects, including some who have themselves given 'Scoline', say that the experience is harrowing to a degree.

The following technique has been used in an investigation of the ability of alcoholic patients to form conditioned responses based on suppression of respiration. The conditioned stimulus was a 600 c/s tone at 70 db. A continuous record of psychogalvanic skin response, respiration, heart-rate and muscle tension was made; these four variables served two purposes: they were used as indices of the conditioned and unconditioned responses, and they were also used to monitor the course of the paralysis. Each subject was first given 1/150 of a grain of 'Atropine' to prevent excess salivation: this dose was injected into a saline drip. The dose of 'Scoline' (20 mg) was given afterwards in the same way. In no case did a subject know from extraneous stimuli that any drug had been given. During the first part of the experiment the subjects were habituated to the tone which they heard through headphones; the tone sounded for five seconds with an average interval of one minute between each presentation. When no response had been made to the tone for five consecutive presentations of the tone the 'Scoline' was given. The tone was presented throughout the period in which no regular respiratory response could be observed on the polygraph. 5 min after the restoration of respiration each subject was given a series of extinction trials. Similar sequences of extinction trials were given one week and three weeks later.

The results of the conditioning procedure indicate that the simultaneous occurrence of respiratory paralysis and tone leads to the formation of conditioned responses. A conditioned response was defined as a change of physiological function following the tone in an interval less than the latency of a 'startle' response. In the extinction trials given immediately after the conditioning trial two out of ten subjects extinguished; in the extinction trials given one week and three weeks later all the ten subjects showed conditioned responses. Table 1 shows the results of 5 subjects who were given identical series of 100 extinction trials. There is very little variation between the subjects in the number of responses given during extinction although, during the initial habituation period, the subjects exhibited marked differences.

Table 1. Number, latency and size of responses given to the conditioned stimulus by 5 male subjects. *a*, during habituation; *b*, in 30 trials immediately following conditioning; *c*, in 30 trials one week later; *d*, in 40 trials three weeks later, *e*, total for 100 trials (latency of response (in seconds), size of responses in ohms)

	a	*b*	*c*	*d*	*e*
Mean No. of responses	13·6	28·0	30·0	38·0	94 0
S.D.	11·0	2 8	0·0	4·5	4·2
Mean latency of responses	2·58	2·3	2·01	1·91	—
S.D	0·28	0 22	0·18	0·17	—
Mean size of responses	658 6	385·8	1,384·0	1,877·2	—
S.D	418·0	131·2	931·4	1,685·3	—

The latency of the conditioned response decreased and its size increased during the interval between the series of extinction trials. These results suggest that conditioning based on a traumatic event leads to responses which exhibit characteristics of an opposite sort to those found in the other conditioning procedures which have been applied to human subjects. In particular the increasing strength of the conditioned response as time passes provides experimental support for the clinically derived notion that 'anxiety' may be a permanent consequence of such a traumatic event.

We thank the Ontario Alcoholism Research Foundation for support of this work.

STATISTICS

An Iterative Method for obtaining Statistical Frequency Distributions

Nilakantan and Achar[1] have recently described an iterative method for obtaining approximations to frequency distributions from limited data. No attempt was made to provide a theoretical justification of the procedure. In view of the many possible applications of the method it appears worth while to discuss its justification and limitation.

Adopting the notation of Nilakantan and Achar, let x denote discrete variations of a quantity from its arithmetic mean and let F denote the frequency of occurrence of the discrete values of x. Let Y denote the Gaussian probability distribution:

$$Y = \frac{1}{s(2\pi)^{1/2}} \exp(-x^2/2s^2) \qquad (1)$$

where s is a constant.

The probability with which Y predicts a given set of frequencies F is proportional to:

$$p = \frac{1}{(2\pi)^{n/2}s^n} \exp(-\Sigma nFx^2/2s^2) \qquad (2)$$

which is a maximum when:

$$s = (\Sigma Fx^2)^{1/2} = \text{standard deviation } \sigma. \qquad (3)$$

The resulting Y may be denoted by F_1.

Nilakantan and Achar then replace F in equation (3) by $(F+F_1)/2$ and hence compute a new s, say σ_1, which maximizes equation (2) in which F is replaced by $(F+F_1)/2$. The σ_1 is substituted for s in equation (1) in order to obtain a further distribution F_2. Replacement of F in equation (3) by $(F_1+F_2)/2$ similarly leads to a quantity σ_2 and a frequency F_3. In the example provided by Nilakantan and Achar a given set of frequencies F is used for deriving curves F_1 and F_{10}, it being claimed that F_{10} forms a close approximation to the frequencies obtained by choosing a larger number of samples. The process converges rather slowly, leading to $\sigma_8 = 1{\cdot}34$ and $\sigma_9 = 1{\cdot}29$. A set of data containing five times as many samples as was used to compute F was found to have a frequency distribution very close to F_4 for which $\sigma_3 = 1{\cdot}54$.

The validity of the procedure may be examined as follows: the Gaussian function which best predicts the observed set of n samples F is F_1. The frequencies of a hypothetical second set of n samples is therefore best predictable by F_1. For a total of $2n$ samples of which the first n are known to be distributed according to F and the second set are assumed to be distributed according to F_1 the frequency distribution would be $(F+F_1)/2$. The Gaussian function which best predicts this is F_2, and so a third set of samples would be best predicted by F_2. For a total of $2n$ samples of which the first n are of the second set and the second n are of the third set the frequency distribution would be $(F_1+F_2)/2$. The Gaussian function which best predicts this is F_3 and so a fourth set of samples would be best predicted by F_3. Continuing the argument leads to F_4, F_5, etc., to predict the distributions of successive sets of n samples.

The functions F_1, F_2, etc., are thus the Gaussian distributions which best predict certain hypothetical sets of data of which only the first set represents observed data. The assumption that the hypothetical sets become increasingly more typical of actual data is difficult to justify. It would appear that either of

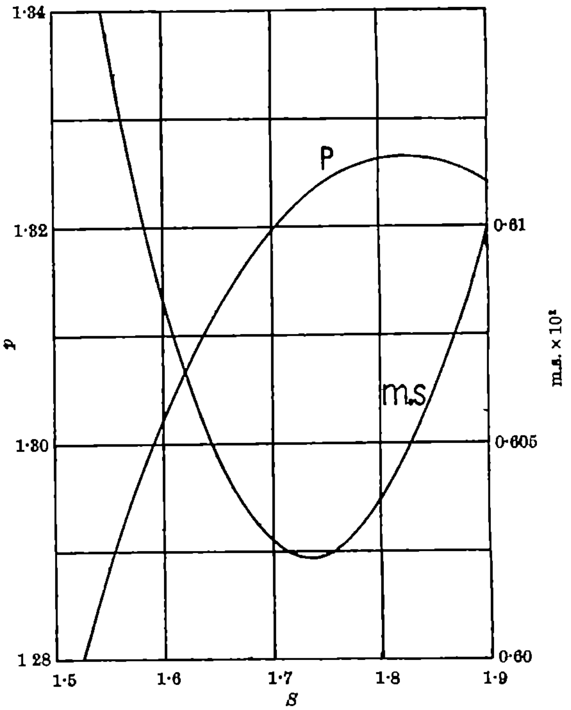

Fig. 1. The probability p according to equation (2) and the mean square (m.s.) difference between Y of equation (1) and the observed frequencies F

the following assumptions are more capable of justification:

Assumption 1: The derived probability distribution, in this instance Gaussian, must have its parameters chosen to give the highest probability to the observed data F.

Assumption 2: The derived distribution must have its parameters chosen to best approximate, in the sense of mean square error, the observed data F.

For different values of s the quantity p of equation (2) is plotted in Fig. 1 for the data of Nilakantan and Achar. Assumption 1 is of course best satisfied when $s = \sigma = 1{\cdot}83$. The mean square difference between Y of equation (1) and F is also shown as a function of s in Fig. 1. It follows that assumption 2 is best satisfied when $s = 1{\cdot}73$.

It is clear from Fig. 1 that the method of Nilakantan and Achar, which leads to $\sigma_9 = 1{\cdot}29$, produces a probability distribution in very poor agreement with either of assumptions 1 and 2. This result, together with the fact that Nilakantan and Achar obtained experimental agreement with σ_3 rather than σ_9, leads me to conclude that their method should be used with considerable caution and only when there are sufficient samples available to permit a check on the validity of the assumed limiting process.

H. S. Heaps

Nova Scotia Technical College,
Halifax, Canada.

---

[1] Nilakantan, P., and Achar, B. N., *Nature*, 193, 1005 (1962).

Since when two samples from a population are combined we get a larger and more representative sample, the iterative process could, in effect, be considered as a means of obtaining a larger sample starting from a small one. As the distribution curve F_2 is derived from the mean values of the frequencies in F and F_1, that is, $(F+F_1)/2$, the result of the combination of two sets of data, namely, the actual curve obtained from n experiments and its Gaussian counterpart, may be regarded as being representative of $2n$ experimental observations (Fig. 1). On the same basis, we may regard F_3 (derived from F_2 and F_1) as representing $3n$ experimental observations and F_4, $5n$ experimental observations. Thus the sample size may be considered as increasing in the following sequence, namely, $n, n, 2n, 3n, 5n, \ldots 89n, \ldots$ corresponding to $F, F_1, F_2, F_3, F_4, \ldots, F_{10}$ and so forth. The $(n+1)$th term in this sequence is given by

$$n\left[\frac{1}{2}\left\{1+\frac{1}{\sqrt{5}}\right\}\left\{\frac{1+\sqrt{5}}{2}\right\}^n+\frac{1}{2}\left\{1-\frac{1}{\sqrt{5}}\right\}\left\{\frac{1-\sqrt{5}}{2}\right\}^n\right]$$

We have since found that a more rational procedure would be to use $\frac{nF+nF_1}{2n}$ instead of $\frac{F+F_1}{2}$ to get F_2, $\frac{nF_1+2nF_2}{3n}$ instead of $\frac{F_1+F_2}{2}$ to get F_3, and so forth. The results obtained by this modification are, however, not significantly different from those obtained previously. But the latter procedure may be considered more logical as indicative of the increase in equivalent sample size.

The iterative process is seen to converge slowly at first, but more rapidly later as may be expected, since the 'equivalent' or effective sample size also increases.

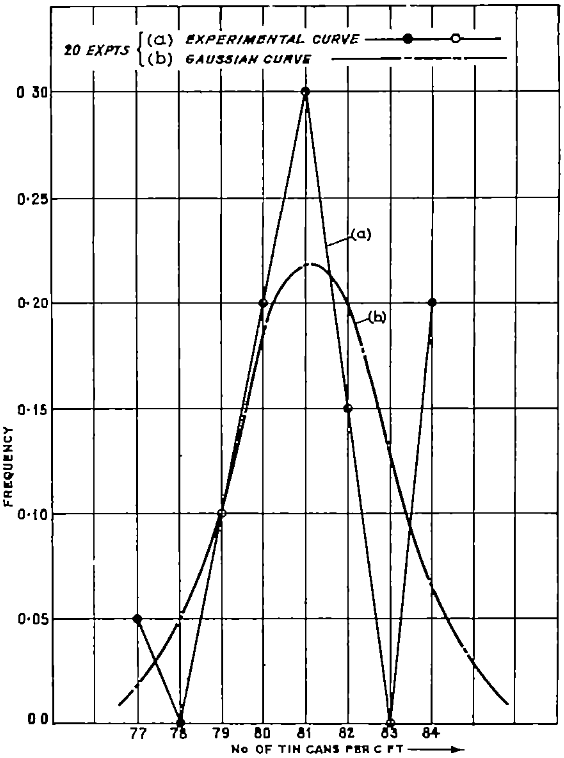

Fig. 1. Frequency distribution curves

Prof. Heaps has assumed that the parameters of the Gaussian distribution curve must be so chosen that they should either give the highest sample probability to the observed data or form the best approximation to the observed data in the sense of mean square difference. He finds that in the case of the experiments carried out by us, $s = 1{\cdot}83$ would give the highest sample probability for the observed data for 20 experiments, whereas $s = 1{\cdot}73$ would give the least mean square difference. As σ_9 obtained from the iterative method has a value 1·29, which is different from either of these, he concludes that the method should be used with caution.

As the Gaussian distribution curve, F_1, has been fitted to the observed data, F, by obtaining the standard deviation $\sigma = 1{\cdot}83$ from the observed data, the first assumption made by Heaps is self-evident, as this value maximizes the sample probability function 'p' which is a characteristic of the size of the sample considered, that is, 20 in the present case. However, in the iterative method the sample size should be regarded as increasing with successive iterations and different 'p' functions would have to be used. Hence $\sigma_9 = 1{\cdot}29$, which would maximize the 'p' function corresponding to an 'effective' sample size of 1,780, is not inconsistent with $\sigma = 1{\cdot}83$ maximizing 'p' for a sample size of 20. The difficulty experienced by Heaps in fitting the results of the iterative method with his assumptions is thus understandable since the variation of the effective sample size was not taken into account by him.

We agree that a considerable amount of experimental investigation will be necessary to establish the general applicability of the method and its possible limitations. We are continuing our investigations on these aspects.

Generalized Hartley–Ross Unbiased Ratio-Type Estimator

RATIO method of estimation is frequently used in sample surveys to estimate the population mean of the variable under investigation. Several ratio-type estimates can be formed. All these estimates are unsatisfactory in the sense that they are biased. This difficulty was overcome by Hartley and Ross[1], who proposed an unbiased ratio-type estimator for uni-stage sampling designs. In practice, however, we are generally faced with multi-stage sampling designs. This communication gives a generalized form of Hartley–Ross unbiased ratio-type estimator for multi-stage designs. Let N = number of first-stage units in the population, M = number of second-stage units in each of the first-stage units, P = number of third-stage units in each of the second-stage units, $Yijk$ = the value of the variable under investigations for the k-th unit in the j-th second-stage unit of the i-th first-stage unit, and

$$\bar{Y}ij. = \frac{1}{P}\sum_{1}^{P} Yijk,\ \bar{Y}i.. = \frac{1}{MP}\sum_{1}^{M}\sum_{1}^{P} Yijk \text{ and}$$

$$\bar{Y}... = \frac{1}{NMP}\sum_{1}^{N}\sum_{1}^{M}\sum_{1}^{P} Yijk$$

To estimate the population mean $\bar{Y}...$, a simple random sample of n first-stage units is selected. From each of the selected first-stage units, a simple random sample of m second-stage units is selected while from each of the selected second-stage units, a simple random sample of p third-stage units is drawn. Let $Xijk$ be the value of the auxiliary variable corresponding to $Yijk$, $Vijk = \dfrac{Yijk}{Xijk}$ and the quantities $\bar{X}ij.$, $\bar{X}i..$, $\bar{X}...$, $\bar{V}ij.$, $\bar{V}i..$ and $\bar{V}...$ be defined similarly.

Further, let

$$Sijrx = \frac{1}{p-1}\sum_{1}^{p}(Vijk - \bar{V}ij(p))\,(Xijk - \bar{X}ij(p))$$

$$Sirx = \frac{1}{m-1}\sum_{1}^{m}(\bar{V}ij(p) - \bar{V}i(mp)\,(\bar{X}ij(p) - \bar{X}i(mp))$$

$$Sbrx = \frac{1}{n-1}\sum_{1}^{n}(\bar{V}i(mp) - \bar{V}nmp)\,(\bar{X}i(mp) - \bar{X}nmp)$$

$$\bar{S}wrx = \frac{1}{n}\sum_{1}^{n} Sirx$$

$$\bar{\bar{S}}wrx = \frac{1}{nm}\sum_{1}^{n}\sum_{1}^{m} Sijrx$$

where $\bar{V}ij(p)$, $\bar{V}i(mp)$, $\bar{V}nmp$, $\bar{X}ij(p)$, $\bar{X}i(mp)$ and $\bar{X}nmp$ are the corresponding sample means.

Then an unbiased ratio-type estimate of $\bar{Y}...$ is given by

$$\text{Est } \bar{Y}... = \bar{V}nmp\,\bar{X}... + \frac{N-1}{N}Sbrx + \left[\frac{m-1}{m} + \frac{M-m}{Mm}\cdot\frac{1}{N}\right]\bar{S}wrx + \left[\frac{p-1}{p} + \frac{P-p}{Pp}\cdot\frac{1}{NM}\right]\bar{\bar{S}}wrx$$

If all the third-stage units in a second-stage unit have the same value, that is, $Yijn = \bar{Y}ij.$, we obtain the unbiased ratio-type estimate for two-stage designs, namely:

$$\text{Est } \bar{Y}.. = \bar{V}nm\,\bar{X}.. + \frac{N-1}{N}Sbrx + \left[\frac{m-1}{m} + \frac{M-m}{Mm}\cdot\frac{1}{N}\right]\bar{S}wrx$$

If, in addition, all the second-stage units in a first-stage unit have the same value, say, $\bar{Y}ij. = \bar{Y}i..$, we obtain the unbiased ratio-type estimate given by Hartley and Ross[1], namely,

$$\text{Est } \bar{Y}. = \bar{V}n\,\bar{X}. + \frac{N-1}{N}Sbrx$$

The general form of an unbiased ratio-type estimator for a t-stage design is now obvious and can be written down easily by induction.

MISCELLANEOUS

'Absolute' Age: a Meaningless Term

I WISH to appeal to my fellow geologists and workers in the rapidly growing subject of geochronology to discontinue a habit or fashion which is both unnecessary and misleading. I refer to the habit of calling radiometric ages 'absolute' ages. An age does not become 'absolute' by virtue of being expressed in units of time such as a year. If 'absolute' means anything at all, it implies complete independence of all events and relationships. But a year is a relationship and, moreover, our conviction that one year equals another is merely a convenient pragmatic hypothesis. As St. Augustine recognized long ago, there can be no real standard of time as there is of length or space, since the 'time' taken by an event passes away and cannot be brought back to be measured, as a metre rod can be measured by placing it alongside a standard metre rod. Yet we do not go out of our way to say that the 'absolute' length of the rod is one metre. Nor if you ask a man of forty-five how old he is, does he reply "My absolute age is forty-five years".

The term is not only redundant and both philosophically and scientifically without meaning: it is also misleading in its psychological suggestion of a higher degree of accuracy than can be justified. A good example has recently appeared in *Nature*[1], where the title of a particularly welcome contribution begins "Confirmation of the Absolute Age . . .". Now how, if an age is 'absolute', can it require confirmation?

If any of the culprits claim that they are in good company with Newton and Kelvin, who both wrote of 'absolute time', they have only to remember Einstein and the coming of relativity. When it is desirable, as it sometimes is, to distinguish between geological age and the age expressed in years, the latter (except when measured by counting varves) can appropriately be called the 'radiometric age', a term that has already appeared occasionally in the literature of geochronology.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

CHEMIST, Principal Scientific Officer or Senior Scientific Officer grade (with a first- or second-class honours degree, or equivalent, in chemistry and several years postgraduate experience in an appropriate field) at Headquarters, London, to initiate and progress research programmes to provide aircraft lubricants, fuels and hydraulic fluids of improved performance; to undertake liaison work in the related research and development fields (including test methods) with the aeronautical and oil industries; and to prepare and maintain specifications for the materials concerned—Ministry of Aviation, Est. 2/3.A.3, Room 516, Adelphi, John Adam Street, London, W.C.2, quoting Ref. HC/2D/852 (December 31).

CYTOLOGIST (with a good honours degree in science or medicine, and preferably experience in tissue culture and modern mammalian chromosome techniques)—The Director, Population Genetics Research Unit, Medical Research Council, Old Road, Headington, Oxford (December 31).

SPECIALIST MICROSCOPIST (with a first- or second-class honours degree in botany or an equivalent research qualification, a sound training in general chemistry and experienced in the application of modern microscopic techniques), to supervise a small team engaged in routine study of botanical and biological materials, and to take up the study of the microscopy of man-made and other fibres, etc.—The Government Chemist, 13 Clement's Inn Passage, London, W.C.2, quoting E/AR/010 (December 31).

RESEARCH FELLOW (with an honours degree in botany or agriculture majoring in pasture ecology, crop husbandry or agricultural botany) IN PASTURE ECOLOGY (Agrostology) at the University College of Rhodesia and Nyasaland, to initiate and carry out studies on grasses used in sown pastures in Rhodesia, as a member of a pasture ecology research team—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (January 10).

ASSISTANT LECTURER and a LECTURER IN APPLIED MATHEMATICS—The Registrar, The University, Nottingham (January 12).

CHAIR OF CLINICAL CHEMISTRY—The Secretary, The University, Edinburgh (January 14).

LECTURER or ASSISTANT LECTURER IN APPLIED MATHEMATICS, NUMERICAL ANALYSIS AND COMPUTING, OR STATISTICS—The Registrar, The University, Nottingham (January 14).

PROFESSOR AND HEAD OF THE ELECTRICAL ENGINEERING DEPARTMENT—The Assistant Registrar, Kwame Nkrumah University of Science and Technology, 15 Gordon Square, London, W.C.1; or The Registrar, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana (January 15).

PROFESSOR AND HEAD OF THE MECHANICAL ENGINEERING DEPARTMENT—The Assistant Registrar, Kwame Nkrumah University of Science and Technology, 15 Gordon Square, London, W.C.1; or The Registrar, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana (January 15).

SCIENTIFIC INFORMATION OFFICER (with a botanical or agricultural degree, the ability to write correct English and a knowledge of German or other foreign language), for work which includes the abstracting and reviewing of biological literature—The Director, Commonwealth Bureau of Plant Breeding and Genetics, School of Agriculture, Cambridge (January 15).

ASSISTANT IN CHEMISTRY, with duties primarily in organic chemistry, in St. Salvator's College—The Secretary, The University, College Gate, St. Andrews (January 19).

ASSOCIATE PROFESSOR IN EXPERIMENTAL PSYCHOLOGY; and a LECTURER IN PSYCHOLOGY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 25).

DEPUTY LIBRARIAN (with a good honours degree and experience of work in a university library, and preferably professional qualifications) OF THE UNIVERSITY LIBRARY, Newcastle upon Tyne—The Secretary, King's College (University of Durham), Newcastle upon Tyne (January 31).

LECTURER or SENIOR LECTURER (preferably with experience in the physico-chemical study of macromolecules) IN PHYSICAL CHEMISTRY at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 31).

LECTURER (qualified in mathematical statistics) IN STATISTICS—The Secretary of University Court, The University, Glasgow (January 31)

RESEARCH FELLOW (with a degree in science, medicine or veterinary science, postgraduate experience in research, and a working knowledge of the parasitic arthropods) IN PARASITOLOGY—The Registrar, University of Queensland, Brisbane, Queensland, Australia (January 31).

SENIOR LECTURER; and LECTURERS (2) IN THE SCHOOL OF PHYSICS, University of Sydney—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 31).

SENIOR LECTURER IN GEOLOGY (Petroleum Geologist) (January 31); a LECTURER IN CHEMISTRY (January 11); a LECTURER IN PHYSICS (January 4); and a LECTURER IN ZOOLOGY (January 4) at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (applications close on the dates shown in parentheses).

SENIOR LECTURER or LECTURER (with an honours, or higher degree, or other approved higher qualifications, and preferably some teaching experience) IN MATHEMATICS at the South Australian Institute of Technology, Adelaide—The Agent-General for South Australia, Strand, London, W.C.2 (January 31).

SENIOR TUTOR/DEMONSTRATOR (with a degree in science or engineering and some teaching and/or computer experience) IN THE BASSER COMPUTING DEPARTMENT of the School of Physics, University of Sydney—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 31).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS IN CHEMISTRY, BIOLOGICAL CHEMISTRY, ENGINEERING, PHARMACOLOGY, PHYSICS or in a related subject—The Registrar, The University, Bristol 8 (February 1).

PROFESSOR AND HEAD OF THE DEPARTMENT OF PHYSICS—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (February 8).

PROFESSOR OF PSYCHOLOGY—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (February 8).

ASSISTANT (preferably with an interest in the biochemistry of micro-organisms) IN BIOCHEMISTRY—The Secretary of University Court, The University, Glasgow (February 15).

LECTURER IN THE DEPARTMENT OF BIOCHEMISTRY—The Registrar, The University, Liverpool 3, quoting Ref. CV/211/N (March 1).

ASSISTANT PROFESSORS; ASSOCIATE PROFESSORS and PROFESSORS IN THE DEPARTMENT OF MATHEMATICS—Prof. M. Wyman, Mathematics Department, University of Alberta, Edmonton, Alberta, Canada.

ASSISTANT SENIOR CHEMIST (with a degree in chemistry or equivalent qualification, experience in modern analytical techniques and preferably experience in the treatment and disposal of effluents) in the Central Laboratories of the West Midlands Gas Board, Nechells, Birmingham—The Personnel Manager, West Midlands Gas Board, 5 Wharf Lane, Solihull, Warwickshire.

ASSOCIATE PROFESSOR IN MATHEMATICS; an ASSISTANT PROFESSOR IN PHYSICS; and an ASSISTANT PROFESSOR IN BIOCHEMISTRY—The Chairman, Division of Natural Sciences, University of Saskatchewan, Regina Campus, Regina, Saskatchewan, Canada.

LECTURER (with an interest in physical metallurgy) IN CHEMICAL ENGINEERING at the University of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

MATHEMATICS MASTER (with a first-class degree)—The Head Master, Westminster School, 17 Dean's Yard, Westminster, London, S.W.1.

READER (with substantial research experience) IN CONTROL SYSTEMS ENGINEERING IN THE DEPARTMENT OF ELECTRICAL ENGINEERING—Dr. J. H. Calderwood, Royal College of Advanced Technology, Salford 5, Lancs.

RESEARCH ASSISTANT (with a medical or science degree) IN THE SURGICAL UNIT, to work on human tumours in tissue-culture and the effects on them of chemotherapeutic agents—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2.

RESEARCH ASSISTANTS and GRADUATE TEACHING ASSISTANTS (students studying for degrees of Ph.D. and M.Sc. in chemistry)—Dr. H. E. Gunning, Head, Department of Chemistry, University of Alberta, Edmonton, Alberta, Canada.

RESEARCH ASSISTANT (B.Sc., preferably with experience of radioactive isotope tracer work) IN THE MEDICAL UNIT, to engage in studies of calcium metabolism—The House Governor, St. Mary's Hospital, Paddington, London, W.2.

APARTHEID IN SOUTH AFRICAN LEARNED SOCIETIES

MINERVA *, a review of science learning and policy, which replaces *Science* and *Freedom*, aims at improving our understanding of the effect of contemporary developments in every sphere of life on the pursuit of truth through science and scholarship, and of what science and scholarship are doing to themselves and to the rest of their society and the world beyond it. By thus improving understanding it hopes to make scientific and academic policy more reasonable and more realistic. The comparison and criticism of experience should promote more daring and judicious policy, stimulate the imagination and discourage efforts doomed to failure. The protection of the creative powers of science and scholarship generally is assisted when the conditions of their vitality are analysed and defined.

These aims are set forth and discussed at some length by the editor in an opening article which displays the way in which Government and science and scholarship interact in the world to-day and how their very growth is largely responsible for the pressures which arise and which, on the side of the university or the research institute, for example, may endanger the very conditions which have made scientific advance so rapid and fertile. Even the brief list of the problems arising in the relations between Government and science given in this opening article indicates how wide is the field with which it is proposed to deal in the new quarterly. The political relations of research and higher learning have undoubtedly become more sensitive in recent years, and there is ample room for such a forum as *Minerva* hopes to provide in which these problems can be analysed critically and seriously.

It is a strange coincidence that the first issue of *Minerva*, which includes the text of Sir Eric Ashby's Chancellor's Lecture to the University of the Witwatersrand, should have been published almost simultaneously with a most disturbing development of the South African Government's policy of apartheid (see *Nature*, 196, 201; 1962). It was announced on December 5 by the Minister of the Interior and of Education, Arts and Science, at a conference of librarians in Pretoria, that the South African Cabinet has decided that there is to be no mixed membership in scientific and professional organizations; where this exists separation must take place immediately. Non-European associations must be linked with national bodies by way of affiliation, naming one or two representatives to attend periodic and defined executive meetings called by the national associations of European organizations. This, the Minister naïvely suggested, would establish channels of contact for the exchange of ideas.

No other remark could better display the South African Government's indifference to the conditions on which the progress of science and learning generally depends or its steadfast repudiation of the very basis of a civilized community. To that attitude Sir Eric Ashby's lecture, for all that he carefully abstained from direct comment, gave unqualified condemnation. What he said of the university is largely relevant to the learned society and the professional association. The maintenance of standards of professional competence and learning is their responsibility; the conditions of admittance to membership are for them, and for them alone, to determine.

Some highly pertinent passages in this opening article in *Minerva* put the real issue admirably. "The claims which government makes on scientists and scholars to contribute to the general welfare and progress must be honoured, but the world of learning would serve neither society nor itself if it fails to scrutinize those claims with the same measure of critical discrimination that it applies to its own internal problems. The claims of society must always be examined with regard to their impact on the primary aims of science and scholarship. The claims of government must be examined to see whether they really are conducive to the welfare and progress of society, and scientists and scholars must not allow their judgment to be dominated by the thought of the public honour or material advantage which comes from the service of their earthly rules."

That is timely and wisely written, for this latest deviation of the South African Government strikes at the very root of the scientific society or professional association and their ability to serve the community. The idea of the Royal Society, the Royal Institute of Chemistry, the British Association, for example, divided into two or more bodies according to race, is as preposterous as it is absurd, and yet this is the natural effect of the policy of the South African Government. Well might *Minerva* add that the demands of Government are illegitimate where they would interfere with the discovery and communication of truth and would offer only the dubious benefits of uniformity of opinion. There the stand should be made and professional men and women should do what they can to remedy the situation through publicity and representation.

Minerva's unhesitating advocacy of this firm stand against the politics of national prestige and partisan advantage, the politics of demagogy and of ideology, where they infringe academic or professional auton-

---

[*] *Minerva*, a Review of Science, Learning and Policy, 1, No. 1 (Autumn, 1962). Edited by Prof. Edward Shils. Published under the auspices of the Committee on Science and Freedom. Pp. 1–144. Subscription-rate: 20*s*. or 5 dollars a year. Single issues, 5*s*. (London: C.S.F. Publications, Ltd., 185 Oxford Street, 1962.) [See also p. 1269 of this issue of *Nature*.]

omy or attempt interference with intellectual work with no acceptable justification is the more impressive in that it is fully recognized that restrictions on such autonomy may sometimes reasonably arise from the necessities of financial provision and public policy. It is reasonable, for example, for a Government to wish to have the culture of the people it rules studied systematically and to be made more accessible to intelligent appreciation. Again, it is reasonable for a Government to provide for the creation of more linguists and students of foreign cultures because it foresees a need for such qualifications, or to provide for the training of more engineers or chemists for a like reason. The legitimacy of such proposals or their value to purely intellectual development is not questioned, but it is none the less desirable that the principles on which the legitimacy of Government influence depends and the way in which that influence it exercised should be clarified through the secreting of experience. It is a healthy sign when the recommendations of a Scarbrough Commission or a Hayter Committee are not accepted without question or examination by those affected.

This latest intrusion of the South African Government's ideology into the work of professional bodies could be described as the pressure group in reverse. It is as clearly illegitimate as the demand that scientists or scholars be in agreement with the policies generally of any particular Government, and, failing that, be excluded or degraded, nor does it need this admirable article in *Minerva* to show librarians and other professional men and women, whether in South Africa or elsewhere, where their duty lies. Reports from Pretoria indicate that the Library Association there has already yielded to the Government's decree and that the Association was to discuss at a general meeting resolutions for the establishment of separate associations for different racial groups. Quite apart, however, from the damage done to professional bodies themselves, such steps put further difficulties in the development of scholarship and of professional standards among the peoples of Africa and hinder the emergence of the wise leadership that may well be the strongest hope of avoiding violence.

This latest decision of the South African Government is in fact as untoward from the point of view of the communication of ideas as it is from that of professional standards and competence. It is poles asunder from the vision that has inspired, for example, the recent establishment of the Thomson Foundation. Dr. Voerward and his colleagues seem determined to leave nothing undone which could engender bitterness and inflame the racialism which to-day is such a grave and growing threat to the future of Africa. There has been indication enough of lack of both wisdom and moderation in the proceedings at the General Assembly of the United Nations calling for sanctions against South Africa to give substance to Sir Hugh Foot's stern warning of the danger of conflict in general. This decision of the South African Government could well provoke moves to terminate South Africa's membership of such bodies as the Scientific Council for Africa South of the Sahara. Certainly scientific bodies and professional organizations will need to consider very carefully the implications of all official relations with the South African Government.

Beyond that, however, professional bodies generally have both the right and the duty to protest clearly and emphatically against the infringement of professional responsibility and efficiency which is represented by the South African Government's action. That action can no longer be represented as domestic; it impairs the structure of the republic of science itself. Nor is it less the duty of the professional body to protest in that such protest or representation may be ignored by the South African Government, for that it is made at all cannot fail to encourage their colleagues in South Africa. This, however, is only a first step. With it must go the most careful thought as to what other measures are possible. Here the overriding consideration should be that nothing is done which either offers further hindrances to the ease of communication and the development of full professional responsibility and competence, or which would of itself spread further the intolerance and intransigence which characterize the South African Government's policy, and thus endanger further the advance of science and learning and the conditions in which they flourish.

THE STRATEGY OF WAR

Studies of War

Nuclear and Conventional. By Prof. P. M. S. Blackett. Pp. viii + 242. (Edinburgh and London: Oliver and Boyd, Ltd., 1962.) 21*s*.

PROF. P. M. S. BLACKETT, who was awarded the U.S. Medal for Merit for teaching the Service Chiefs numerical thinking and so helping "to avoid running the war by gusts of emotion" has, in *Studies of War*, extended the methods of operational research analysis to the post-War politico-military situation. Never were emotions, excited by nuclear fears, so gusty and never, as he shows, was numerical thinking so perverted. His "Critique of Some Contemporary Defence Thinking" (Chapter 10) is relentless in its exposure of the numerical methods and the conclusions of some of the American analysts whose influence on nuclear strategy has been profound. He exposes "The Theory of Games" as the basis of conclusions which he demonstrates as false.

He anatomizes the arguments which, posing as numerical, hardened out as the "Great Deterrent", "Massive Retaliation", "Graduated Deterrents", "Limited Nuclear War", "The Balance of Terror", etc. He shows how sums were made to add up to suit inter-Service rivalries, and how the theorists ignored the real facts of situations.

In Chapter 11 he says: "A military commander, planning a campaign or battle, attempts, as a matter of course, to envisage the situation as it must appear to his opponent. He must first find out all he can about the material facts of his opponents' military deployment, and, secondly, he has to assess the possible intentions of his opponent for its use. This has been described as guessing what goes on on the opposite side of the hill".

The lessons of Blackett's book have been amply demonstrated in the course of the Cuban crisis when the world was brought to the precipice edge of nuclear decision by the direct confrontation of the United States and the U.S.S.R. The material facts were conspicuously, indeed suspiciously, plain in Cuba—so plain to aerial cameras that Chairman Kruschev might just as well have sent President Kennedy the ground-plans. They showed the clearing of the area, the arrival of the missiles (without the war-heads), the pouring of the concrete for the launching pads, and all the preparations of a vulnerable site, ninety miles from the American coast. No one asked: "How long does concrete take to set?" Because of urgency, the President of the United States took the war-like initiative of declaring a naval blockade, to intercept the war-heads. This action assumed that the threat of attack was so imminent that it left no time to go to the Security Council nor, in the event of a Soviet veto, to the U.N. General Assembly—a matter of, at most, days since both were in session in New York. What was the real time-factor in terms of the hardening of the launching pads? Here was a case where the intentions—on both sides—were political as much as military—a consideration which Prof. Blackett emphasizes throughout the whole of his book.

Apart from his studies of military strategy, Prof. Blackett has included "Tizard and the Science of War" and studies of science and Government. His Part 2 spells out the methods and scope of operational research. As a collection of articles and lectures they have the merit of not having been edited by hindsight. He reproduces them in the order of their first publication to show how he modified and corrected his own thinking.

RITCHIE CALDER

THREE GREAT SCIENTISTS: MANSON, WILLIAM HERSCHEL AND LYELL

Patrick Manson

The Father of Tropical Medicine. By Sir Philip Manson-Bahr. (British Men of Science.) Pp. viii + 192 + 22 plates and 9 figures. 15*s*.

William Herschell

By Dr. Angus Armitage. (British Men of Science.) Pp. xii + 158 + 14 figures. 15*s*.

Charles Lyell

By Sir Edward Bailey. (British Men of Science.) Pp. x + 214 + 24 plates + 20 figures. 15*s*.
(London and New York: Thomas Nelson and Sons, Ltd., 1962.)

IDEALLY there are not two cultures but only one. With the passing of the years since the Renaissance, parts of the great corpus of human knowledge have developed more than others. The growing and expanding stem of knowledge has bifurcated before it has ramified. The problem of an attempt at re-integrating, which so occupies teachers in schools, writers and broadcasters, and is not unknown in some universities, is clearly of fundamental importance in any system worthy of the name of education. An improvement in the scope and method of teaching the history of science will do something to show the scientist the cultural and human background of his endeavours, and the student of the humanities the changes in the thought, behaviour and potentialities of human beings which have been wrought by science and its applications.

This new series of monographs of *British Men of Science* is to be welcomed. Three have appeared, and sixteen more are planned for the future: nearly a score of great names altogether, most of them have been strangely neglected in adequate books in the past. Thus, it is pleasing to think that soon we may expect a work on each of Joseph Black, William Gilbert, John Herschel, William Thomson Kelvin, among others whose lives are better known, even to the layman. The publishers are to be congratulated in having been able to secure authors so well qualified to deal with each subject. The three volumes which have now appeared augur well for the remainder of the series. The production of the books with regard to paper, printing, binding and illustrations is excellent, particularly in view of the low price. They should have a wide vogue. Among other uses, they will prove valuable in background reading for sixth-form science and arts students, elementary texts for university students reading science and its history, and excellent introductions to the history and methods of science for the intelligent adult wishing to understand his world in terms of the progress of science.

Patrick Manson has been called the 'father of tropical medicine' and his son-in-law, Sir Philip Manson-Bahr, presents the personality and work of this great man in the light of his close association with him over a period of thirteen years. A former work by the same author, in association with the late Colonel A. Alcock, on the same subject is more heavily scientific. Here the treatment is simpler and popular in the proper sense of the word. The book shows how Manson set out to investigate the many terrible, mutilating and weakening diseases of the tropics, and how he evolved a new and original conception of the nature of insect-borne diseases. This was to be one of the chief factors in the development of the understanding, treatment and prevention of such diseases and was to lead to the opening up of the tropics to European settlement and to a vast improvement in the health of the native inhabitants. The author describes conditions as they were when Manson started his work, assesses his contribution to the study of tropical medicine and to its establishment as an essential department of medical science, and details progress up to the present.

Although there is a considerable literature on William Herschel, Dr. Angus Armitage has performed a useful task in presenting the astronomer in the context of his time, his discoveries and the development of astronomy on the foundations of his work. The story of the professional German musician, turned into the self-taught astronomer, who rose from obscurity to world-fame almost literally in a night, is worth telling again. (His extraordinary achievements as a musician in England and Germany are often overlooked. Recently, Lady Susi Jeans, the widow of another distinguished astronomer and cosmologist, played a concerto for organ and string orchestra by the same Herschel.)

Herschel opened up a new era in astronomical optics: he invented an improved telescope, hundreds of which he made and sold. By means of this new telescope Herschel was able to look farther into space than anyone before him, and he thus opened up a wide field of speculation as to the construction of the heavens. The astronomical and physical phenomena, problems and procedures with which Herschel was concerned are described, his researches and discoveries are examined and his contributions to astronomy are assessed and placed in their historical context.

Sir Edward Bailey's splendid little book on Charles Lyell is very readable and is doubly welcome because historians of science have unjustifiably tended to neglect the great geologists. Among other things the book is a good and even exciting travel story. Sir Edward shows with great clarity and some delightful light touches how Lyell gained a wide and varied personal knowledge of the features of the landscape of Britain, Europe and North America, and was thus able "to originate just and comprehensive views concerning the structure of this globe". Lyell's chief work, the *Principles of Geology*, practically vanquished all those geologists who believe that changes in the Earth's surface had been brought about by tremendous catastrophes involving the wholesale destruction of the landscape.

The general editor of the series of monographs is Sir Gavin de Beer.

W. L. SUMNER

IN HONOUR OF SPINOZA

Creation, Emanation and Salvation

A Spinozistic Study. By Prof. H. F. Hallett. Pp. xi + 234. (The Hague: Martinus Nijhoff, 1962.) 25 guilders.

Spinoza, Dreihundert Jahre Ewigkeit

Spinoza-Festschrift, 1632–1932. Herausgegeben von Siegfried Hessing. 2 vermehrte auflage. Pp. xliii + 205. (Den Haag: Martinus Nijhoff, 1962.) 25 guilders.

IT might be incorrect to describe these two scholarly books as in praise of Benedictus de (or Baruch) Spinoza (1632–77), but they are assuredly in his honour. The authors accomplish their tasks as leading authorities in this field of philosophy, and that means presenting their readers with an assessment of Spinoza's genius in the light of twentieth-century criticism and historical method. To the possible query whether we have not enough commentaries already in this particular branch of learning, the writers might well reply that one can never delve too deeply into the great themes of human experience—life, morals, death—and more especially in an age wherein a materialistic outlook is widespread. Furthermore, it is worth more than mere formal recollection that Spinoza, alone perhaps with Plotinus, achieved a purity of the concept of truth unequalled in their day, and probably never exceeded in any subsequent period. Scientists reading these two volumes, or for that matter either of them, may care to be reminded that Spinoza's doctrine of truth finds due applications in parts of morphology, which is nowhere better displayed than in the writings of the late Dr. Agnes Arber. To have her observations by one's side in reading the pages of these recent publications is to add pleasure to pleasure.

Prof. H. F. Hallett's work, *Creation, Emanation and Salvation*, is, he tells us, a Spinozistic study, as indeed was his earlier *Aeternitatis*. After two sections of prolegomena come Part 1, "Nature", and Part 2, "Morality", followed by three indexes: (i) References to the works of Spinoza; (ii) Personal names; (iii) Subjects and catchwords. In view of certain contemporary and plausible attempts to limit (in some cases severely) the objectivity of empirical data, the remark that "man is not an extrinsic spectator of nature" is of supreme moment. This is indeed the human predicament, from which it follows that metaphysics has the paramount aim of making sure that error does not creep in as a result of this vital involvement. One can infer from this that our ratiocination must be clothed with humility, if only to avoid the gross mistake of imagining that research can stand, as it were, on the touchline, and watch with bland unconcern what is going on even in the very plane of discourse which the intellect is striving to comprehend. Or, in the manner of the Psalmist, there is for us no *super flumina*; it is always *de profundis*, whether we like it or not.

The present approach to the central problem is activistic, and this in its turn conditions the author's speculations, both ethical and political. It is well known that Spinoza used the geometrical method; yet it was not essentially by means of it that he produced a truth-doctrine akin to the German *Wahrheit*, or at least one that would support a degree of veracity beyond that which the natural scientist can reach in any purely experimental environment. For Spinoza demands an idea which is, in effect, self-certifying.

Prof. Hallett, in discussing morality and salvation, touches on the relationship between man and his tools, or materials; in fact, his position as a craftsman. Thus, technique is a kind of morality. Everybody who deals with substances knows that to do violence to his clay is no part of a sympathetic, let alone an accomplished, potter. Here, our author is almost in the tradition of John Ruskin: the point is made with a delicate touch which is wholly convincing. A portrait of Spinoza on scraper-board by the author provides an appropriate frontispiece.

Spinoza: Dreihundert Jahre Ewigkeit is in the nature of a dedicatory collection of essays in memory of the period 1632–1932. As one would expect, the emphasis is on the aspect of eternity. The present edition, with the help of additional distinguished authors, has emerged triumphant from the trials and frustrations of the original version of 1933. One can only marvel that from the Germany of that year anything of cultural value should have survived. In itself, it is an example of the indestructibility of truth, and how significant it is that its focal point should have been Spinoza.

The series starts with a salute by the editor; the other members cover most facets of this remarkable life. As an example, there are five scenes, depicted by Franz Droop. These are: (i) a room in Spinoza's house at Amsterdam; (ii) in a near-by street; (iii) in a tavern; (iv) in the Synagogue, on July 27, 1656, the day of his 'excommunication"; (v) in his study at The Hague, the year of his death. These are typical conversation-pieces, redolent of seventeenth-century Holland. Other essays deal with Spinoza's political theory, his biblical criticism, the basic dualism of his system, and so forth. The book ends with three short "remarks" by Einstein, Freud and Wassermann, all testifying to the qualities of mind which make Spinoza stand out as a philosopher for all time. His three-fold structure of knowledge—*intuitiva, ratio, imaginatio*—is secure as one of the treasures of the human race.

F. I. G. RAWLINS

DARWIN VINDICATED

The Structure and Distribution of Coral Reefs

By Charles Darwin. Originally published 1842. Pp. xii + 214 + 3 plates. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1962.) 1.95 dollars; 17*s*. net.

It is now more than one hundred years since Darwin published his work on the structure and distribution of coral reefs and it is good to have this classic readily available in a well-printed paper-back.

A very welcome foreword is contributed by Prof. H. W. Menard, who remarks: "It may be unprecedented for an essentially correct hypothesis to be the centre of a raging controversy for more than a hundred years". He goes on to discuss the hypothesis of the origin of atolls by subsidence in the light of more recent work. The Royal Society's attempt to test this theory by drilling on Funafuti Atoll had been inconclusive, but more recent results at Eniwetok Atoll and elsewhere by drilling, supplemented by seismic soundings, have demonstrated that subsidence has predominated for thousands of years. It has been shown, for example, from seismic studies of four atolls that each has a cap of coral several thousand feet thick, and so Darwin's hypothesis may be taken as proved.

Prof. Menard adds: "Sprinkled among the atolls of the Western Pacific are about a hundred and fifty 'guyots' or ancient islands now submerged to depths as great as a mile. They were originally identified as former islands solely because they are truncated volcanic cones and the truncation could only be ascribed to erosion at sea level. This deduction has been amply confirmed by deep-sea dredging of guyots. The tops are covered with rounded cobbles and fossils typical of very shallow water. . . . Former islands in favourable locations have been capped by coral that has grown upward as fast as they subsided, and these are atolls. Other former islands, lacking the coral, are now guyots".

With Darwin vindicated, the controversy has now shifted to the much-debated question of the cause of the subsidence.

W. J. Rees

STAINING TECHNIQUES

Staining Animal Tissues

Practical and Theoretical. By Edward Gurr, with a foreword by Sir Howard W. Florey. Pp. xii + 631 + 1 photograph. (London: Leonard Hill (Books), Ltd., 1962.) 84*s*.

In recent years a number of books devoted to collections of staining techniques has been published, so that one might question the need at the present time for yet another such volume. The author of this work, however, has stated in his preface that he has attempted to bring together a number of such techniques and staining procedures which were previously scattered throughout many books and journals, so this present book does in fact form a welcome addition to the laboratory bookshelves. It is undoubtedly a great convenience to have such compilations readily at hand.

At the same time, Mr. Gurr has devoted some ninety pages to a discussion of various aspects of the mechanism and theory of staining reactions. Such observations are essential to a proper understanding of the rationale of microtechnique, but one must question the advisability of treating them in a practical text. Of necessity this section must be subordinate to the main part of the book, devoted to the actual techniques themselves, and this leads to a rather limited treatment. For myself, I would like to see such theoretical aspects dealt with at greater length in a separate publication.

The selection of techniques given is very wide (more than 300 staining procedures and 700 recipes are included) and designed to meet the needs of workers in widely separated fields. Each method is given in detail, and notes of special points are appended.

An appendix giving details of the preparation and use of various fixatives, embedding methods and mountants is a useful addition to the main part of the book. There is, one is pleased to note, a very adequate bibliography and a comprehensive author index and general subject index. The book is well produced, indeed, almost too well produced, as its price is rather high and this may well prevent its acquisition by some laboratories. It is welcomed as a valuable source of reference for the busy histologist.

SISAL HEMP

Sisal

Twenty-five Years' Sisal Research. By G. W. Lock. (Tropical Science Series.) Pp. xvii + 355 + 62 plates. (London: Longmans, Green and Co., Ltd., 1962.) 60*s*.

Sisal, like so many tropical crops, has reached its greatest stature far from home. This hard fibre, which owes its name to the Mexican port of Sisal whence came the early shipments, is now a major product first of East Africa, with Tanganyika by far the greatest producer, and secondly, of Brazil.

East Africa's lead, not only in bulk of shipments, but also in scientific production, owes much to the far-sighted establishment in 1934 of a research station for sisal in Tanganyika. G. W. Lock was placed in charge, and his direction of the work over a period of twenty-five years has enabled him to write with exceptional experience of the crop.

An introductory chapter outlines the history of sisal in East Africa, going back to seventy years ago, when an article in the *Kew Bulletin* inspired the German agronomist Hindorf to give the plant a trial in Tanganyika where he was employed. The second chapter contains a useful account of the botany and life of the plant. From then on, the author is concerned with the practical handling of the crop, its propagation and raising in the nursery, its establishment in the field, its maintenance, nutrition, and pest-control, its cropping and processing to make fibre. Throughout, the author's recommendations, whether as to choice of planting material or to spacing in the field, are backed by the results of field experiments covering most aspects of cultivation. While forming, therefore, a very adequate manual of the growing and preparation of sisal, the work shows in interesting manner how agricultural research can serve and can shape efficient production.

The author writes clearly and competently, providing a good index and ample references to relevant literature. The book is well produced, with admirable illustrations, and is a welcome addition to the series of works on tropical crop-plants.

T. A. Russell

The Fishes

By Dr. Url Lanham. Pp. 116+24 plates (New York and London: Columbia University Press, 1962.) 5 dollars; 40*s.*

At a lower price this book could fill an empty niche by providing an introduction to fishes, written in the broadest detail, specifically for those without any biological training and not wanting to dig deeply into the subject. The style is simple and lucid, but one cavils at such unnecessary 'simplifications' as "Jaws were invented by one or more stocks of the jawless fish . . .", and "Fishes that evolved the first crude airfloats were, . . . , able to redesign the fins, . . ."

Dr. Lanham touches on most aspects of ichthyology. There is a chapter each on the origin of fishes, on the evolution of the Agnatha, sharks, Dipnoi and bony-fishes, while many facets of anatomy, physiology and ecology are dealt with in five chapters. The two chapters on marine and freshwater fishes are, in effect, summaries of zoogeographical and distributional problems. Speciation is touched on in a chapter devoted to trout and other salmonids. Since all these subjects are covered in one hundred and nine elegantly printed pages, it will be realized that the scope of the book is limited. Nevertheless, it does admirably serve to introduce its subject and even give satisfactory answers to many of the questions asked by the general reader.

The underlying thesis of the book is an unusual one for a popular work, namely the importance of the swimbladder in determining major evolutionary steps and later anatomical and morphological trends within the vertebrates grouped as fishes. Many more advanced text-books have passed too lightly over this fundamental dichotomy in the history of the fishes. It is thus very regrettable that the section dealing with living lungfishes is so misleading, partly by the inclusion of factual errors and partly by loosely phrased statements which result in unsupportable implications.

One final complaint: there is no bibliography.

P. H. Greenwood

The Biology of Malayan Scolytidae and Platypodidae

By F. G. Browne. (Malayan Forest Records, No. 22.) Pp. xi+255+9 plates. (Kuala Lumpur: Government Press, 1961.) 15 Malayan dollars.

This valuable contribution to tropical entomology is the work of a forest officer who spent some thirty years in Malaya and Sarawak. When Mr. Browne began his observations on the bark and ambrosia beetles, less than 10 per cent of the 435 species mentioned in this book were known to occur in Malaya and nearly 250 of them were completely unknown to science.

Part 1 occupies 56 pages and it includes an essential chapter of the habitat and the fauna and another on the general biology of the Scolytidae and Platypodidae. This second chapter explains, with numerous examples, the food and feeding habits, the social organization, the relationship with hosts, the enemies and the economic importance of these bark and ambrosia beetles, as well as the evolution of their general habits. It is very well written and will appeal to any student or worker in forest entomology.

Parts 2 and 3 are devoted to the bionomics of the Malayan species of the Scolytidae and Platypodidae respectively. The descriptions are detailed, well set out and supported by references. There are, of course, some gaps in the information, but with this book now available they should be easier to fill.

The appendixes contain not only a bibliography and an index to the beetles but also a summary of the species of actual or potential importance and an index to the host plants. The plates and line drawings are very good and add appreciably to the usefulness of this *Malayan Forest Record.*

Those who have been aware for many years of Mr. Browne's work in Malaya and Sarawak are very glad that he has recorded in book form his observations and the help he has received from other entomologists on these two families of beetles which are so important to the forester in the tropics. Mr. Browne has now turned his attention to West Africa, where he is in charge of the West African Timber Borer Research Unit.

C. J. Taylor

A Conspectus of Aphids as Vectors of Plant Viruses

By J. S. Kennedy, M. F. Day and V. F. Eastop. Pp. iii+114. (London: Commonwealth Institute of Entomology, 1962.) 25*s.*

Workers in the field of plant virus transmission will welcome the publication of an index of aphid-transmitted viruses and their vectors. This work is a compilation from the literature up to the end of 1960 and consists mainly of two alphabetical indexes. The first lists under each host plant all the recognized viruses that have been tested for transmissibility by aphids. The second is a reciprocal index of all the aphids which have been tested for virus transmission and includes not only the records of successful transmission but also the failures to secure transmission: these latter include many previously unpublished records. There is a bibliography of some 450 titles.

While recognizing that there are obvious gaps in our knowledge and possibly inherent biases in the kinds of information available, the authors have analysed the material they have collected in an attempt to test various hypotheses concerning virus–vector relationships. This work undoubtedly points the way for future investigations and in systematizing this large body of information the authors have produced a work which will be an invaluable reference.

Bruce Johnson

The Classical Theory of Fields

By L. D. Landau and E. M. Lifshitz. Translated from the Russian by Morton Hamermesh. (Course of Theoretical Physics. Vol. 2). Pp. ix+404. (London, Oxford, Paris and Frankfurt: Pergamon Press, 1962 revised second edition.) 80*s.*

This is the second English edition of the book originally published in 1948 in the U.S.S.R. The present edition is substantially the same as that of the earlier English edition published in 1951, although there has been some re-arrangement of the subject-matter. The principal change is the addition of a chapter on cosmological problems which is somewhat uncritical and unselective in its approach. Quite properly there is a reference to the solutions of the gravitational equations at first found by Friedmann in 1922, but the names of de Sitter and Lemaitre do not appear.

A number of additional exercises has also been added in the present volume, which gives a very readable introduction to the special and general theories of relativity and to electromagnetic theory and the theory of light.

G. Temple

EXPERIMENTS ON THE PROBLEM OF CONTROLLED THERMONUCLEAR REACTIONS*

By R. S. PEASE

U.K. Atomic Energy Authority, Culham Laboratory, Abingdon, Berks.

THE object of our research is to devise a practical method of releasing the nuclear energy of light elements in a controlled fashion for generation of power. The only method at present under extensive investigation aims at releasing this energy by using thermonuclear reactions in a deuterium and tritium gas at temperatures in the range 5×10^7 °K – 5×10^8 °K. To achieve a net output of energy, the gas must be confined adiabatically for times exceeding τ, where τ is given by the Lawson criterion[1]:

$$n\tau \geqslant 10^{14} \text{ cm}^{-3} \text{ sec.}$$

Here n is the number of nuclei per c.c. in the gas. The rate of energy release, which is proportional to n^2, has to be in a practicable range; and so n is envisaged as being in the range 10^{13}–10^{17} cm^{-3}, with corresponding minimum confinement times of between 10 and 10^{-3} sec. At these densities and temperature, the gas is fully ionized, the laws of motion of the ions and electrons are predominantly classical, and the forces on the particles are predominantly collective. Such a gas is often called 'plasma', following Langmuir's terminology.

The plasma is to be confined with magnetic fields, so that all envisaged thermonuclear reactors consist essentially of a volume of plasma isolated from the surrounding walls of a containing vessel by a region containing only magnetic fields. The confining forces arise from electric currents j flowing in the plasma which interact with the magnetic field B, so that in equilibrium the familiar Ampere law of force becomes: as

$$\boldsymbol{j} \wedge \boldsymbol{B} + \textbf{grad}\, P = 0$$

where P is the plasma pressure. On integration, this equation shows that, in simple geometrical situations, the magnetic pressure $B^2/8\pi$ outside the plasma must balance the plasma pressure P plus the pressure of any magnetic field inside the plasma. The current density j (and the corresponding pressure gradient) decays with time due to electron–ion collisions, unless it is continually regenerated from an external source; but the collision-rates (and the corresponding plasma resistivity) decrease as the temperature increases; and even without an active maintenance of the current, the characteristic decay time due to binary collisions can easily be made long enough to satisfy the Lawson criterion.

However, the total situation inside the containing vessel is not one of thermodynamic equilibrium, and the potential energy of the system may well be able to relax by other mechanisms, and thus destroy the confinement in too short a time. Such other mechanisms are usually referred to as instabilities, and involve the collective motion of the gas. Instability can also occur during the generation and heating of the plasma.

The nature and growth-time of instabilities and their effects on plasma confinement is the crucial point of uncertainty in all present-day envisaged thermonuclear reactors. The collective forces in a plasma depend on the velocities and positions of all the particles in the system; it is thus impossible to calculate them rigorously. Indeed, the theoreticians have to adopt drastic simplifications to make any headway at all. Consequently, we have to proceed as in other fields of research, by making approximations in the calculations and by doing experiments both to check the approximations and to suggest new ones.

This framework to our research remains as it was when last discussed at the British Association in 1958. There are now many laboratories working in this field, and some hundreds of papers are published every year. I shall limit my report mainly to work at Harwell, where our progress has been broadly indicative of the advance of the subject as a whole. (This work has now been transferred to the Culham Laboratory of the U.K. Atomic Energy Authority.)

Experiments on *Zeta*

Experiments on *Zeta* have been carried out to obtain a picture of the main phenomena occurring in a magnetic confinement system[2], and particularly over the past two or three years to get quantitative measurements of the confinement properties[3].

It will be recalled that the plasma in *Zeta* is confined by the self-magnetic field B_θ of a pulsed high-current toroidal discharge. The currents also generate and heat the plasma. There is a d.-c. longitudinal magnetic field B_z generated by solenoidal windings on the torus, called a stabilizing field, because its purpose is to eliminate the ordinary electrodynamic instabilities of a flexible current-carrying conductor. The discharge lasts for about 3 msec, and the initial gas is usually deuterium at a pressure of between 0·1 and 10 m torr.

The discharge should behave in the following way if the plasma were a well-behaved resistive medium. Because of the well-known skin effect, the current should initially flow largely on the surface of the plasma, and then diffuse throughout the plasma during a time of about σR^2, when σ is the plasma conductivity and R the plasma radius. The same skin-effect should also trap the stabilizing B_z field within the plasma. In the initial stages of the discharge, the field configuration should thus look like Fig. 1*a*. After the time σR^2, which is estimated to be between 100 μsec and 1 msec, depending on exact conditions, the configuration should have degenerated to the configuration of Fig. 1*b* with the fields B_θ and B_z intermixed. The details of the degeneration process are complicated by the variation of plasma conductivity with temperature. The important relations are that the conductivity σ is proportional to (temperature)$^{3/2}$; and the temperature should increase as the power fed in j^2/σ and as the initial gas pressure decreases. The degeneration is closely analogous to the above-mentioned resistive decay of a confinement system; but in *Zeta* the total pinch current is sus-

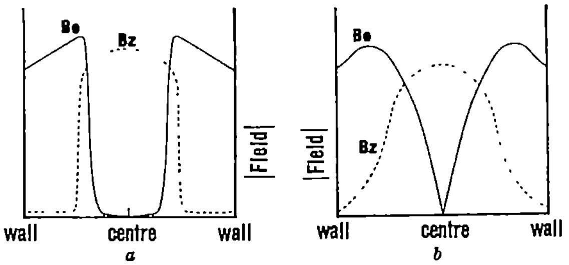

Fig. 1. *Zeta* configuration; magnetic field distributions across the tube bore
a, During initial transient phase; *b*, after diffusion of the skin current

tained by the applied electric field, and the mixed field system of Fig. 1*b* should also confine plasma. However, the sustained currents feed energy into the plasma by ohmic dissipation; and unless this energy is radiated, which should not occur in pure hydrogen plasma at the currents used, the plasma pressure will eventually exceed the confining magnetic pressure and confinement will cease. The confinement time of the mixed-field configuration is thus limited to a value which comes out to be also about σR^2.

Observations have been made on both phases of the *Zeta* discharge. Early observations on the transient configuration at the beginning of the discharge, both by inductance measurements and by search coils, suggested that at the low gas pressures then used, there is virtually no skin effect at all. This matter has been further examined in a detailed series of search coil and Langmuir probe observations by Lees and Rusbridge[4]. They have found a skin effect, and have measured the duration time. They have obtained the conductivity σ from classical binary collision theory using measured values of the electron temperature. Their results on the observed and calculated values of the 'skin-duration time' (defined in an arbitrary but explicit manner) are shown in Fig. 2. The three important results are:

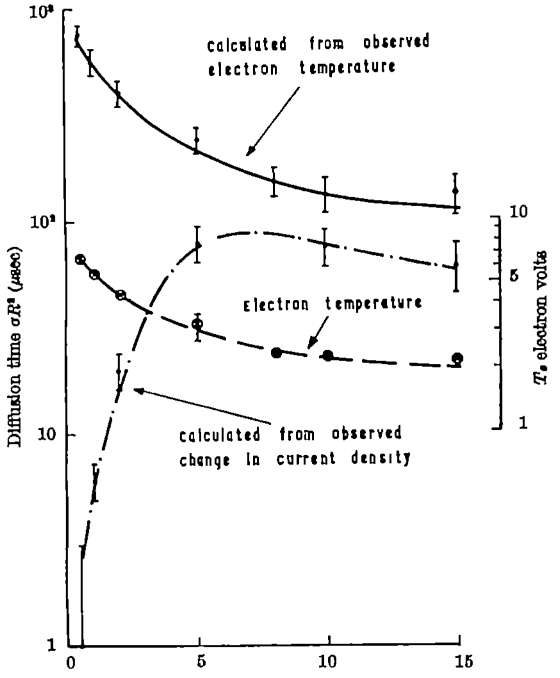

Fig. 2. Duration of the skin effect in *Zeta* from measurements of magnetic search coils compared with the theoretical time σR^2, as a function of initial gas pressure. (By permission of D. J. Lees)

(1) There is adequate agreement between experiment and theory at high initial gas pressures and low plasma temperature (about 2 eV), with a marked skin effect the presence of which is confirmed by inductance measurements.

(2) At lower initial pressures, the electron temperature is higher (as expected) and reaches values of about 10 eV, and the conductivity is calculated to improve; but the skin duration time is observed to decrease instead of increasing—a result which is in qualitative disagreement with the expectations already outlined.

(3) In the final limit of low pressure, the skin disappears about one hundred times faster than it should by ordinary resistive diffusion.

We thus have a clear example of a configuration decaying by some process other than that of binary collisions between the electrons and the ions.

Let us now turn to the steady-state phase after the skin currents have diffused. First, we must distinguish between conditions where the plasma is radiation cooled and where it is not. Observations[7] show that at high pressures or in strongly radiating gases such as argon, the discharge is largely radiation cooled, but at low pressures in hydrogen and deuterium the radiation can be neglected. In these low-pressure conditions, the plasma ought to get hot and we expect a confinement time of at least 500 μsec which increases with the electron temperature, again depending on the detailed conditions assumed.

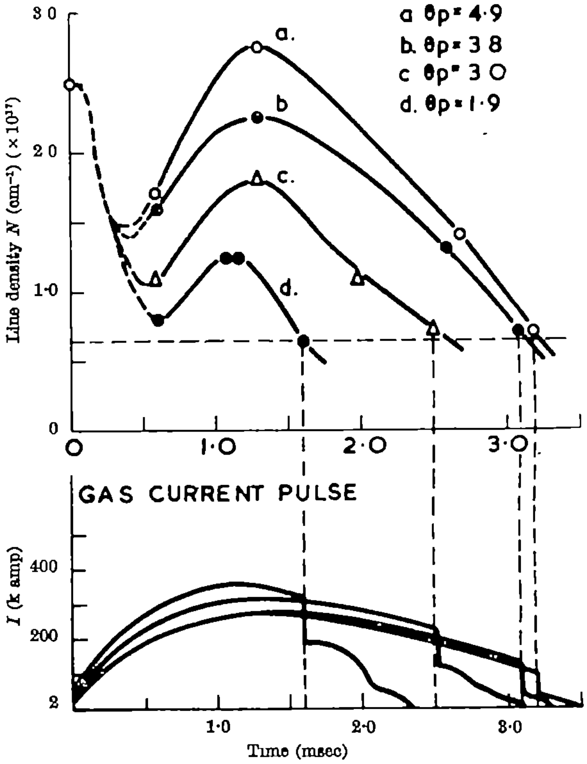

Fig. 3. Gas content (atoms per unit length) of the *Zeta* discharge, as a function of time, deduced from ultra-violet line radiation. The current wave-forms of the discharges concerned are shown in the lower part of the diagram. The parameter θ_p is the ratio of B_θ at maximum current to the initial stabilizing B_z. (From Burton, W. M., and Wilson, R., *Proceedings of the Physical Society*, 78, Pt 6, by permission of the authors and the Institute of Physics and the Physical Society)

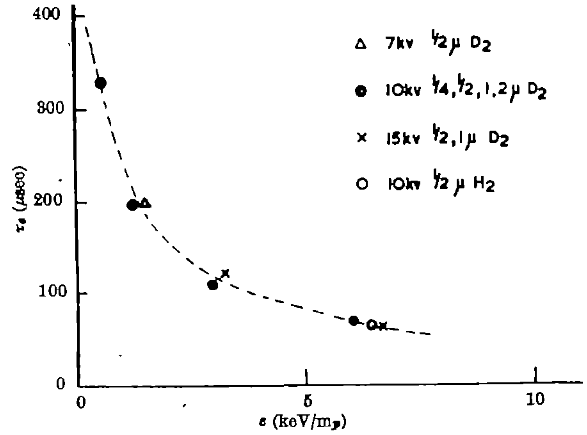

Fig. 4. Plasma confinement time τ_e in *Zeta* as a function of energy supplied per unit mass of initial gas (ϵ = keV per proton mass), for various discharge conditions (from Burton and Wilson (ref. 5))

The actual confinement time has been measured by extensive analysis of the duration of ultra-violet spectral line emission from added trace elements[5]. Emission from highly ionized states, such as argon VIII, should last essentially as long as the tracer element is present in the plasma. A short duration of such emission is in fact observed and shows that the trace element is escaping. All trace elements give the same result—a confinement time typically about 100 μsec. Light from the low states of ionization or from neutral gas should only last a very short time, because these species are ionized rapidly. In this case, however, a relatively long duration of light emission is observed which shows that fresh gas is injected during the discharge. We believe that it is dislodged from the inner surface of the metal torus.

These measurements have been made fully quantitative, and give a plot of the amount of plasma in the discharge as a function of time (Fig. 3). We see that towards the end of the pulse the net loss of plasma reaches a point at which there is a spectacular drop in the discharge current of about 100 k amp in 2–5 μsec. Plausible theory suggests that at this point the discharge begins to behave rather like an accelerator. Strong beams of electrons accelerated to about 10 keV are observed in the gas; they appear to interact violently, and they dissipate the energy of the magnetic configuration by striking the walls of the torus.

These results on the plasma loss and injection have been checked by another novel technique, the intensity of infra-red continuum radiation. For this work, very sensitive and rapid detectors have been developed at the Royal Radar Establishment, Great Malvern, together with the spectroscopes. They enable us to measure plasma density during the pulse without using added tracer elements or probes. The plasma density observations[6] fully confirm the ultra-violet analysis of loss and injection of plasma shown in Fig. 3.

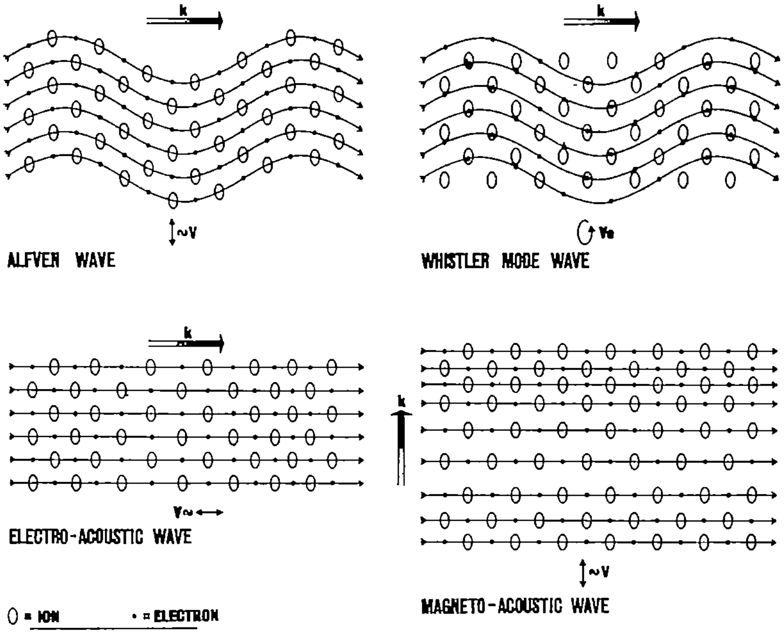

Fig. 5. Some simplified wave motions possible in a magnetized plasma
a, Alfvén waves; *b*, Whistler mode waves; *c*, electro-acoustic waves parallel to the magnetic field; *d*, magneto-acoustic waves perpendicular to the field

Measurements of fluctuating electric and magnetic fields in the plasma[7], and precise quantitative analysis of the Doppler widths of vacuum ultra-violet line spectra[8], strongly suggest that the plasma gets to the walls in a coarse random walk process, each step of which consists of the plasma moving about 10 cm at 10^6 cm/sec. It takes 10 steps to get to the walls—and hence takes about 100 μsec to lose the plasma—in rough quantitative agreement with the ultra-violet and infra-red measurements.

The loss of plasma at low initial gas pressures is thus fully documented. It is at least five times more rapid than one would expect. Moreover, the confinement time, just like the skin diffusion time, should increase with increasing energy per particle (temperature). In fact, measurements show that the opposite occurs (Fig. 4); and only by using dense plasmas that are relatively cold, can we approach confinement times that agree with the σR^2 times of ~ 500 μsec. It is possible that in radiation-cooled conditions, plasma confinement time is longer, but fluctuations of the magnetic fields are still observed and indicate instabilities.

The anomalously rapid skin diffusion and plasma loss can be interpreted as an anomalously low plasma conductivity σ, which appears as the temperature is raised. Indeed, the corresponding 'excess resistance' of the discharge has been directly observed and examined[3]. However, all these anomalous effects are observed to depend on the mass of plasma involved (in particular they increase as the plasma mass is decreased); these excess resistance effects are therefore believed to be simply a reflexion of the observed collective motions of the plasma, rather as the excess resistance of a dynamo (back E.M.F.) is a reflexion of the motion of the armature and not of the resistivity of the windings.

Thus it is clear that in *Zeta*, confinement is being destroyed by instabilities, and that so far we can only obtain high temperatures at the cost of poor

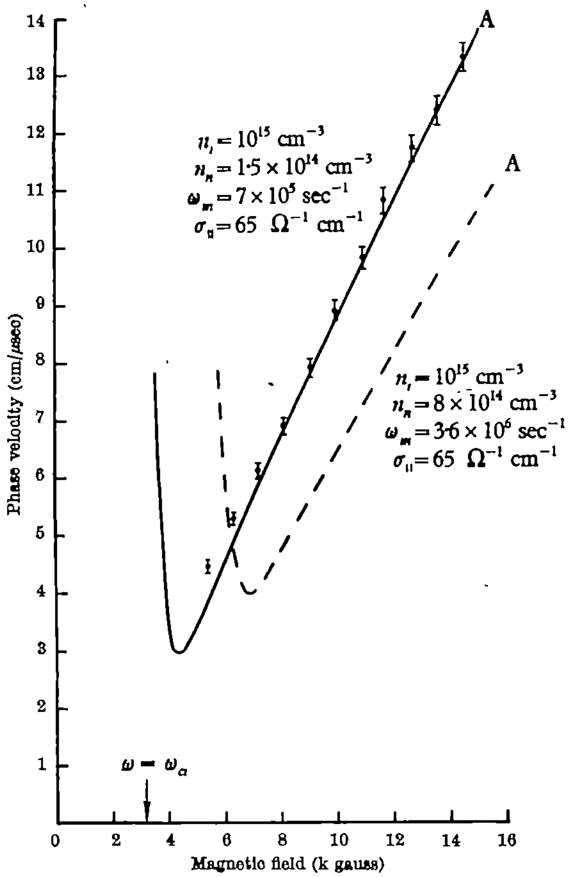

Fig. 6. Phase velocity of Alfvén waves in an argon plasma at fixed frequency as a function of magnetic field. n_i, ion density; n_n, neutral density, ω_{in}, ion-neutral collision frequency; σ = plasma conductivity; – – –, theoretical curves. (From Jephcott, D., and Stocker, P. M., *J. Fluid Mechanics*, 13, Pt. 4. by permission of the authors and the Cambridge University Press)

confinement. The origin of the instabilities is not entirely clear, and I shall describe instead parallel experiments on other apparatus.

Collective Motion of the Plasma

First, we have started controlled experiments on plasma motion for small disturbances. In this case, it is natural to use Fourier analysis, so that the motion can be described as waves. When a plasma system is in thermodynamic equilibrium, all these modes correspond to ordinary oscillatory waves which are damped. When it is not in thermodynamic equilibrium, which is the situation we are trying to achieve, some of the modes may turn out to be exponentially growing disturbances or to be growing waves, driven by the potential energy of the system: that is, the modes are unstable. The basic equations are the same whether the mode is stable or unstable. The experiments aim to show whether or not these equations are really applicable in a plasma by measuring the properties of plasma waves.

A plasma in a magnetic field can, according to theory, propagate many different varieties of waves. Four of these are illustrated in Fig. 5. The Alfvén waves, predicted theoretically in 1944, are transverse displacements of the plasma and magnetic field together, which propagate along the lines of force with a phase velocity of $B/\sqrt{4\pi\rho}$, where ρ is the plasma mass density. These waves are low-frequency waves, because when the frequency exceeds the ion cyclotron frequency the ions no longer move with the lines of force. A second wave mode shown, corresponds to the higher frequency case, when the electrons are stuck to the lines of force, but the ions are not. This is the 'whistler' mode of propagation, predicted by the Appleton–Hartree dispersion relation, and studied in connexion with whistler radio atmospherics. This is the only mode for which much observational data was available in 1958[9]. This mode propagates along the lines of force at frequencies between the electron- and ion-cyclotron frequencies. The other two modes correspond roughly to sound waves along and across the lines of force.

Fig. 6 shows the measured phase velocity of Alfvén waves in a cylindrical argon plasma, obtained by Jephcott[10], as a function of the magnetic field strength. The main predicted features of these waves—phase velocity proportional to magnetic field, and no waves at frequencies higher than the ion cyclotron frequency—are found experimentally. The observed phase velocity and also the damping length agree with precise theory to within 20–30 per cent. The main uncertainty of the experimental measurements is the amount of neutral gas in the plasma, and when this single parameter is adjusted, the observations both of phase velocity and of damping are within a few per cent of theory over a wide range of magnetic field strengths. Similar agreements have been obtained with whistler mode waves by Dellis[11], with longitudinal sound waves by Little[12] and with transverse (magnetic) waves by Niblett *et al.*[13], using 'thetatron' devices at Aldermaston.

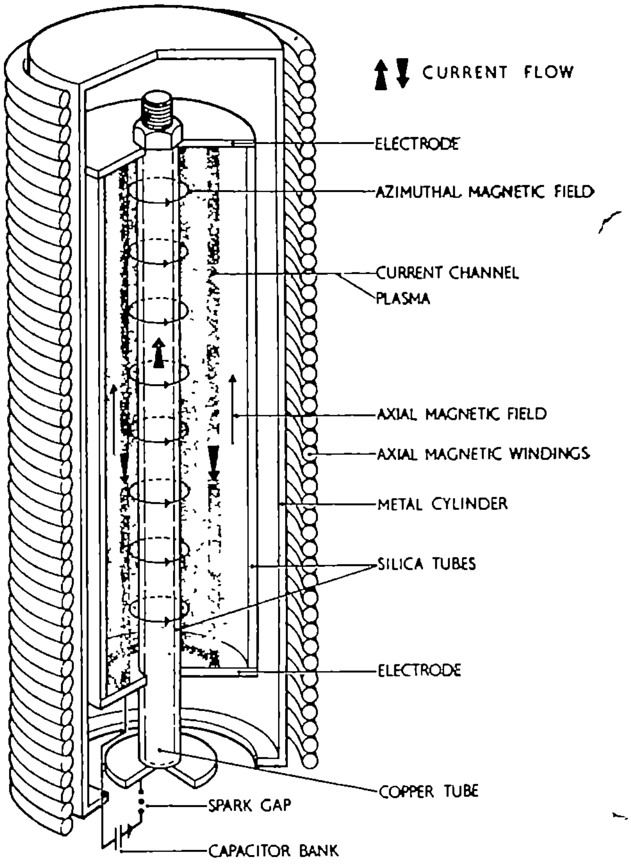

Fig. 7. The hardcore experiment

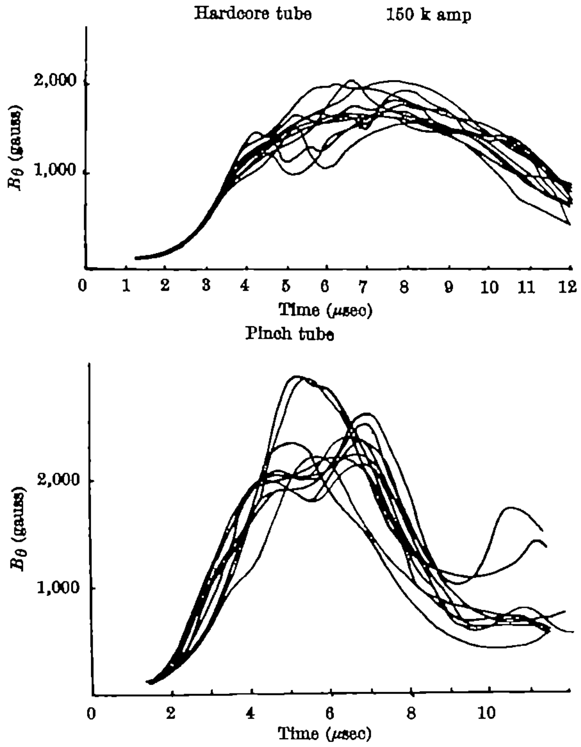

Fig. 8. Overlay of search coil measurements of magnetic field strength, in hardcore and pinch geometries. The search coil was at a radius of 8·5 cm. (By permission of K. Aitken and P. Reynolds)

As a result of these experimental studies, together with similar ones elsewhere, we can have more confidence in the basic equations used to describe the collective motion of plasma. In the case of *Zeta*, the theoretical equation for a straight cylindrical analogue predicts unstable hydromagnetic modes, corresponding roughly to a combination of magnetic sound waves and Alfvén waves, in a rather narrow band of wavelength. Sound waves could also be excited by the relative drift motion of the electrons and ions due to the currents in the plasma, provided the gas pressure is fairly low. The disturbances in *Zeta* have low frequencies, less than the ion cyclotron frequency, and this qualitative result fits the present theoretical predictions.

Stability Studies in the Hard-core Configuration

A second line of experimentation is to investigate more specialized confinement configurations which are predicted to be stable in those modes which might give trouble in the ordinary pinch. This line has been pursued at Harwell by Dr. R. J. Bickerton[14] and his colleagues using a modification of the pinch configuration called 'hard core' (sometimes called 'unpinch') geometry. As shown in Fig. 7, the plasma is confined between a B_θ field generated by a central current carrying rod (the 'hardcore') and an external B_z. It is predicted to be stable by the same theory—infinite-conductivity hydromagnetic theory—which predicts instabilities in *Zeta*.

The observations have been made on straight tubes with discharge currents of up to about 200 k amp, lasting for about 15 μsec. The same discharge tubes have also been operated in the stabilized pinch geometry so that direct comparison can be made. The principal observations have been made with magnetic search coils, which have shown in the first place that the configuration achieved is of the type expected. The important observation made at Harwell and also in the United States and France is that, in the hardcore geometry, there are fluctuations of the magnetic search-coil signals indicative of instabilities (Fig. 8). Indeed, the magnitude of the fluctuations approaches that seen in the pinch in comparable conditions. They correspond to movements of the plasma of about a centimetre or so in a tube of 15 cm radius. The frequencies of the fluctuations correspond to those of hydromagnetic waves. Discharge tubes of varying length have been used to gauge the end-effects inevitably associated with straight tubes—the effects seem to be negligible—and search coils external to the plasma are used to avoid the disturbing effect of the probe in the plasma. It thus seems that simple infinite-conductivity hydromagnetic theory is insufficient to predict stability. The gas pressures in these experiments has been kept high so that drift-excited sound waves should not occur. The penalty has been a relatively cold (5 eV), rather resistive and not fully ionized plasma.

At present it seems quite possible that the finite conductivity of the plasma produces growing Alfvén waves. Normal mode calculations on a rather simplified model using finite instead of infinite conductivity shows that such growing waves should occur in a resistive medium[15], and experiments[16] using mercury colums in place of plasma show that indeed they do. However, some of the detailed predictions of this particular model do not fit with observed properties of the fluctuations, and it seems quite possible that other proposed modes of instability resulting from finite conductivity[17] may be the predominant ones.

Confinement in the Cusp Geometry

A third line of experimentation on magnetic confinement has been carried out by Dr. T. K. Allen *et al.*, using cusp geometry (Fig. 9). We started experiments in this geometry because its stability properties are believed to be radically different from those of the pinch[18]. In cusp geometry, the magnetic field surrounding the plasma everywhere increases as one moves away from the plasma towards the walls. Thus, a plasma protuberance at the surface encounters a stronger magnetic pressure than in the unperturbed state, and this stronger pressure provides a powerful restoring force regardless of the shape or magnitude of the protuberance. This contrasts with the stabilized pinch geometry, where the field decreases outwards from the plasma, and the stability depends on

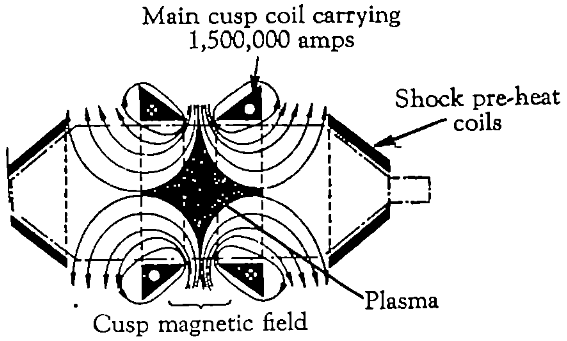

Fig. 9. Cusp geometry experiment

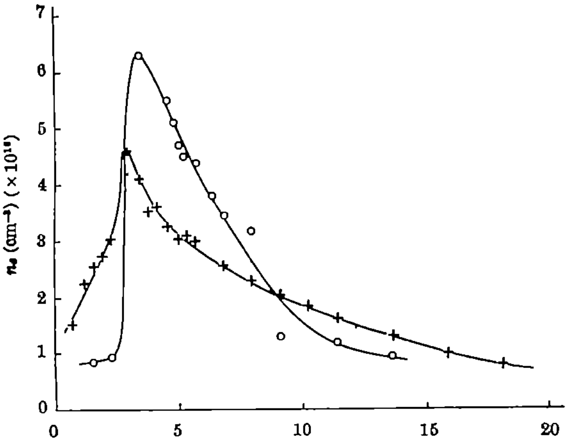

Fig. 10. Spectroscopic measurements of plasma density as a function of time in cusp geometry experiment

shear in the magnetic field. However, the simple cusp as used by Dr. Allen is not a complete containment system, because the lines of force are not closed within the vessel, and plasma can leak along the lines of force out along the axis of the system, and also out of the ring leak between the coils.

In these experiments[19], an initial plasma with $n \sim 10^{15}$ cm^{-3} and a temperature of 5×10^4 °K is produced by colliding shock waves. This plasma is then trapped and compressed by the cusp magnetic fields which rise to about 50,000 gauss near the coils in about 10 μsec. High-speed photographs of the plasma have shown that this system appears to be working approximately as planned, although during the compression phase instabilities sometimes appear due to the rapid inward acceleration of the plasma[20]. The final plasma obtained occupies about 100 c.c., has a particle density of about 5×10^{16} cm^{-3} and probably reaches temperatures of about 2×10^5 °K.

The density has been measured from the absolute intensity of the continuum radiation, and also from Stark widths of spectral lines (Fig. 10). After an initial increase during the compression phase the density is found to decrease with time so that most of the plasma escapes in 10–20 μsec. By using small thermocouples and piezo-electric crystal probes, the energy and the momentum of the escaping plasma has been measured in different regions near the wall (Fig. 11). These show that the plasma loss occurs along the lines of force and is limited to a narrow region at the cusp apices where the lines of force penetrate the tube walls. Both the width of the leak region (a few milimetres) and the rate of loss of plasma appear to be roughly in accord with relatively simple considerations of the flow of gas through an orifice the width of which is determined by simple collisional diffusion across the lines of force.

Because of the leaks in this cusp geometry system, the plasma confinement time (~10 μsec) is rather short, and the plasma is not very hot (⩽20 eV). So far as they go, the results suggest that the plasma confinement in this system is behaving according to plan, and does not appear to suffer from the instabilities of the type observed in the pinch system. This experiment is one of the few that gives observational colour to the hope that stable confinement can be achieved.

Discussion

These experiments represent some of the more important ones carried out at Harwell since 1958 on controlled thermonuclear reactions. They have demonstrated the importance of collective motion of the plasma in leading to the breakdown of magnetic confinement systems and provide us with some evidence on the nature of the plasma motion. For this work, novel techniques have been introduced, and we can now make quantitative measurements over a large part of the vacuum ultra-violet spectrum and of the far infra-red spectrum which will greatly help future experiments. Confinement of plasma in accordance with the binary collision processes required to be the major dissipative factor in envisaged thermonuclear reactors has been achieved only with low temperature and rather resistive plasmas, and no good evidence has been obtained either by us or by others that plasma at thermonuclear temperatures can be stably confined.

In specially designed experiments, the observations of small-scale collective motion are in good quantitative agreement with the linearized wave theory of plasmas. This gives us confidence that at least some of the drastic simplifications used in theoretical studies are meaningful. Using such simplifications, confinement systems which avoid some of the instabilities predicted for *Zeta* can be envisaged, including pinch systems with very thin current skins and specially arranged stabilizing fields. However, the results of experiments in the hardcore geometry suggest that infinite conductivity hydromagnetic theory is insufficient to predict stability. The initial experiments in cusp geometry seem to suggest that systems in which the magnetic field increases away from the plasma boundary may turn out to be more

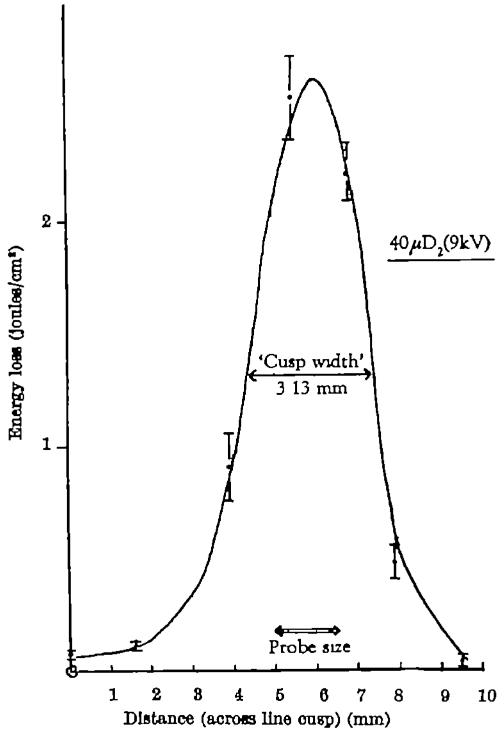

Fig. 11. Energy loss in the cusp geometry trap measured by small thermocouples placed near the ring cusp apex; mean of 10 shots. (By permission of Spalding, I. J., to be published)

promising for stability, a view which has substantial theoretical argument to support it.

It will, however, be clear that our present knowledge of the extreme complexities encountered in our work on magnetic confinement systems does not permit me to make any firm prediction about the ultimate achievement of a working controlled thermonuclear reactor based on the magnetic confinement principle.

VOICEPRINT IDENTIFICATION

By L. G. KERSTA

Bell Telephone Laboratories, Inc., Murray Hill, New Jersey

VOICEPRINT identification is a method by which people can be identified from a spectrographic examination of their voice. Closely analogous to fingerprint identification, which uses the unique features found in people's fingerprints, voiceprint identification uses the unique features found in their utterances. Fingerprinting uses the inked impressions of the ten fingers; voiceprinting uses the spectrographic impressions of the utterances of ten words frequently used in telephone conversations. Thus, when the source material is contextual, the voiceprints for specific cue words are extracted and compared with previously recorded voiceprints of the same cue words.

Fig. 1 illustrates two types of voiceprints of the word 'you' uttered by the same male voice. The voiceprint shown on the left is a conventional bar spectrogram, showing time proceeding from left to right and frequency increasing from bottom to top. The amplitude, or loudness, is indicated by the density of

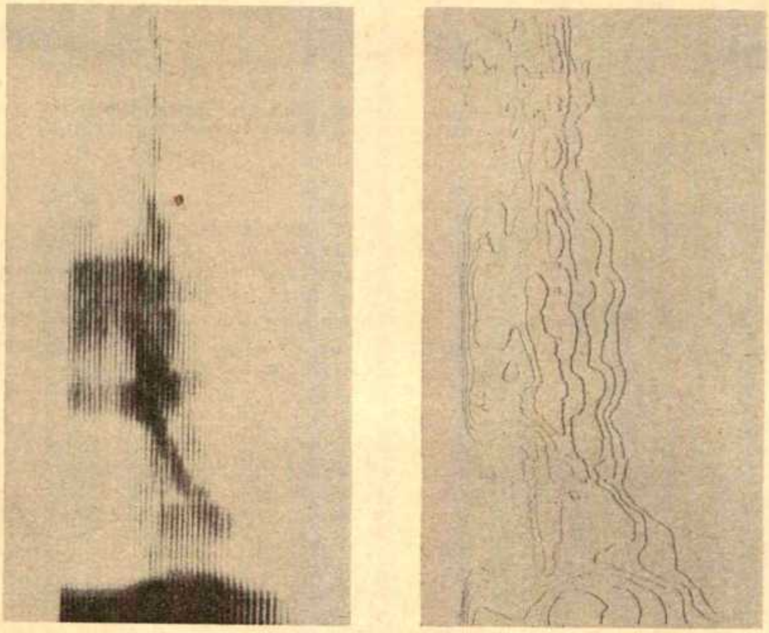

Fig. 1. Male voice uttering 'you'. Bar voiceprint on the left; contour voiceprint on the right

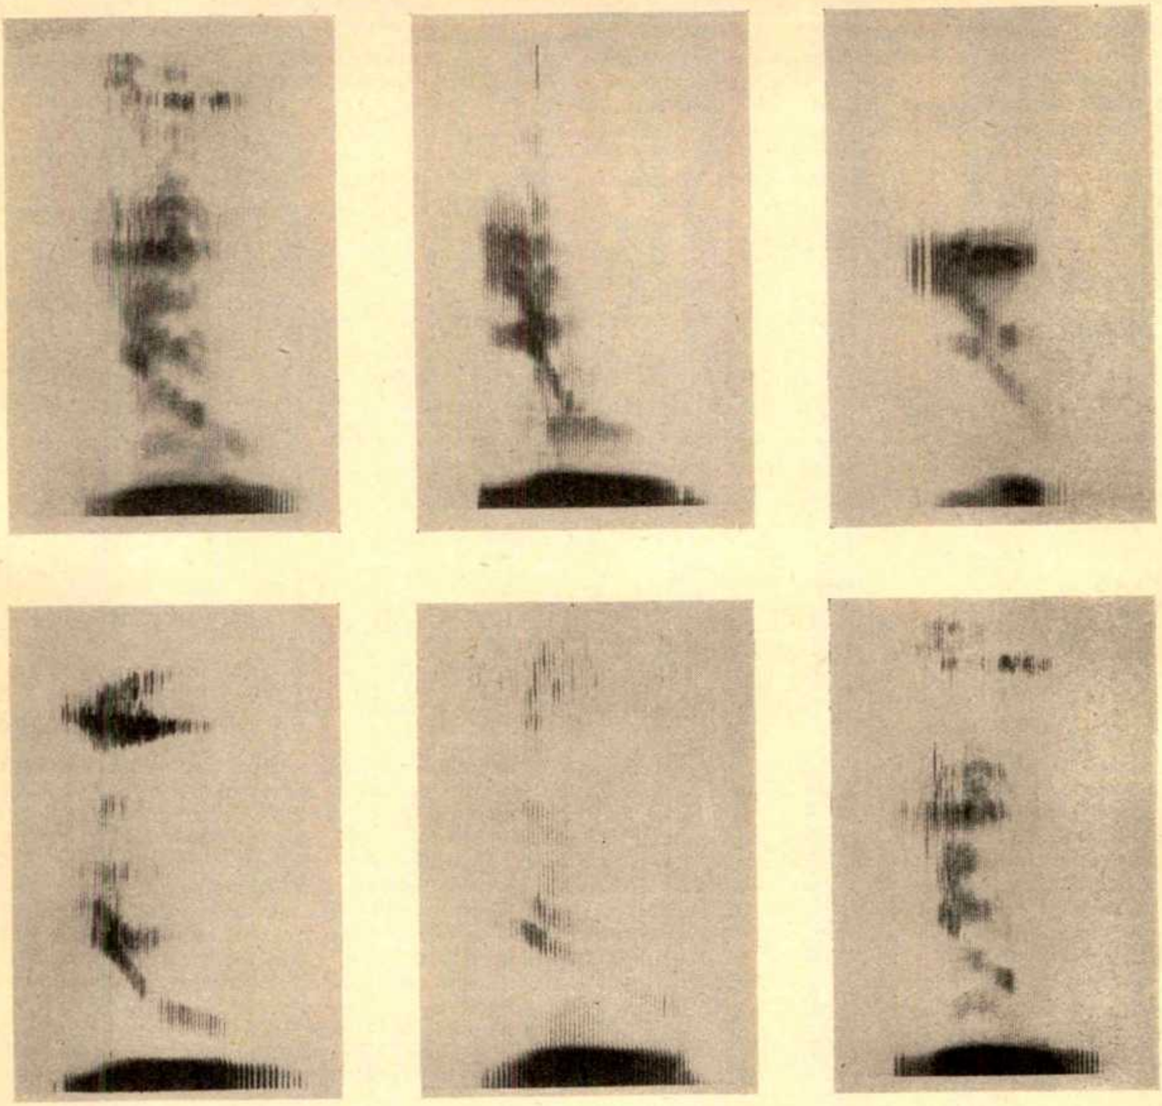

Fig. 2. Bar voiceprints of five male speakers uttering 'you'. One of the speakers uttered 'you' twice. Upper left and lower right were spoken by the same person

the marking. The range of loudness detectable this way is only a little better than 2 to 1 because of the limits imposed by the spectrogram paper characteristics. The contour spectrogram (voiceprint) shown on the right has the same time and frequency dimensions as the bar spectrogram. The amplitude, however, is shown by seven quantized or contour steps. The term 'contour' seemed applicable because the amplitude contours on this type voiceprint are like the altitude contours on a topographical map. With contour portrayals, amplitude doubles with each inward progression from one contour to the next, and we arrive at amplitude peaks as one arrives at altitude peaks on a topographical map.

Subjective experiments were conducted to learn how well subjects could match voiceprints when presented in random matrices, and secondly, how well individual unknown prints could be identified with the correct speaker in a population of previously uttered and filed prints. These results will be presented and discussed later in this article.

Fig. 2 shows a sample array of bar voiceprints of the word 'you'. There are six utterances by five male speakers. Can you detect the two bar prints which were uttered by the same persons ? Similarly, Fig. 3 shows contour voiceprints of the word 'you' uttered by the same speakers, but the order has been changed. Can you detect the two contour prints uttered by the same person ?

You probably had no difficulty in selecting the matching prints, so let us now explore the speech mechanism and see why each person's voice is unique. Fig. 4 illustrates the human vocal mechanism. The parts which principally determine voiceprint uniqueness are the vocal cavities and the articulators. The vocal cavities are resonators which, much like organ pipes, cause energy to be reinforced in specific spectrum areas, dependent on their sizes. The major cavities affecting speech are the throat, nasal and two oral cavities formed in the mouth by the setting of the tongue. The contribution of the vocal cavities to voice uniqueness lies in their size and the manner in

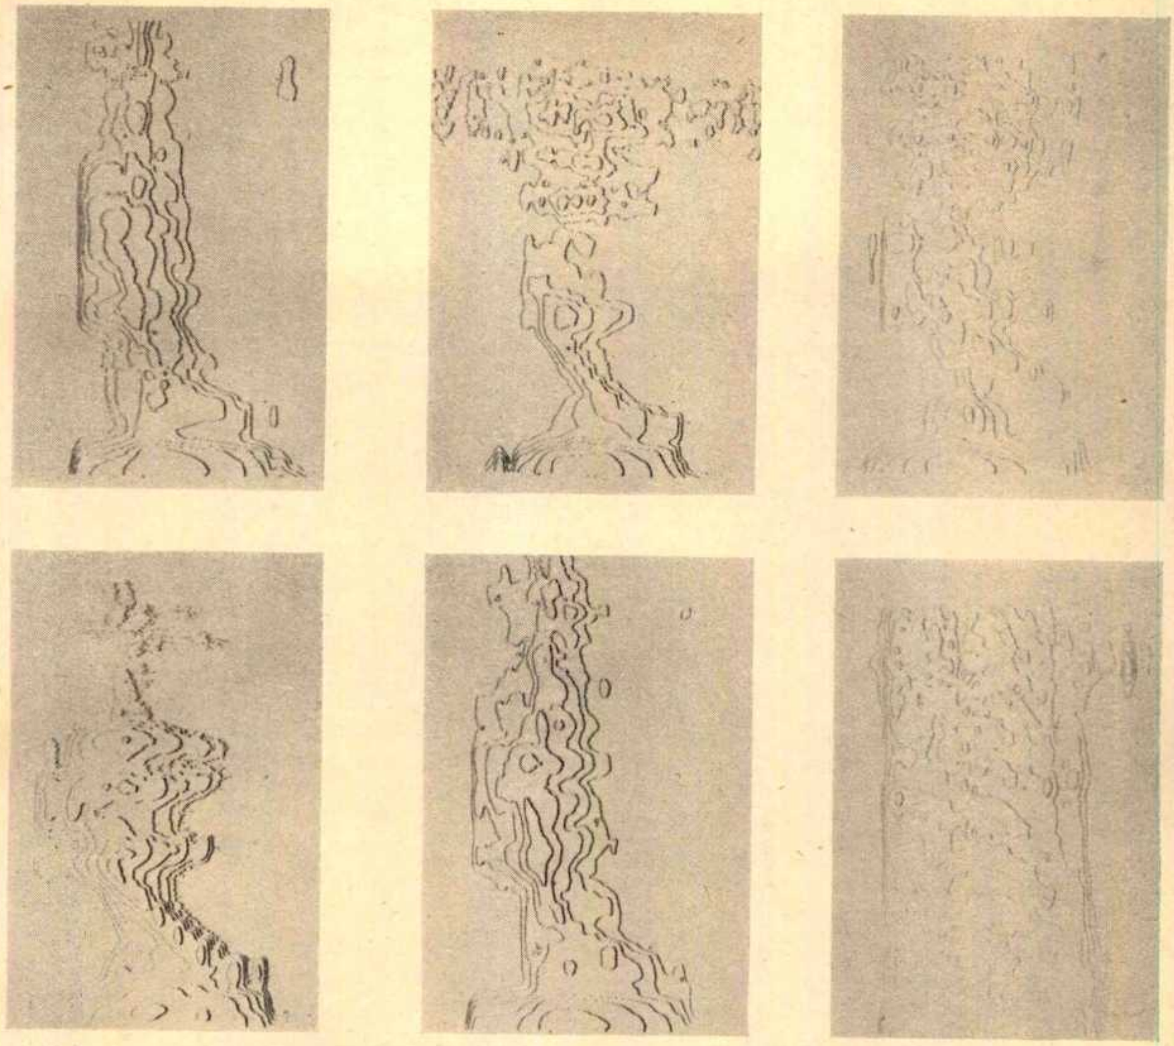

Fig. 3. Contour voiceprints of five male speakers uttering 'you'. One of the speakers uttered 'you' twice. Upper left and lower middle were spoken by the same person

which they are coupled. The likelihood of two people having all vocal cavities the same size and coupled identically seems remote. A still greater factor in determining voice uniqueness is the manner in which the articulators are manipulated during speech. The articulators include the lips, teeth, tongue, soft palate, and jaw muscles, the controlled dynamic interplay of which results in intelligible speech. We well know that intelligible speech is not spontaneously acquired by infants. It is a studied process of the imitation of those around him who are successfully communicating. The desire to communicate causes the infant to accomplish intelligible speech by successive steps of trial and error. Success requires that he learn a dynamic complex manipulation of interrelated muscles controlling the movement of several articulators. Again, the chance that two individuals would have the same dynamic use-patterns for their articulators would be remote. My claim to voice pattern uniqueness then rests on the improbability that two speakers would have vocal cavity dimensions and articulator use-patterns identical enough to confound voiceprint identification methods. Final proof of identification uniqueness depends on a sufficiently large population sample to support the present claims. Recently, when fingerprint identification experts were asked if fingerprinting afforded unique and infallible identification, they replied: "We do not surely know, because we have information for only 93 million people so far".

Let us now consider the identification successes for several subjective experiments. The subjects used in these identification experiments were female high school students 16–17 years old. They were each given about one week of training in voiceprint reading and detection of unique clues in voiceprints. In all, eight girls were used for various periods during the past year. They worked in panels of two because it was found that success scores were markedly better when two panellists were able to consult each other about their identification selections.

Data from an experiment in voiceprint matching are shown in Fig. 5. The voiceprints used here were four different discrete utterances by 5, 9 and 12 male speakers. The words used were 10 frequently used words in English conversation, namely: *the, to, and, me, on, is, you, I, it,* and *a*. The subjects were given a random matrix of voiceprints for the 5, 9 or 12

'talker' groups. Each matrix included four different utterances for each word used. The resultant random matrices included 20, 36 and 48 voiceprints respectively. The experiments were conducted for both bar and contour type voiceprints. As can be seen the lumped errors for all cue words ranged from 0·35 to 1·0 per cent for bar prints, and from 0·37 to 1·5 per cent for contour prints. The number of data for each point is shown in the legend and in all cases was more than 800. Errors recorded for individual words ranged from 1·8 per cent for the word *to* to no errors for the word *a*.

Data in Fig. 6 illustrates the success of voiceprint matching when the cue words were extracted from contextual material. These results show that the lumped error for all cue words is approximately 1·0 per cent. It will be remembered that comparable data (Fig. 5) for discretely spoken words showed a lumped error of 0·8 per cent. The error for these results as shown (Fig. 6) range from 2·0 per cent for the word *is* to no errors for the word *you*.

In the following experiments an identification game was played. It was presumed that one had on file a number of voiceprints identified with a group of people. It was further presumed that there were some unidentified voiceprints for some of the same population. The object of the game was to identify the unknown prints with one of the group of file prints. The file population with which the unknown had to be identified varied between 9 and 15. The results of one such experiment are shown in Fig. 7. These data indicate that in 2,000 identification attempts, the lumped error of misidentifications when using all cue words was 1·0 per cent. I would like to make it clear that the errors shown are for identifications made with single cue words. This is analogous to attempting fingerprint identification with the print of only one finger. In practice, a voiceprint identification would generally be made using several cue words. The identification error in such a case would be the product of the errors for each word. The resultant percentage error would, of course, be very small. It will be noted that the cue words are shown on the abscissa and the error index for each word on the ordinate. The range is from 3·0 per cent for the word *is* to no errors recorded for words *I*, *on* and *it*.

As one may suspect, some voices are more difficult to identify than others. Fortunately, no voices used so far can be classed as difficult to identify. Results in Fig. 8 show the subjective errors committed in identifying a group of 11 male talkers. The identification errors range from 2·4 per cent for two talkers to no errors for three talkers. Each datum point indicated contains at least 163 identification attempts.

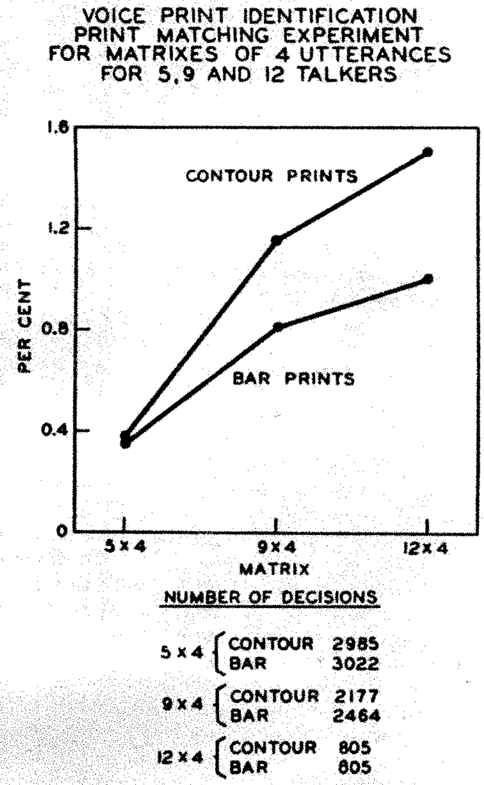

Fig. 5. Lumped data errors for voiceprint matching experiments with random matrices

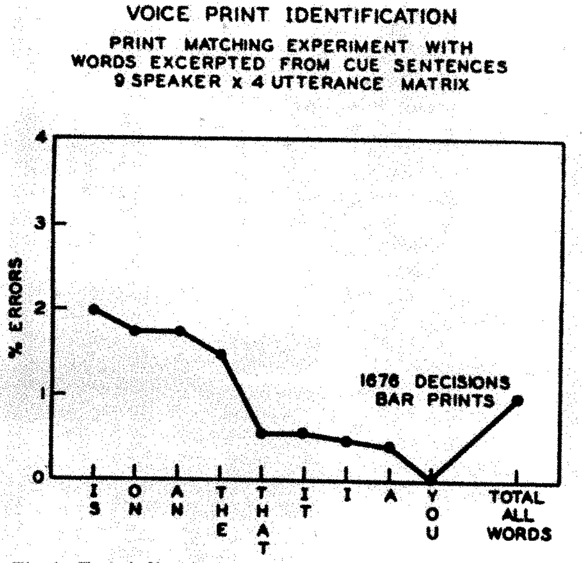

Fig. 6. Error indices for cue words in print matching experiment

The talkers, incidentally, were chosen as normal male voices with no marked dialectal influences.

Experiments similar to those described previously were also conducted for female voices. There was no evidence of complicating difficulties and the data are comparable with those shown for male voices.

A sampling of data has been presented here which was limited in scope because of space restrictions for this article. Other experimental data encourage me to believe that unique identifications from voiceprints can be made.

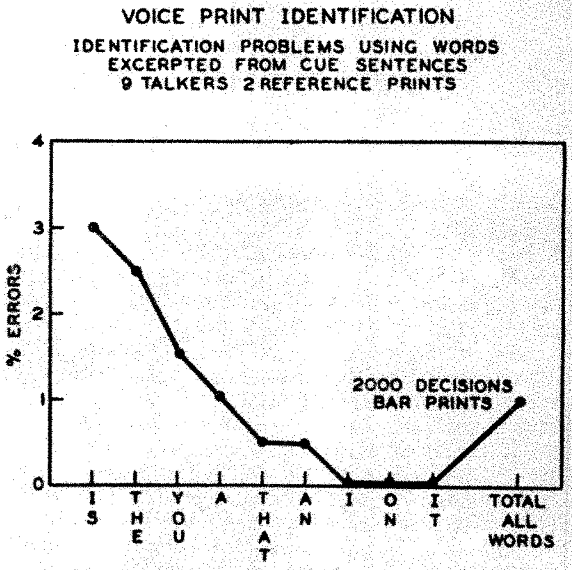

Fig. 7. Identification problem errors for each cue word

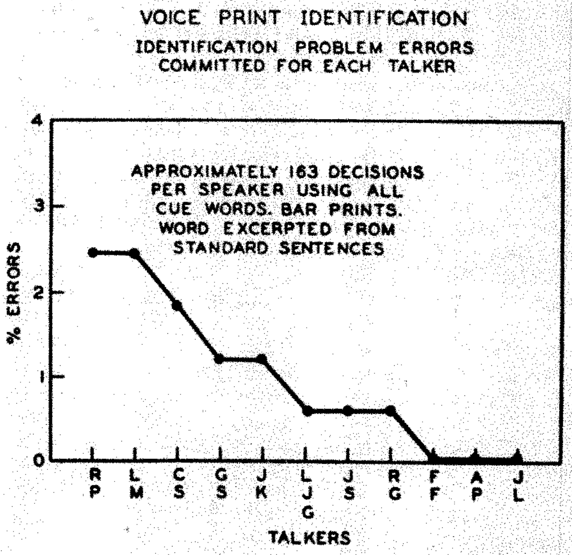

Fig. 8. Identification errors committed for each talker

Work continues, there being questions to answer and problems to solve. Among these are: (1) Is the voice unique enough to afford infallible identifications? This requires sampling the voices of a much larger section of the population. (2) Does the voice of an adult change significantly with time? If so, how? (3) How will attempts to disguise the voice succeed? (4) How successful in disguise are voice mimics? All these questions must be answered by substantiating experimental evidence. It is my opinion, however, that identifiable uniqueness does exist in each voice, and that masking, disguising, or distorting the voice will not defeat identification if the speech is intelligible.

Work is in progress to devise a classification and indexing system for filing voiceprints. The system must afford compactness, rapid access, and reduce the population of filed prints needed for subjective identification to a relatively small number. Several ideas for automation are being examined and seem to hold promise in meeting the foregoing requirements.

BEHAVIOUR OF MONKEYS TOWARDS MIRROR-IMAGES

By PROF. K. R. L. HALL

Department of Psychology, University of Bristol

MIRRORS have been used in field studies of birds to elicit various behaviour-patterns, and it has also long been known that anthropoid apes take a great interest in the perception of their mirror-images. Thus Yerkes and Yerkes[1] described how "in any captive chimpanzee, but especially in an isolated and, therefore, lonesome individual, the self-image commands attention and arouses interest which leads to varied investigative expressions. In a word, the novel object is treated as if it were a fellow being. It may be touched repeatedly with fingers, hands, feet, lips, cheeks, or poked, slapped and struck gently or vigorously with hands, feet or both. Also there may be sudden reaches behind the mirror, if such is used as source of image, in seeming endeavour to surprise the other animal and grasp it. Social interest for a time waxes, as such behaviour runs its course; then it wanes, and presently the image is neglected" (p. 253).

Systematic observational or experimental studies of the behaviour of captive monkeys and apes towards their mirror-images or reflexions or to other mirrored objects or animals are, however, lacking. The present investigation arose as a result of preliminary observations of so-called 'imitation' and 'social facilitation' in four patas monkeys, *Erythrocebus patas*. These monkeys had all been recently captured in Northern Nigeria, and were obtained through the Wellcome Research Laboratories at Beckenham. Until they came to our own laboratories, they had not taken part in any kind of experimental situation. It is reasonable to assume that, in the wild, these animals would not see anything comparable to the mirror-image other than the reflexion of themselves on the horizontal plane such as is provided by stream or pond water. Hence, the initial, and subsequent, behaviour of such experimentally unsophisticated animals to mirrors or mirror-like situations seemed to be worthy of investigation.

Of the four monkeys used in the work, two were full-grown adults, one male and one female, and two were juveniles, also one male and one female. The exact age of none of them was ascertainable. They were normally kept in separate living cages, and, according to the experimental situation, were not allowed to see or have contact with each other. The two young ones were kept in one room, and were let out on most days to be together in a large cage which was divisible into two compartments according to the requirements of the social facilititation and imitation studies. The two adults were in a separate room adjacent to this, and they were also occasionally allowed out into the room. During the latter part of the observations, all four cages were put in the same room while alterations to the other rooms were being made, but appropriate screening of the cages was carried out when experimentally necessary.

Prior to any experimental observations being made, it was noted that whenever the two young monkeys were released into their living room, they showed intense and active interest in the images of themselves that they could see in the glass parts of the partitions dividing, on two walls, their room from the adjacent two rooms. The behaviour seen consisted of a variety of 'observing responses', such as standing on hind-legs, crouching low to the ground with head held low and staring, and of cautious approach towards the partition. In addition, the young female, in particular, frequently made 'gaping' or 'yawning' responses in which, while staring towards the reflexion, she lowered the head while opening the mouth to fullest extent, then raised the head again to the normal horizontal position. This reaction would occur with the animal in the sitting, normal standing, or low-crouched postures, and in partial form (for example, opening wide of the mouth without lowering of the head) as well as in the complete form described. The significance of this reaction, its variation in form and in circumstances of occurrence, and its relations to other behaviour components of the species' repertoire have yet to be fully worked out, so that the term 'yawning', to be used hereafter, is simply a usefully descriptive one. A similar reaction has been described in wild chacma baboon males by Hall[2], and in captive rhesus monkeys by Hinde and Rowell[3]. The interest to the two young animals of these reflexions in the glass partitions delayed any kind of social responses between the two often for several minutes after release from the cages.

The adult male's responses in the same kind of situation were even more prominent, the 'yawning' being often a reaction in which the head was lowered, when the animal was standing, almost to the ground. The adult female, on the contrary, tended to show cautious investigatory and observing responses and rarely, if ever, 'yawned'. This female had been a cage-mate of the adult male for some weeks prior to coming to our laboratories. The adult male has shown a similar, but much briefer, kind of response on seeing his image in a pane of frosted glass standing upright against a wall.

Further indications of the value of this technique came from observing the behaviour of these animals when given access to a small hand-mirror in the cage or lying on the floor of the room. Here the monkey is able to move the mirror about, and the fascination of it to them was strikingly apparent. Indeed, its interest for the young ones in particular was such as frequently to counteract the attraction of preferred food items, such as fruit, in the vicinity of the mirror. Further, the two young animals tended to show as much interest in it when they were together as when they were viewing it individually in their cages. In fact, the interest of one in it tended to be accentuated by the investigatory and playful behaviour towards it of the other, so that social facilitation seemed here, as on many other occasions, to be operating strongly.

The typical behaviour of the two young animals, when given the small hand-mirror separately in their cages, has consisted of a wide variety of investigatory behaviour, such as peering close up to it, licking at its surface, chewing the edge of it, pawing at its surface, picking it up and holding it in one hand or both hands, usually close up to the face, and sometimes putting one hand round to the back of the mirror as though trying to touch the reflected object. Both these animals have also frequently looked obliquely into the mirror, either when holding it up, or when it is lying flat on the ground, and on one occasion the young female 'yawned' while thus looking, and then immediately turned and 'yawned' at the observer whom she had apparently viewed in the mirror.

In a series of trials carried out over several days, and using a variety of different surfaces of the same sized object ranging from completely black to full reflecting, the presentations being randomized to control for serial effects, there is clear evidence of differential stimulating effects according to the degree of mirror-image discernible. It is also clear, however, that there is a gradual habituation to the mirror-image as is shown by the fact that both young animals reduced their investigatory time with the full-reflecting hand-mirror from 100 per cent for each on the first 5-min trial to 60 and 63 per cent respectively on the fifth 5-min trial. There are, however, oscillations with some of the intermediate mirror-surfaces which suggest that the incomplete images may possibly be less subject to habituation than the complete, but these trends need further systematic investigation.

When the hand-mirror has been placed on the floor of the room in which the two young animals have been freed from their cages, it still remains very compelling to them. Thus, the young female immediately on leaving her cage has come straight up to the mirror, peered into it as it lay on the floor, picked it up and held it close to her face, and carried it about with her, even though she was free to climb on the window ledges and look out or explore the rest of the surroundings. The young male also frequently attended closely to the mirror and manipulated it, and often has followed the reactions of the female to it. On one occasion he grabbed the mirror in his hands as she held it to her face and tried to pull it away from her. She then ran away from him on her hindlegs clutching the mirror in both hands. This young female has always had priority of access to preferred food items, such as fruit, when the two young ones have been together. However, when the mirror has also been available to her, she has tended to leave only partly eaten such objects as bananas, and has even tolerated the young male eating a part of a banana very close to her while she has been gazing at her mirror-image.

The reactions of the adult animals, when the hand-mirror has first been placed in their individual cages, have been markedly different from those of the young ones. Thus, when it was placed flat in the food bowl in the adult male's cage, he reacted immediately with startle and jumped away to the back of the cage. The reaction was evidently in response to the mirror-image of himself because it occurred as soon as he stood looking down from directly above it. He then avoided the mirror and went to sit at the back of his cage. Whenever he did glance towards it, his behaviour showed uneasiness in frequent 'yawning' and movements of the lips. It was only after 12 min from the time when the mirror had been put in his cage that he again came and stood looking down on it, and again at once jumped away from it, 'yawned' six times in rather rapid succession, stood on his hindlegs above the mirror, and then gave a series of thirteen 'yawns' at a rate of about one every 15 sec. He continued with this kind of behaviour throughout the whole period of the trial and also climbed around inside his cage very actively. Only after 15 min did he for the first time put one hand out and touch the mirror very gingerly. During the next 6 min he picked up food pellets in his mouth, but without chewing and eating them, merely nibbling at their ends, and he also picked up nutshells that were lying near the mirror.

The adult female's reactions to the hand-mirror likewise showed startle on first perceiving the mirror-image, but then a cautious but more or less continuous investigatory behaviour shown chiefly through peering at the mirror, looking underneath it, twice putting her face right up against its surface, looking briefly into it, but never actually touching it with her hands. For the 5-min period following removal of the mirror from her cage, she continually searched around inside the cage peering several times under the wooden board on the cage floor, looking under the food bowl in which the mirror had been lying, and so on. Thus, in a preliminary way, these observations on these four animals suggested the potential value of a more controlled study with systematic variations of the mirror-stimulus condition.

The first of these studies is described now in outline. A two-sided mirror, 30 in. high by 18 in. wide, was mounted vertically on a wooden four-wheeled carrier, enabling it to be moved readily from one part of the laboratory to another. This mirror, sufficiently large for the animal to perceive the whole of its standing frontal image, was used on experimental trials at varying distances and conditions, while control trials were systematically interspersed with the experimental ones as a check on the effectiveness of the mirror as such rather than of any other conditions surrounding the animals and affecting their behaviour. The control observations were made either when the mirror was set directly in front of the animal in exactly the same way as for an experimental trial except that the mirror-surface was kept covered with a white cloth, or when the mirror was exposed to the direct view of the animal in the next cage but only to the indirect view of the control animal, or when the animal was screened from seeing anything but the usual laboratory environment. Common to all trials, experimental and control, were the presence of the same two observers, and the operation of recording equipment.

The behaviour of the two adult animals, when confronted with the mirror separately and at distances of 3, 6 or 9 ft. from the front of the cage, indicated a high degree of tension in comparison with their behaviour in the control situations. Typically, the adult male stood with body tensed, or sat with his back straight and his head alert, staring into the mirror and 'yawning' repeatedly with the mouth gaping open wide and the head going low towards the ground. The head then tended to jerk back to the normal gazing position. On the first mirror trial with the male, this reaction occurred fifteen times during the first 60 sec, that is, once every 4 sec. On this and subsequent trials on other days, the 'yawning' frequency decreased rapidly to near-zero a minute over the trial period of 10 min. However, as this response waned it gave way to other, and perhaps lower intensity, behaviour patterns, also indicative of tension. Thus, the male began repeatedly to pick up in his fingers the standard food pellets lying in a bowl in his cage and rubbed them repeatedly and for several seconds with a rolling motion between his two hands before nibbling the end of the pellet, without actually chewing any of it off, then finally letting the pellet drop to the floor and picking up another.

From observation of his normal undisturbed feeding behaviour with these pellets, it is clear that the rubbing is far in excess of that which he usually adopts with this food object, and it is also obvious that the nibbling and discarding of the pellets in this way is an unusual procedure for this animal. When engaging in this kind of 'false' feeding behaviour, the male sat sideways on to the front of the cage, so that he avoided seeing the mirror-image. In normal feeding, he tends to face towards the front of the cage.

Another indication of tension in the adult male's behaviour to the mirror seemed to be an increased frequency of self-scratching, as opposed to self-grooming, occurrences. Self-grooming is a leisurely picking-over of fur and skin, while self-scratching has here been a brief episode of rapid, dog-like scratching; for example, of the back of the neck by the hind foot. To what extent the mirror situation has affected the sexual behaviour of this animal is not yet clear; but it is possible that the observed occasions of erection of the penis and of masturbation during the experimental trials were brought on by the conflict nature of the situation.

As a variation, the vertical mirror was once placed at a distance of 9 ft. from the front of the adult male's cage, uncovered, and then moved slowly by the experimenter towards the cage. This elicited a dramatic and highly intense series of reactions. During the first minute, as the mirror was approaching him, he stood close to the front of the cage and 'yawned' 23 times, that is, at a frequency of 1 in about 2·5 sec. Thereafter, the 'yawn' frequency decreased sharply, giving a total for the 10-min trial of 67. When the mirror was right against the front of the cage, the cage door was slid aside so that there was no barrier between the male and the image. The effect of this was instantaneous, the animal at once striking repeatedly at the mirror with both hands, trying to bite at its surface, and pressing hard against it. This hand-scrabbling and pressing of the face towards the mirror, interspersed with occasional 'yawns', continued throughout the trial, except for brief intervals during which he scratched and sometimes picked up food pellets from his bowl but threw them immediately aside. When the mirror was moved away at the end of the trial, he continued to move restlessly about his cage, climbing around it, as though attempting to get out, and standing on hindlegs looking around the room. This approach trial was, as would be expected, much more effective in arousing intense and varied behaviour than the trials where the mirror was static.

The adult female, when shown the mirror at a fixed distance in front of her cage, 'yawned' 14 times only in the first trial. This can be compared with the first trial frequency of 50 for the adult male. 'Yawning' was thus not the most prominent response of this animal to the mirror. Rather was her behaviour on the experimental trials characterized by cautious investigation, as shown by her low crouching postures, peering towards the mirror, looking continually around her cage, around the room, up to the ceiling and towards the cage of the adult male. Her agitation or uncertainty was, however, indicated by an enormous increase in frequency of self-scratching episodes during the experimental, as compared with the control, trials. On one trial, frequency of this response built up to a peak as her 'yawning' frequency waned, and 43 separate scratching episodes were observed in the 10-min trial, as compared with an average of 8 or less in control conditions.

This female's behaviour was markedly oriented much of the time towards the adult male on those experimental trials where the screen between them was removed, enabling them to see each other. She repeatedly looked toward him, and he showed a high degree of alertness, standing repeatedly on hindlegs, gazing out in the direction in which she was looking, and occasionally 'yawning'. It seemed thus that he was responding, not to the 'common stimulus' provided by the mirror-image, for that was not visible to him, but to the agitated and watchful behaviour of his female partner. The mirror technique, used in this way on a pair of animals, seems to offer one simple way of studying in the laboratory what Miller, Murphy and Mirsky[4] have called 'communication of affect'.

The two young animals have only so far been given the vertical mirror when they are free together in their large living cage. The immediate effect of the mirror being placed in this cage was to inhibit their vigorous play-activity, including sexual play such as mounting, biting, etc., and to concentrate the attention of both animals on the mirror itself. Therefore, far from being an attraction only for an isolated animal, as Yerkes and Yerkes[1] have suggested, it has seemed to have an effect perhaps comparable with the first introduction of a new monkey of about the same age as the two others. The young female, in particular, scarcely ever left the vicinity of the mirror while it was in the large cage, and, when she had peered into it, she scraped at its surface with her hands, and put her face right against it. She then continually walked round and round the mirror rather slowly and cautiously, looking at it from all angles. The young male, although also interested in the mirror, as indicated by his gazing full into it and waving his arms towards his own image, tended rather, as in other performances when the two have been together, to follow the female around, and hence to do more or less what she was doing.

The frequency data on the distinctive behaviour patterns, such as 'yawning', scratching, fumbling with food pellets, etc., may all, it seems, be used in full-scale experiments to indicate significant trends in the reactivity of the animals to the many variations made possible by the mirror technique. The study of habituation is itself, in the primates, a neglected aspect of learning. Our own preliminary data, using 'yawning' as the response selected for special attention because of its prominence, show a progressive waning in frequency over successive days, as well as within 10-min trials as from the first to the last minute. When more than one experimental trial has been carried out on the same day, the habituation effect has been even greater, and it is probable that it would turn out to be proportional to the time-interval elapsing between the end of one trial and the start of the next. Two further points are suggested by the results. First, if an interval of 24 h occurs between the end of one experimental trial and the beginning of the next, there is a fairly marked initial increase in the frequency of the 'yawning' response. Secondly, as habituation of the adult male to his mirror image progressed, so his more or less complete lack of response to the control situation of covered mirror or mirror to the side of his direct view has tended to alter. Thus, on the first control session, no 'yawns' were recorded, while 50 were recorded in the first experimental session. On the

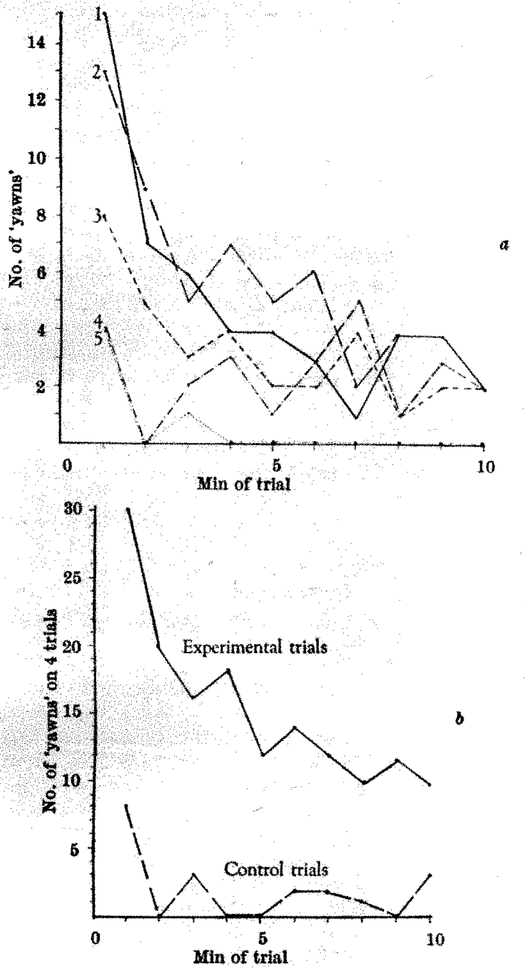

Fig. 1. No. of occurrences of 'yawns' by adult male

——, Day 1; — — —, day 2; - - -, day 3; - · -, day 4; · · · ·, day 5

fifth day from the beginning of experiments, the mirror elicited only 5 'yawns', four of them being in the first minute of the trial, and the control situation elicited 13 'yawns', but these were rather evenly spaced throughout the course of the trial. It would thus seem that, with the habituation to the mirror-image, there is a conditioning of agonistic responses to the mirror-when-covered or to the situation in general, which therefore come to elicit a rather greater general level of tension than the normal. These statistical trends are illustrated in Fig. 1, but it is clear that a complex of social and motivational factors must be operating in these animals which may affect all aspects of their behaviour towards the mirror-image. Thus, it is perfectly possible that the œstrous condition of the female may affect her behaviour towards it, as also may her proximity or otherwise to the adult male with whom she is on intimate relationships. Similarly, the reactions of the adult male to an apparent image of another adult male might be expected to vary considerably according to the social context.

These preliminary observations suggest that the mirror technique, with its potentialities for experimental variation and for standardized presentation of 'social' stimuli, may be usefully developed to sample the behaviour of such animals in the restricted setting of laboratory space. Some of the learning processes involved in social approach and avoidance behaviour, highly complex in the natural group situation, can, it seems, with the aid of this technique, be selected for systematic experimental investigations which may help to bridge the gap between field and laboratory findings on non-human primate behaviour. At least in this way realistic situations can apparently be given to the animal so that they elicit a variety of conflict, frustration, and investigatory behaviour-patterns, in circumstances where they can be objectively and quantitatively recorded.

The research programme of which this investigation is a part was supported by a grant from the Medical Research Council, and I thank Mrs. M. J. Goswell, research assistant under this grant, for the considerable help she has given me throughout the study. I also thank the Wellcome Research Laboratories at Beckenham for their generous gift of two patas monkeys.

DYNAMICS OF THE MEMBRANE OF *AMOEBA PROTEUS* STUDIED WITH LABELLED SPECIFIC ANTIBODY

By Dr L. WOLPERT and C. H. O'NEILL
Zoology Department, King's College, University of London

THE turnover of the surface membrane of cells, in the sense that membrane material is both added to and removed from the surface, is an essential feature of a variety of cellular processes, and is particularly evident in pinocytosis, phagocytosis, vacuolar secretion and cell division[1,2]. Rapid formation of new surface membrane has also been implicated as an essential feature in amoeboid movement[3–5] and it is particularly with this problem that we have been concerned. Controversy exists as to both the behaviour and role of the membrane in amoeboid movement. Goldacre[3,4] has suggested that the main body of the surface is stationary and that the membrane contracts at the tail, passing into the cytoplasm, while new surface is formed at the tip of advancing pseudopods—the cell completely renewing its surface as it moves through its own length. The contraction of the ectoplasmic gel at the tail is supposed to provide the force for amoeboid movement. Bell[5] has suggested that formation of new surface at the advancing tip provides the force for pseudopod extension. On the other hand,

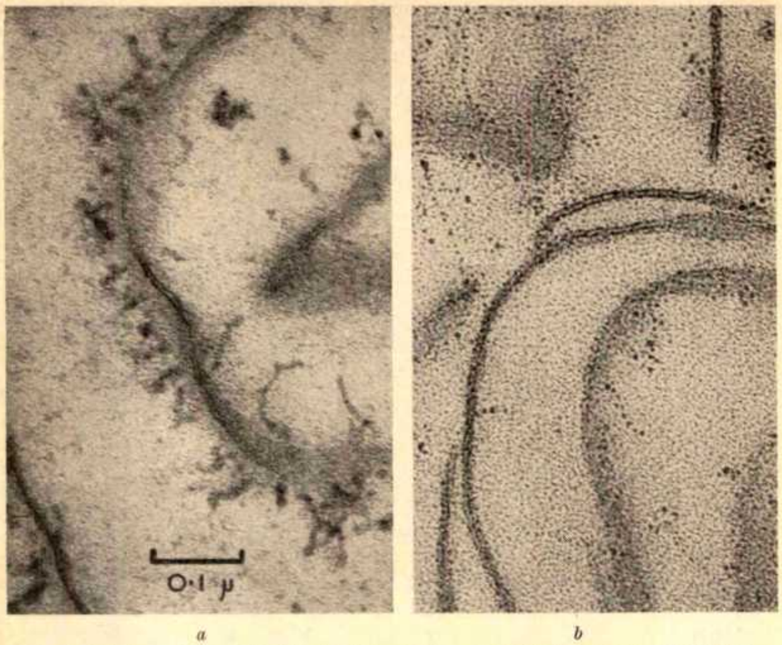

Fig. 1. Electron micrographs of isolated membranes. *a*, Isolated membrane preparation of *Amoeba proteus*, showing the 80 Å double membrane covered with hair-like projections, about 1000 Å long, on its outer surface. Fixed in osmium and stained with lead. *b*, Isolated membrane preparation, treated in the ultrasonic disintegrator for 3 sec. Only the double membrane remains, in 1μ fragments, and the hair-like projections have been dispersed. (*Photo: Dr. E. H. Mercer*)

Mast[21], and more recently Griffin and Allen[6], suggest that the membrane is 'fluid' and that the surface flows forward passively to accommodate changes in shape. Allen has also argued that the force for movement is provided by cytoplasmic contraction at the advancing end[7]. As regards pinocytosis, it is quite clear that membrane leaves the surface[8-10] in the form of pinocytic vesicles and the question is whether there is, during pinocytosis itself, any actual formation of new membrane at the surface. Chapman-Andresen[11] has suggested that no membrane need be formed at the surface itself during the period of pinocytosis, and that the surface area decreases and is the limiting factor.

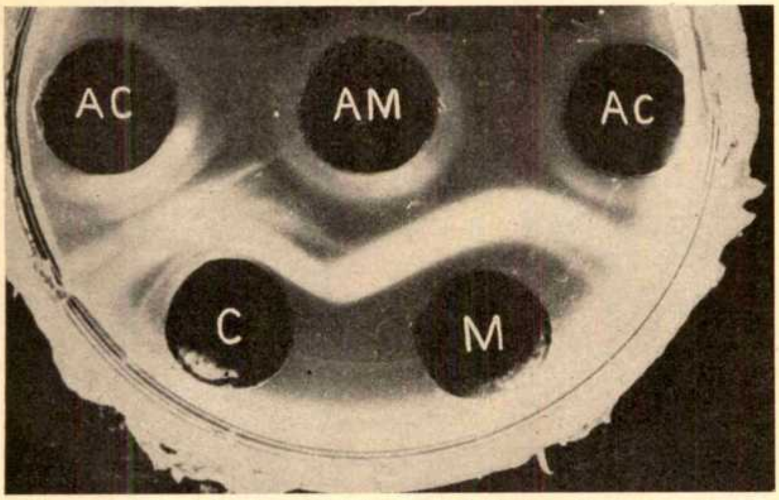

Fig. 2. Precipitin reaction in gel (Ouchterlony plate), showing a single main antigen in the membrane preparation, with traces of two other components *M*, Sonicated membrane; *C*, sonicated amoebae; *AM*, antiserum to membrane; *AC*, antiserum to amoebae

One of the difficulties in investigating turnover of the surface membrane has been to label satisfactorily the cell surface so as to determine the rate and site where new membrane may be formed. Results of investigations of total lipid turnover[1] are difficult to interpret in this connexion, as one cannot distinguish between lipids in the surface membrane and those elsewhere in the cell. Our recent isolation in bulk of the surface membrane of *Amoeba proteus*[12] provides a means of obtaining such data on membrane turnover, and our first approach has been to use a fluorescein-labelled antibody specific to the membrane with which to label the membrane and then to observe its behaviour during locomotion and pinocytosis.

Specificity of the Labelled Antibody

The surface membrane of the amoeba is quite stable and may be recovered from a variety of salt solutions after gentle homogenization of the amoebae. Such membranes are usually contaminated with cytoplasmic materials not easily removed. The method we have used largely avoids this difficulty. Amoebae placed in high concentrations of glycerol or sucrose appear after several days as membranous bags containing a clump of cytoplasm, and the membranes may be separated from the cytoplasmic lump by gentle homogenization followed by differential centrifugation to give a quite pure pellet of membranes[12]. Electron micrographs of isolated membranes (Fig. 1) showed that the membranes are very similar in morphology to those observed in intact cells[12,13]. The membrane comprises a typical lipoprotein or plasma membrane, appearing as a double layer about 80 Å thick, together with a thick coat on its outer surface. This coat shows itself to consist of fine hair-like projections about 1000 Å long and 100 Å thick (Fig. 1*a*). The membrane is periodic acid–Schiff positive[14] and this is ascribed to polysaccharide in the outer coat. Preliminary biochemical studies of the isolated membranes indicate that they contain about 32 per cent lipid, 15 per cent sugar, of which 3·5 per cent is amino-sugar, and 25 per cent protein. A wide range of amino-acids is present but only three sugars—hexoses—have been found, and one of these, as yet unidentified, is the major component. Sialic acids are absent[15].

Antisera to the isolated surface membranes have been prepared by injection into rabbits of supersonic homogenates (5 mg) of lyophilized membrane incorporated in complete Freund adjuvant[16]. Double diffusion in agar gel (Ouchterlony) of the sera obtained indicated the presence of a single reacting system, when the membrane antigen was treated supersonically. Without supersonic treatment the membrane is insoluble and no lines of reaction appeared, and examination of sonicated membranes in the electron microscope showed that the surface coat had been dispersed, leaving only fragments, about 1μ long, of intact plasma membranes (Fig. 1*b*). The reaction of sonicated membranes with sera elicited by whole cells again elicited only one main line, and this showed a reaction of identity with that against membrane antiserum, and with one of the 10 or more lines formed between whole cell serum and whole cell homogenates (Fig. 2). These and other reactions, which will be reported in detail elsewhere, suggest that the antibody to the isolated membranes is elicited mainly by the surface coat, and that the surface coat contains one main antigen which is also found in whole cells.

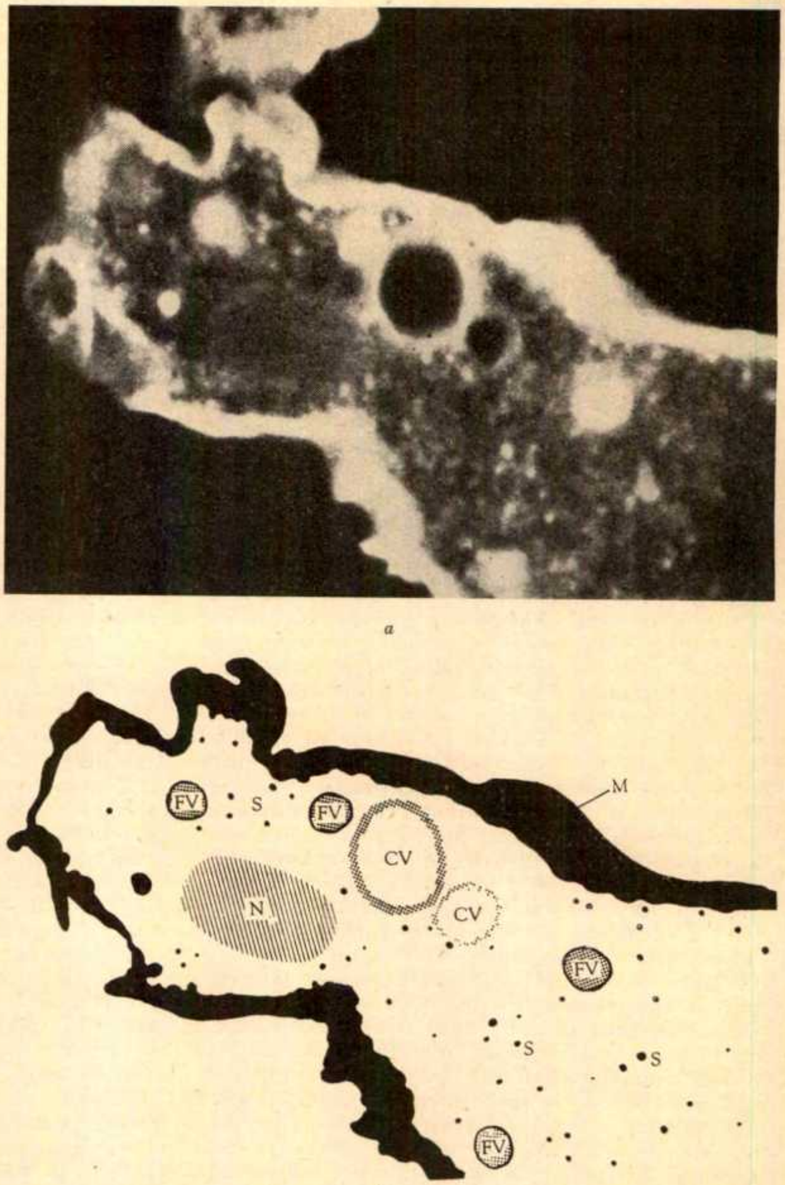

Fig. 3. *a*, Monochrome reproduction of photograph of portion of an amoeba section, treated with fluorescent specific antibody and viewed in ultra-violet light. *b*, Diagram indicating distribution of colour in *a*. Solid areas indicate localization of specific membrane antibody, at the cell surface and at certain sites within the cytoplasm. Shaded areas indicate autofluorescence, particularly strongly emitted by the contents of the food vacuoles

M, Cell surface; *CV*, contractile vacuole; *N*, nucleus; *FV*, food vacuole; *S*, localized sites of antibody staining

The specificity of the antibody was further demonstrated by treating cell sections with fluorescein-labelled antibody. Sera were first fractionated with 50 per cent saturated ammonium sulphate and the globulin fraction thus obtained treated with fluorescein isothiocyanate[17]. Non-specific sera were prepared in parallel. After removal of excess flourescein by dialysis, 0·5 per cent bovine albumen was added to protect the globulin, and the volume of the solution adjusted to a total protein concentration of 1 per cent. The resulting fluorescein-labelled antibody to the surface membrane reacted strongly and mainly with the cell surface, as seen in freeze-substituted sections of whole cells (Fig. 3*a*), and also with certain localized sites within the cytoplasm. The yellow-green fluorescence of the fluorochrome is readily distinguishable from the fainter blue-white autofluorescence of the cell. Some of the fluorescein-stained sites can be identified with food vacuoles, but the majority are much smaller—within the size-range of pinocytic vesicles. Stratification of the cells by centrifugation before fixation causes these smaller sites to form a band at the level of the nucleus, and such cells show no other staining within the cytoplasm. That the cytoplasmic sites are similar, antigenically, to the membrane and that their staining does not indicate cytoplasmic contamination of the isolated membranes is suggested by investigations in which the antibody is previously absorbed with either intact whole cells or cytoplasmic fractions. In both cases the reduction in staining intensity of the membrane was paralleled by that of the cytoplasmic inclusions. No staining whatsoever was obtained in cells treated with the control labelled globulin. Living cells were injected with the specific labelled antibody by Dr. C. Hoskins. The stain was initially uniformly distributed throughout the cytoplasm but could not be detected in the nucleus, food vacuoles or contractile vacuole. At no concentration was there any evidence for the staining of specific sites within the cell, neither at the inner face of the surface membrane nor at any sites within the cytoplasm. Cells maintained apparently normal locomotion, and within a few hours the stain accumulated in vacuoles and was defæcated in a manner similar to food remnants[9]. Cells injected with labelled non-specific antibody behave in a similar manner. The absence of staining of specific sites when the membrane specific antibody is injected into live cells in contrast to the staining shown on sections is possibly due to the main antigenic sites being located on the outside of the surface membrane and on the inside of vesicles, thus making them inaccessible to the antibody.

It is therefore concluded that the antibody prepared in the way described is directed exclusively against macromolecular entities contained within the surface membrane of the amoeba, and also found in certain cytoplasmic vesicles. One major component of the antibody is directed against the surface coat, which is probably a mucoprotein.

It is of interest that five strains of *Amoeba proteus*, and also strains of *Amoeba discoides* and *Pelomyxa carolinensis* reacted positively to the antiserum; strains of *Amoeba dubia*, *Hartmanella rhysodes* and a species of *Acanthamoeba* did not react to the antiserum.

Behaviour of Labelled Cells

If cells are placed in a 1 : 10 dilution of the labelled antibody for 5–7 min, and then washed in culture medium, the cells soon begin to locomote apparently normally. Their surfaces fluoresce brilliantly and there is no evidence for any staining within the cell. Longer exposure of the cells to the specific antibody leads to pinocytosis after about 30 min. Neither control labelled globulin nor fluorescein labels the cell surface. In locomoting labelled cells the surface fluorescence appears to be substantially uniform over the whole of the locomoting cell; an apparently greatly increased intensity at the tail of some cells is largely accounted for by the greatly increased folding and nodulation of the tail surface which is visible using the *N.A.* 0·95 objective. Examination of the tips of advancing pseudopods, in particular, shows a uniform thin surface fluorescence. There is thus no evidence for rapid surface renewal at this point or at any other region of the cell. Cells that had moved through a distance many times their own length still showed uniform labelling over their surface. On occasion pinocytic channels were seen at the tail.

Slowly, over a period of hours, the cells showed a reduction in surface labelling that was paralleled by an increase in cytoplasmic labelling, which appeared as small fluorescent vesicles. This could be seen both in living cells and in whole mounts of freeze-substituted cells, fixed at 2-h intervals after labelling. The stain gradually accumulates in one or more larger vacuoles and after about 12 h all the stain has disappeared from the surface. This phenomenon is well illustrated by restaining such cells, which again show bright surface fluorescence, which again disappears over 24 h and accumulates within vacuoles. This procedure was repeated five times, each time with the same result. The cells survive at least another week during which time the vacuoles are defæcated[9]. While fluorescent labelling is notoriously difficult to quantify, the time required to halve the intensity of the surface stain was estimated to be about 5 h.

These results suggest that there is no rapid turnover of the surface membrane during locomotion such as would be expected if the cell surface were reformed anew each time the cell passed through its own length[3,4], that is about every 2 min. There is, however, a slow turnover with a time-scale of hours. The rate of disappearance of the stain from the surface will be exponential if: (1) there is continual removal and formation of surface; (2) the surface area remains constant; (3) there is complete mixing of old and new surface; (4) stain that leaves the membrane does not enter it again. Our observations suggest that these are reasonable assumptions. Then, if the amount of stain in the membrane is halved after 5 h the rate of membrane renewal and formation is 0·2 per cent/min.

The persistence of the uniform distribution of the labelled antibody on the cell surface as it moves forwards suggests that the surface behaves as a fluid envelope, which flows forwards to accommodate the changes in shape of the pseudopods. This is in complete agreement with the conclusions based on observations of particles attached to the surface[6,21]. This argues strongly against either membrane contraction, accompanied by re-entry at the tail, or formation of new surface membrane at the advancing tip.

Those experiments purporting to demonstrate that the surface is stationary during locomotion and is resorbed at the tail and formed anew at the front are by no means convincing[3,4]. The accumulation of cationic dyes at the tail of the amoeba which has been suggested as showing the resorption of the membrane into the cytoplasm there[3] is open to other interpretations and may be due to the electric potential gradient along the amoeba[18]. Those experiments in which glass fibres or oil drops were applied to the surface and were found not to move forward[4] are also equivocal. These objects only offer local obstruction to membrane flow, and thus cannot show that the whole membrane is stationary.

Normal locomoting amoebae have a well-defined tail, easily recognized by its wrinkled appearance. Evidence was obtained to show that the tail region behaves differently from the rest of the surface. Labelled antibody was applied locally to a small region of the cell surface by drawing the cell into a narrow capillary and briefly immersing its tip in concentrated antibody solution. This resulted in a cell with a local area showing brilliant staining and the remainder of the cell showing no staining. Cells treated in this way recovered at once and performed apparently normal locomotion, and the stained region became the tail in all cases. The staining of the tail persisted over a period of 1 h before it finally dispersed. Observation of the margin of the stained area revealed occasional abrupt separation of small islands of stain within the membrane; these moved quickly forward towards the advancing pseudopod and at the same time rapidly expanded and dispersed. This process was only briefly visible since the intensity of fluorescence decreased rapidly as it spread. These observations, showing relatively little surface flow at the tail compared with the rest of the cell, are supported by our observations on particles attached to the tail. These are carried passively along for periods of many minutes and, unlike those elsewhere on the surface, do not move towards the advancing end. Again, centrifugation of amoebae—at 10,000g for 10 min—sometimes results in the appearance of a small stationary pseudopod at the tail. This remains there without change of shape, during active locomotion, for periods up to 1 h. The tail thus seems to be a region in which the surface does not flow forward and seems to be carried passively along. This view is again in marked contrast to that of Goldacre[4], who suggests that there is both contraction and resorption of membrane at the tail.

Amoebae labelled with specific antibody were also examined as regards pinocytosis and phagocytosis.

In 0·125 M sodium chloride (pH 6·0) and 2 per cent albumen (pH 5·0), pinocytosis of labelled cells was both quantitatively and qualitatively similar to the controls, but in 0·2 mg/ml. ribonuclease pinocytosis seemed to be reduced. Fluorescent pinocytosis channels could be seen. When pinocytosis was ceased —after about 20 min—the surface of the cell was still brightly stained. Labelled cells phagocytosed tetrahymena, and the surface of the food vacuoles was clearly fluorescent. This is in accord with the results of other workers, which show that the surface membrane of the cell gives rise to, and is morphologically very similar to, the membrane of newly formed food or pinocytic vesicles.

Since the cell surface was still stained after membrane had left the surface during pinocytosis and phagocytosis, it seems that no new membrane is formed during these processes, and this is in accord with Chapman-Andresen's[11] conclusions that the availability of membrane is the limiting factor for pinocytosis and that the area of the surface membrane is reduced during pinocytosis by the area of the pinocytic vacuoles that are formed. Moreover, her observation that after pinocytosis the surface area of the membrane is reduced by about half and the cells require a recovery period of about 4 h before they can complete a comparable amount of pinocytosis again, may indicate the time required for the formation of new membrane. This corresponds quite satisfactorily with our figure for membrane turnover of 0·2 per cent/min, since, if re-entry of membrane into the cell ceased, renewal of half the surface area of the membrane would then require 4·2 h. The inability of the cell to form new membrane rapidly is again suggested by the fact that when cells are cut up into about 16 fragments, each shows uniform surface labelling and further attempts at subdivision lead to cytolysis.

Discussion

It thus appears that the surface of the amoeba is fluid, except at the tail, and though there is no rapid formation of new surface membrane, there is a slow turnover. Consideration of the specificity of the antibody suggests that these conclusions may apply to the surface coat only, and one must now consider to what extent its behaviour represents that of the membrane as a whole and, in particular, the plasma membrane.

There appear to be two main possibilities. Either the membrane flows forward as a whole and there is a zone of shear between it and the stationary ectoplasmic gel[7], or the surface coat only is fluid and flows over the plasma membrane which is stationary, and the zone of shear is within the membrane itself. While the first possibility requires no formation of new membrane during locomotion, the second requires that the plasma membrane be formed anew each time the cell passes through its own length as suggested by Goldacre for the membrane as a whole[4].

This second alternative seems improbable for several reasons. If the continuity of the plasma membrane is to be maintained, and the electron microscope evidence suggests that it is, then all the components of the membrane beneath the flowing surface coat must be intussuscepted at the advancing tip and resorbed at the tail. There is no persuasive evidence that this complex series of events is taking place. Also the zone of shear must be localized within a very narrow zone—less than 0·5μ—within the coat, or at the junction between the coat and plasma membrane. This seems improbable, if only in view of the high viscous drag that would result if the zone of shear were restricted to a narrow region in a membrane showing both continuous and radially oriented structure in the electron microscope. We thus prefer the far simpler possibility that the coat and membrane are attached and both flow forward except at the tail. This requires that the zone of shear would be in the hyaline fluid layer that is present between the membrane and the gel[7]. While this fluid may be expected to provide only a low viscous drag, one might expect that one could find evidence for the flow of fluid forwards in the outer region of this layer. We have no evidence for this, but such a flow could well be obscured by the backward movement of the whole hyaline zone[19]. However, it is clear that the membrane moves as a whole during pinocytosis and phagocytosis, since both main components of the membrane are found in food vacuoles and pinocytic channels and vesicles[8–10].

Irrespective of whether the whole membrane or only the outer coat flows forward, the fact that the labelled antibody on the surface enters the cell over a period of hours shows that the membrane slowly both enters the cell and reforms at the surface. Our suggestion is that entry is brought about by pinocytosis at the tail. If pinocytosis goes on slowly at the tail in locomoting amoebae, both the slow turnover of the membrane and the difference in surface behaviour between tail and the rest of the amoeba may be accounted for. Pinocytosis seems the most likely mechanism for the entry of large molecules such as are contained on the surface of the amoeba, and we have observed pinocytosis at the tail of labelled cells, and the gradual appearance within the cytoplasm of numerous small labelled inclusions, probably pinocytic vesicles. At this stage we do not know how much of the pinocytosis at the tail is induced by the application of the labelled antibody itself, but evidence for a similar process in unlabelled cells is suggested by: (1) the presence of small sites, possibly pinocytic vesicles, within the cytoplasm which stain with specific labelled antibody; (2) the highly convoluted surface at the tail; (3) when pinocytosis is induced it usually starts at the tail[8]. All these emphasize the similarity in the state of the membrane at the tail of a locomoting amoeba, and the whole membrane of one which is pinocytosing. It is also pertinent that Bird has observed both pinocytosis and phagocytosis to occur normally at the tail of entamoebae[20].

As regards re-entry of membrane into the surface, we have almost no idea how this occurs nor even in what form—vesicular, micellar, or molecular—the constituents enter the surface membrane. The fate of pinocytic vesicles is unknown. It is possible that the vesicles may fuse directly with the membrane to provide new surface, or they may contribute to the membrane of the contractile vacuole which might provide new surface material since it empties by fusion with the surface membrane. If our conclusions as regards turnover are correct then attention must be directed to slow, rather than fast, formation of new surface membrane, and it would be of great interest to obtain data on other cells and to establish whether fast formation of new surface membrane can occur.

Our results show that those theories of amoeboid movement that require rapid formation of surface at the advancing end, or contraction and entry at the tail, are unsatisfactory. Since the membrane of the amoeba appears to be fluid and flow forward passively, it seems that the forces responsible for amoeboid movement must originate at some site other than the surface membrane. However, the membrane may play an extremely important part as regards the control of movement. This has already been pointed out in relation to the bioelectric potentials across the membrane, which may control the direction of movement[18]. It is possible that the flow properties of the membrane may also be a feature of some importance in locomotion, pinocytosis and phagocytosis. For example, pinocytosis may be associated with reduced membrane flow, and new pseudopod formation may result from an increased fluidity of the membrane.

We thank Prof. J. F. Danielli for his encouragement and advice; Dr. E. H. Mercer, of the Chester Beatty Research Institute, for the electron microscopy; Dr. C. Hoskins (National Institutes of Health postdoctoral Fellow) for assistance with micrurgy; Dr. E. A. Barnard and C. M. Thompson for helpful discussions; and Mrs. J. L. Stewart for culturing the amoebae. The work was supported by the Nuffield Foundation.

OBITUARIES

Sir John Edgell, K.B.E., C.B., F.R.S.

VICE-ADMIRAL SIR JOHN AUGUSTINE EDGELL died in Salisbury on November 14. He was the younger son of the late James Edgell of Teddington, and was born on December 20, 1880. He joined H.M.S. *Britannia* at the age of thirteen and, nine years later, specialized in hydrographic surveying. His first ship, as sub-lieutenant, was H.M.S. *Triton* surveying in the North Sea.

In 1912 he was given his first command, H.M.S. *Mutine*, and served for the next two years on the west and south coasts of Africa. Later, he commanded H.M. Ships *Triton*, *Hearty*, *Endeavour*, *Merlin* and H.M.A.S. *Moresby*. His surveying duties took him to most parts of the world, and he was in charge of surveys in China, Australia, the Red Sea, Mediterranean and the south and west coasts of Africa. He was promoted to commander in December 1915 and two years later became superintendent of charts, which post he held for two years. After a period at sea, he returned to the Admiralty as superintendent of charts during 1923–25. He was promoted to captain in 1923.

Edgell held the appointment of assistant hydrographer during 1928–30 and again during 1931–32; the intervening period he spent in command of H.M.S. *Endeavour* in the Red Sea. He became hydrographer of the Navy in October 1932 and held this post for the next thirteen years, a term only exceeded by Admirals Beaufort and Wharton. He carried the burden of this appointment throughout the Second World War. His service as superintendent of charts during the First World War stood him in good stead, and the experience he gained of the chart production unit in H.M.S. *Endeavour*, during the Dardanelles Campaign, led to similar equipment being installed in H.M.S. *White Bear* for service in the Burma campaign during 1943–45.

Shortly before the outbreak of war in 1939, plans had been made to transfer the Admiralty Chart Establishment at Cricklewood to a specially designed building, equipped with up-to-date rotary offset printing machines, at Taunton. The move did not take place until 1940, and the Cricklewood establishment suffered damage from the early air raids; but output was not affected. In accordance with general policy, the Chart Branch, situated in Cornwall House, London, S.E.1, was transferred to Bath shortly after war broke out and, at the same time, expanded enormously to cope with the extra demand for special charts. When the Production Division was set up at Taunton, the Issues Division also moved to Taunton from London, and, being under the same roof, was able to cope with the enormous increase in demand for charts, now turned out at a far greater speed on the new presses.

Edgell was most energetic throughout the War in meeting all the calls made on the Hydrographic Department and enjoyed great foresight in planning and preparing new types of charts for the ever-growing tempo of the War. Among his most successful innovations were the chart maps prepared originally for the landings in Sicily and which later were invaluable for the Normandy landings.

His surveying ships and detached officers were engaged in all theatres, from Norway to Burma, and carried out their work inspired by his leadership at the Admiralty.

His horizon was wide and he kept himself fully up to date with modern developments, though his service had begun in the days of sail and sounding under oars. He pressed forward with the introduction of echo-sounding equipment so that, in 1939, the new surveying ships he had done so much hard work to obtain were fitted with the latest types capable of obtaining soundings as deep as 1,000 fathoms.

He was promoted to rear-admiral in 1939 and to vice-admiral in 1938 and placed on the retired list; but he continued in this rank for the next seven years, finally relinquishing his post as hydrographer in May 1945.

During his term of office, the need for better knowledge of the oceans was essential for submarine warfare, and an Oceanographic Section was set up within the Hydrographic Department. With his usual foresight, he realized that Great Britain seriously lacked a centre for research in this subject, and in 1944 he opened discussions in the Admiralty which eventually blossomed, six years later, into the National Institute of Oceanography. After retirement from the Navy, he kept himself fully abreast of all developments and served on the National Oceanographic Council and Executive Committee of the Institute, where his counsels were highly respected. He attended his last committee meeting as recently as June of this year, after which his health began to fail.

For his services in command of surveying ships during the First World War he was awarded the O.B.E. in 1919. In 1936 he was made C.B., and was created K.B.E. in 1942.

But his proudest moment was when he was elected to the fellowship of the Royal Society in 1943.

Edgell was, from its beginning, very closely connected with the activities of the International Hydrographic Bureau and attended four of the quinquennial conferences at Monaco, and in 1939 was elected chairman of the Assembly.

Edgell was appointed by the Admiralty to the Board of the Port of London Authority in 1941, and held this post until his seventieth birthday and was nominated as the Authority's representative on the Kent River Board. He was selected to be the acting conservator of the Mersey on retirement as hydrographer until 1951.

Always a keen cricketer, Edgell lived an active life. Many were his tales of hard work and full enjoyment in his sea-going days, when there was no easy substitute for marching through rough country to make a triangulation station or pulling a whaler for weeks on end to sound out the shallow areas of a survey. He took a very personal interest in his officers and men and would always be forthcoming in giving advice and encouragement. His knowledge of hydrography was unlimited, and he had a flair for imparting his skill, while his memory never failed him for even the most precise point of detail.

He was the last of the old generation of surveyors who had been brought up on the tenets of Wharton and Field and the hard life that the early surveyors had endured.

E. G. Irving

Prof. T. M. MacRobert

Thomas Murray MacRobert died at his home in Glasgow on November 1 at the age of seventy-eight. He held the chair of mathematics in the University of Glasgow from 1927 until 1954, and before that had been assistant and lecturer in the same University. He was educated at Irvine Royal Academy and the University of Glasgow, where he graduated in 1905 with first-class honours in mathematics and natural philosophy. From 1906 until 1910 he was a Major Scholar at Trinity College, Cambridge, and was a Wrangler in the Mathematical Tripos.

Prof. MacRobert was the author of numerous papers on the theory of special functions, on which he was an expert; he continued to be active in research until just before he died. Much of his work was concerned with the properties of E-functions; these functions, which were invented by him, contain as special cases several of the well-known functions of mathematical physics, and make it possible to give a unified treatment of the subject. His books on *Functions of a Complex Variable* (Macmillan, 1917) and *Spherical Harmonics* (Methuen, 1927) were widely used by students, and he also collaborated with other writers in books on Bessel functions and trigonometry. He was responsible for the second revised edition of T. J. I'A. Bromwich's *Infinite Series* (Macmillan, 1926). The value and popularity of these works are attested by the number of different editions in which they have appeared.

He was a friend and helper, not only to generations of Glasgow students, but also to many mathematicians from India and the East, who will sorely miss the willing assistance he gave them in their work, without ever expecting any acknowledgment. He was one of the original founders of the Glasgow Mathematical Association, of which he was twice president and latterly honorary president. The flourishing state of the Association and the establishment and reputation of its *Proceedings* are very largely due to him.

His interests outside mathematics included hill-walking and playing the organ, and he took a prominent part in the preparation of the *Congregational Churches' Hymn Book*. The affection and respect in which he was held by friends, colleagues and former students was amply demonstrated when, after his retirement in 1954, they commissioned Mr. Norman Hepple to paint his portrait. This excellent likeness, which the University of Glasgow is fortunate to possess, also conveys something of his character and personality. He will be remembered for his kindliness and unfailing courtesy, but above all for his absolute integrity.

R. A. Rankin

Prof. E. F. Nash

Prof. Eric Nash, professor of agricultural economics in the University of Wales, Aberystwyth, died on October 31, aged fifty-eight. He is survived by a widow, a daughter and a son.

Nash started his academic career with a first in Greats at University College, Oxford, went on to Modern Greats, in which he also took a first, and at one time seemed set for a career in pure economics (in 1930 he published *Machines and Purchasing Power*, which was an essay in monetary theory). But with his appointment to the Ministry of Agriculture in 1934 he turned his attention to agricultural economics, and most of his work was done in that subject either in that Ministry, the Ministry of Food, the Control Commission for Germany, or, since 1946, at Aberystwyth. At the time of his death he was among the two or three best-known agricultural economists in Great Britain. This was a reputation gained not through the volume of his published work (indeed, during his twelve years of Government service he was scarcely able to publish anything) but through the uniformly high quality of his articles, speeches, teaching and contributions to discussions and debates. He was much in demand as a speaker and member of committees (Government and other), and his services were borrowed for quite long periods by the authorities in Jamaica, who were concerned with the low state of agricultural development in that country. He had much to do there with the work of the Institute for Economic and Social Studies.

Nash had no special interest at any time in agriculture as an applied science. It is true that as provincial agricultural economist for Wales he had to devote himself to some extent to the practical problems of Welsh farming, especially on the farm management side, and that as a member of the

National Food Survey Committee he came to have an extensive knowledge of nutrition. But his main interest was in size and structure of British agriculture viewed as a component of the national economy, a subject on which Nash felt that the British agricultural industry was both too large and too expensive. He would not, however, have wished to be remembered only as a critic. Most of his criticisms were accompanied by constructive suggestions; and in particular his sympathy was readily engaged by the difficulties experienced by many small Welsh farmers from their unfavourable environment and insufficient size of farm. Had he lived to ordinary retiring age there is no doubt that he would have done much more writing on this and allied subjects, and that it would have had the same originality and lucidity that were the main features of his work up to the time of his early death.

J. H. KIRK

NEWS and VIEWS

Physics at Sheffield: Prof. G. E. Bacon

DR. G. E. BACON, at present deputy chief scientific officer at the Atomic Energy Research Establishment, Harwell, has been appointed to a chair of physics at the University of Sheffield as from October 1963. The University has decided to experiment with a system in which the headship of the Department of Physics will be held in turn for a period of three years by each of the two professors concerned, and Dr. Bacon will assume the headship on his arrival, under this arrangement. Dr. Bacon was educated at Derby School and Emmanuel College, Cambridge, where he took Firsts in both parts of the Natural Sciences Tripos. In 1939 he joined the Air Ministry Research Establishment and was eventually in charge of a group concerned with ground radar research and development at what was then the Telecommunications Research Establishment, Malvern. He was seconded to Chalk River, Canada, for a period, soon after going to the Atomic Energy Research Establishment, Harwell, and since 1948 has been principally engaged in neutron diffraction experiments. His book on this subject is well known as an important work and he has published numerous contributions in this field. It is expected that Dr. Bacon will continue his work on neutron diffraction with particular reference to magnetic ordering in metals and alloys through arrangements to be made outside the University, and a programme of X-ray experiments designed to elucidate further the electronic structure of molecules and solids will be built up following Dr. Bacon's arrival at Sheffield. Dr. Bacon will bring very wide experience in research on the physics of solids to the chair at Sheffield, and with it energy and enthusiasm for implementing new ideas on the teaching side, particularly on the training of postgraduate students, and it is expected that this aspect of the work of the Department of Physics will build up rapidly over the next few years.

Head of Space Department, Royal Aircraft Establishment: Mr. E. G. C. Burt

MR. E. G. C. BURT has been appointed head of Space Department, Royal Aircraft Establishment, Farnborough, in succession to Dr. A. W. Lines, who has taken up an appointment with the European Preparatory Commission for Space Research. Mr. Burt, who is forty, was educated at Yeovil School and Queen Mary College, University of London, where he graduated with a first class honours degree in electrical engineering in 1943. After serving in the Royal Air Force, he joined the Royal Aircraft Establishment in 1947, where as a scientific officer he worked in the field of computers and servo-mechanisms. He was promoted to senior scientific officer in 1950, to principal scientific officer in 1953, and to senior principal scientific officer in 1955, when he became superintendent of the Dynamic Analysis Division of Guided Weapons Department. During this period he published a number of papers concerned with stochastic processes in control and guidance systems and the theory of optimization, and he was awarded the Navigation Prize for his lecture to the Royal Aeronautical Society on this subject. After the launching of the first Earth satellite in 1957 Mr. Burt took a leading part in the Royal Aircraft Establishment's work on satellite tracking, and the correlation of observation with theory concerning the effects of the Earth's oblateness. On the formation of Space Department at the beginning of this year he was appointed head of its Dynamics Division; he has taken an active part in the Department's work—in particular, on communication satellites, where he has made a number of contributions to attitude control theory and orbital patterns.

British Committee for Biological Education

THE Royal Society and the Institute of Biology have established a Joint Committee to report on desirable changes in the teaching of biology in the United Kingdom. It is hoped that this Committee will, through its representative membership, ensure that the merits of various proposals for changes in syllabuses, examinations and teaching methods can be assessed. The Committee will have close liaison with the group of biologists seconded to the Nuffield Foundation in order to produce texts, teachers' guides, apparatus, films and visual aids for the biological education of children from eleven to sixteen years of age. The membership of the Committee is: Prof. W. O. James and Prof. M. M. Swann (Royal Society); Sir Gerard Thornton and Mr. J. B. Cragg (Institute of Biology); Dr. A. Urie (Ministry of Education—observer); Dr. Lucy Boyd (Scottish Education Department—observer); Dr. H. G. Vevers (Biological Council); Mr. W. H. Dowdeswell (Science Masters' Association); Miss V. J. Evans (Association of Women Science Teachers); Mr. L. C. Comber (Secondary Schools Examination Council). Individuals selected for the Committee from universities, examining boards, technical colleges and teacher training colleges include: Prof. T. A. Bennet-Clark, Mr. D. A. Coult, Prof. G. E. Newell, Dr. T. G. Onions and Mr. L. Wolff. The secretariat for the Committee is being provided by the Institute of Biology (41 Queen's Gate, London, S.W.7).

Research in Cutlery and Stainless Steel

In moving that the Cutlery and Stainless Steel Flatware Industry (Scientific Research Levy) Order, 1962, be approved in the House of Commons on November 22, the Parliamentary Secretary to the Board of Trade, Mr. D. Price, said that the primary purpose of the Order was to increase the industry's contribution from £9,000 a year to just on £14,000. with a concomitant increase in the grant from the Department of Scientific and Industrial Research from £6,000 to £9,000. These resources would be used for research and development projects, a technical inquiry service and the dissemination of scientific and technical information. The main research effort would be devoted to increasing the degree of mechanization in the industry, in which labour represented 50–60 per cent of manufacturing costs, and to reducing the number of manufacturing operations. That programme included research on knife and scissor grinding, on multiple polishing, on abrasive operations and on the metallurgy of the edges of knives and scissors. Only firms with a turnover of £10,000 or more would be called on for an increased contribution, and exemption of the first £3,000 of turnover would reduce the number of firms liable for the levy from 280 to 190. The Cutlery Research Council had been reconstituted, at the request of the Department of Scientific and Industrial Research, as an incorporated body under the title of the Cutlery and Allied Trades Research Association. The annual production of the industry, as defined for the purposes of the Order, was about £10 million and it was exporting about £3·5 million a year.

University of Delhi: Physiology of Reproduction

The Ford Foundation has made a grant of 195,000 dollars to the Department of Zoology, University of Delhi, for expanding the facilities for research and training in the field of physiology of reproduction over a five-year period. Dr. M. R. N. Prasad and Dr. B. R. Seshachar will be the chief investigators in charge of the programme. As part of the activity envisaged in the Ford Foundation grant, the Department of Zoology has organized a training programme consisting of a series of sixteen seminars on physiology of reproduction in collaboration with Dr. Sheldon J. Segal, consultant to the Ford Foundation on reproductive biology. The seminars are given by scientists from India and the United States. The seminar series, which was inaugurated by Dr. C. D. Deshmukh, vice-chancellor, University of Delhi, on October 22, will continue until February 25, 1963.

Scientific Research in France

Increasing expenditure on research in France reflects a growing interest in science. Government assistance on a generous scale is extended to scientific bodies from a special Scientific and Development Fund and, in the field of private enterprise, progressive firms co-operate in setting up research centres. Efforts are also being made to strengthen the ties between the universities and industry. A high-powered Inter-Ministerial Committee on Scientific and Technical Research, under the chairmanship of the Premier, was established in 1958 to advise the Government on the best ways of developing scientific research, implementing scientific equipment programmes and distributing proposed State expenditure on research among the various Government departments. To advise the Committee there is a consultative body of twelve persons (known as the 'Committee of Wise Men') chosen by the Premier. The Centre National de la Recherche Scientifique acts as a co-ordinating body and is available to help all scientists, whatever their speciality and whatever the organization—State or private—for which they work. This body itself administers forty groups of laboratories or research institutes, including low-temperature research at Bellevue, astrophysics at Haute-Provence, atomic synthesis at Ivry, macromolecular physics at Strasbourg, and solar energy utilization at Montlouis. At Beni-Abbès there is a Sahara Research Centre. In the field of medical research, the Pasteur Institute—an independent, non-profit-making body—has about 100 laboratories with 33 divisions covering a wide field. About 18 Pasteur Institutes have been established in Africa, Asia and the West Indies. During the past twenty years, OSTROM (the overseas research organization) has set up many research centres in the tropics, the activities of which range from geophysics and plant physiology to river hydrology and oceanography. The position of scientific research in France is outlined in a publication recently issued by the Secretary-General of the French Government (*France*. Pp. 144. Paris: Secretariat Général du Gouvernement, Direction de la Documentation, 16, rue Lord-Byron, 1962).

Minerva: a Review of Science, Learning and Policy

Besides the text of Sir Eric Ashby's first Chancellor's Lecture to the University of the Witwatersrand, the first issue of *Minerva*, the new quarterly review of science, learning and policy, includes articles by Prof. W. Kornhauser on "Strains and Accommodations in Industrial Research Organizations in the United States"; Dr. A. K. Singh on "The Impact of Foreign Study: the Indian Experience"; and Prof. M. Polanyi on "The Republic of Science: its Political and Economic Theory". There are also summaries of the reports of the Scientific Commission of Pakistan and of the report to the President of the United States on Government Contracting for Research and Development, and the recommendations of the Science Council for the Development of Scientific Institutions in Western Germany (*Minerva*: a Review of Science, Learning and Policy, Vol. 1 (Autumn 1962). Edited by Prof. Edward Shils. Pp. 1–144. (London: C.S.F. Publications, Ltd., 135 Oxford Street, 1962.) Published under the auspices of the Committee on Science and Freedom. Subscription-rate: 20*s*. or 5 dollars a year; single issues, 5*s*.) [See also p. 1241 of this issue of *Nature*.]

Careers in Veterinary Science

A recently published booklet in the series on careers issued by the Ministry of Labour provides a good general account of the prospects offered by a veterinary career (Central Youth Employment Executive. Choice of Careers, No. 111: *The Veterinary Scientist*. Pp. 32 (4 plates). London: H.M.S.O., 1962). The five chapters deal respectively with educational and personal qualities required; training; scope and opportunities; the work of the veterinary scientist; and work with the veterinary scientist. This last chapter concerns the work of the various types of auxiliaries employed privately, in Government services or elsewhere. These are experimental officers, laboratory technicians, animal nurses, dressers, skilled animal attendants, etc. (Booklets

No. 57, *The Medical Laboratory Technician*, and No. 32, *The Civil Service: General Scientific and Technical Posts*, give information about careers other than purely veterinary that are concerned with various aspects of the work.) Good illustrations showing veterinary surgeons engaged in various duties are provided. A breakdown shows the numbers of veterinary surgeons engaged in the various branches of the occupations in the United Kingdom. There are 3,247 in private practice and about 1,000 in salaried occupations. Of the latter, 533 are in the service of the Ministry of Agriculture, 114 in that of Northern Ireland, 213 on the staffs of the veterinary schools, 96 employed by commercial concerns, 27 in the service of the Agricultural Research Council, 27 in municipal veterinary services, 52 on the staffs of various research institutes, and 30 in the Royal Army Veterinary Corps. In addition, there are 315 in the Colonial Veterinary Service serving overseas.

Computer Control in Soviet Steel Mills

THE U.S.S.R.'s most advanced industrial computers are those used for the automation of iron and steel production, according to an article on the application of computers and logical operation devices to the automation of factories in the U.S.S.R. (*Mechanical Engineering*. Academy of Sciences, U.S.S.R., Moscow, 1958. Pp. 383. Order 60-51089 from the Office of Technical Services, U.S. Department of Commerce, Washington 25, D.C. Price 3.75 dollars). The article is one of a collection of seventeen papers on mechanical engineering available in an English translation from the Office of Technical Services, U.S. Department of Commerce. Also included are studies on a vacuum dilatometer for investigating the sintering process of metal powders; a device for studying the characteristics of polymer specimens under tension; and an apparatus for testing the impact hardness of ice under field conditions. Although computers are being used in many ferrous metallurgical processes, the article indicates that their application has not yet been extended to rolling mills. This is explained by "the lack of an adequate study of variable conditions in the mills and the lack of the necessary measuring equipment (tension pickups, pickups for the metal pressure on the rolls, 'floating' micrometers, and strip-speed pickups)". The solution of the problem of automation of rolling mills requires the design of electric models for individual components as well as for the mill as a unit. "Work in designing such electric models is being carried out by several organizations." The report was translated for the U.S. Government through a co-operative Federal agency translation programme co-ordinated by the National Science Foundation.

The Lenin State Library, Moscow

THE library which now bears the name of the Lenin State Library was founded in July 1862 as a part of the Roumyantzev Museum in Moscow. The growth of this library was in no small measure due to the accretion of the 'compulsory' copies of all books published in Russia, for it also possesses a very large number of non-Russian books, and in many ways it can claim to rival the great national libraries in London, Paris and Washington. At the present time, as described by A. Y. Chernyak (*Priroda*, 8, 60; 1962), the Library is well housed in a number of buildings. Chernyak states that there is a staff of 2,000 and that the Library has 200,000 readers using 22 reading rooms, and contains 22 million books, sets of periodicals, microfilms and manuscripts. In 1913 the Library used to exchange books with 90 institutions in 19 countries; at the present time it exchanges books with 2,600 institutions in 80 countries, totalling 250,000 outgoing and 212,000 incoming books. Among the older books the Library possesses very valuable works by Copernicus, Bruno, Pliny and many other famous writers. Its reference section is staffed by a number of specialists and it serves, as does its publication service, a very large community.

Science Museums in Developing Countries

THE International Council of Museums has recently published a small booklet on *Science Museums in Developing Countries* (Pp. vi+66. Paris: International Council of Museums, 6 rue Franklin, 1962. 4 NF.; 7*s*.; 0·80 dollars). It is written by Mr. Frank Greenaway, of the Science Museum, London, with additional chapters by Dr. Torsten Althin, of Sweden, and Messrs. W. T. O'Dea, of London, and W. Stephen Thomas, of the United States. Science is concerned, for museum purposes, with ideas about the nature of the physical universe and those aspects of living things which can be the subject of exact or controlled study. Museums are places where things, both still and in action, are collected together, studied and presented. The handbook is intended to encourage educational authorities in countries which are trying to raise cultural standards to set up museums of science and technology. The main part consists of generalizations and the principles which justify the existence of such museums and regulate their organizations. The second part deals with the application of these principles in three widely separated areas—India, Latin America and Sweden. Finally, actual examples are given of objects which could be usefully incorporated in science museums. This is an excellent handbook and many of the dicta are applicable to all types of museums.

The European Seismological Commission

MEETINGS of the European Seismological Commission were held at Jena during September 24–30. Representatives from twelve European countries, including the United Kingdom, attended the meetings. The meetings were first concerned with the study of reports of work presented by members of the Sub-commissions for: (*a*) Alpine explosions; (*b*) seismo-tectonic map of Europe; (*c*) seismicity of the Carpathian region; (*d*) publications. Secondly, there followed a symposium entitled "The Crust of the Earth in Europe", with data from great explosions, near-earthquakes, dispersion of surface waves, *Lg* and similar waves and microseisms. Communications were also presented on the centenaries of the births of Prof. V. Láska, by Prof. A. Zátopek, and of Prof. B. B. Galitzin, by Prof. E. F. Savarenski. The account of the work on the new seismic scales was presented by Dr. W. Sponheuer. The European Seismological Commission of the Union of Geodesy and Geophysics is indebted to the Deutsche Akademie der Wissenschaften zu Berlin for sponsoring the meetings and to colleagues at Jena under Dr. W. Sponheuer for the admirable local arrangements. The next meetings of the Commission will be held in Budapest in 1964, and the new officers are: *President*, Prof. A. Zátopek (Prague); *Vice-Presidents*, Prof. E. F. Savarenski (Moscow), Dr. E. Vesanen (Helsinki); *Secretary*, Dr. E. Peterschmitt (Strasbourg).

Christmas Lectures for Schoolboys in Chemical Engineering

The Institute of Chemical Engineers has organized two Christmas lectures for schoolboys which will be held at the Lecture Theatre of the Science Museum, South Kensington, London, S.W.7, on the afternoon of January 11. Mr. E. S. Sellars, head of the Petroleum Division of the B.P. Research Centre at Sunbury, and a vice-president of the Institution of Chemical Engineers, will speak on "Stages in the Development of the Industrial Process", and Prof. M. W. Thring, professor of fuel technology and chemical engineering in the University of Sheffield, will speak on "Some Possible Future Developments in Industry". Further information can be obtained from the General Secretary, the Institution of Chemical Engineers, 16 Belgrave Square, London, S.W.1.

The Australian Mathematical Society

The Australian Mathematical Society met in Sydney, at the University of Sydney, during August 15–17; eighty members attended. The new Council elected was as follows: *President*, Prof. E. S. Barnes; *Vice-presidents*, Profs. T. G. Room and A. L. Blakers; *Publications Secretary*, Dr. G. E. Wall; *Treasurer*, Prof. C. S. Davis; *General Secretary*, Prof. H. O. Lancaster; *Councillors for the second term*, Prof. A. Brown, Prof. R. C. T. Smith and Dr. G. Szekeres; *Councillors for the first term*, Prof. L. S. Goddard, Dr. C. F. Moppert and Prof. K. C. Westfold. A summer research institute was held at the Australian National University, Canberra, during January and February, 1962, with Prof. E. S. Barnes as director. A third meeting of the institute will be held in Canberra during January 1963, with Prof. B. H. Neumann as director. The seventh general meeting of the Society will be held at Monash University during May 21–23, 1963. Further information concerning the general meeting can be obtained from the local secretary, G. C. Smith, Department of Mathematics, Monash University, Clayton, Victoria.

The Welsh Soils Discussion Group

The following have been elected officers for the fifth session, 1962–63, of the Welsh Soils Discussion Group: *Chairman*, Dr. R. Williams, regional advisory chemist, National Agricultural Advisory Service, Trawscoed, Cardiganshire; *Secretary*, J. A. Taylor, lecturer in geography, University College of Wales, Aberystwyth; *Assistant Secretary*, Dr. C. B. Crampton, soil surveyor, National Agricultural Advisory Service, Cardiff; *Editor*, D. F. Ball, Nature Conservancy, Bangor. J. R. Hampson, Forestry Commission, North Wales Conservancy, Shrewsbury, was elected an ordinary member. The theme for the fifth session will be "Soil Moisture". A meeting of the Group will be held at Bangor on February 27, when the subject will be "The Biological Role of Soil Water". Further information can be obtained from Mr. J. A. Taylor.

The Night Sky in January

Full moon occurs on Jan. 9d. 23h. 09m. U.T. and new moon on Jan. 25d. 13h. 42m. The following conjunctions with the Moon take place: Jan. 12d. 15h., Mars 2° N.; Jan. 21d. 18h., Venus 0·1° S.; Jan. 28d. 07h., Jupiter 3° N. In addition to these conjunctions with the Moon, Venus is in conjunction with Antares on Jan. 15d. 09h., Venus being 9° N. There will be a penumbral eclipse of the Moon on January 9, visible at Greenwich; Moon enters penumbra on Jan. 9d. 21h. 04m., mid-eclipse is at 23h. 19m. and Moon leaves penumbra at Jan. 10d. 01h. 34m. There will be an annular eclipse of the Sun on January 25, invisible at Greenwich. Mercury is an evening star visible during the first part of the month low in the south-west after sunset. Venus is a morning star, rising at 4h. 15m., 4h. 25m. and 4h. 45m. on Jan. 1, 15 and 31, respectively. Its stellar magnitude is −4·2; its distance increases during the month from 47 to 69 million miles, and the visible portion of the apparent disk increases from 0·365 to 0·545. Mars rises at 19h. 40m., 18h. 30m. and 16h. 55m. on Jan. 1, 15 and 31, respectively. It is at a distance of 66 million miles on January 15, when its stellar magnitude is −0·7; conditions are now favourable for observation. Mars is in Leo, not far from Regulus. Jupiter is an evening star, setting at 21h. 15m., 20h. 35m. and 19h. 50m. at the beginning, middle and end of the month. It is in Aquarius, its stellar magnitude is −1·7 and its distance from the Earth in the middle of the month is 520 million miles. Saturn is too close to the Sun for easy observation. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Jan. 4d. 19h. 04·5m., ξ^2 Cet. (*D*); Jan. 6d. 20h. 30·7m., 63 Tau. (*D*). *D* refers to disappearance. The Quadrantid meteors are active on January 3, the radiant being near R.A. 15h. 28m., Dec. +50°. The Earth is at perihelion on January 4, its distance from the Sun being 91·4 million miles.

Announcements

Mr. H. Faulkner, director of the Telecommunication Engineering and Manufacturing Association, retires at the end of the year. He was formerly deputy engineer-in-chief of the British Post Office and has held office in the Association for nine years. Mr. Faulkner will be succeeded by Mr. R. A. Moir, until recently a director of Standard Telephones and Cables, Ltd.

The British Biophysical Society is organizing a meeting on "Nucleic Acids and Nucleoproteins" at King's College, Newcastle upon Tyne, during April 2–4. The titles of the symposia will be "Structure and Physicochemical Properties" and "Effects of Radiation". Further information can be obtained from the local secretary, Dr. G. Scholes, Chemistry Department, King's College, Newcastle upon Tyne 1.

The centenary meeting of the British Pharmaceutical Conference will be held in London during September 2–6, 1963. The closing date for the receipt of papers to be delivered at the meeting is May 1. The Conference Lecture is to be given by Dr. J. M. Barnes, head of the Toxicology Research Unit of the Medical Research Council. Further information can be obtained from the honorary local secretary, Dr. K. R. Capper, 17 Bloomsbury Square, London, W.C.1.

The British Ecological Society, which was founded in 1913, will celebrate its fiftieth jubilee with a special meeting, to be held at Queen Elizabeth College, Campden Hill Road, London, W.8, during March 8–31. The meeting will include half-day sessions on various topics, ranging from "The History of Ecology in Britain" and "Quaternary Ecology" to "Production Ecology" and "Conservation and Ecology". Further information can be obtained from P. J. Newbould, Botany Department, University College, Gower Street, London, W.C.1.

THE PRAGUE AEROSOL CONFERENCE

THE tenth anniversary of the Czechoslovak Academy of Sciences was celebrated by a conference on aerosols attended by 163 national and 56 foreign delegates. The meetings were held during October 8–13, in the Academy's castle at Liblice, near Mělník, about twenty miles north of Prague (Fig. 1).

The proceedings opened with a series of formal statements on the importance of aerosols in industry, science, agriculture, medicine and meteorology. Prof. K. Spurný, head of the Aerosol Department of the Institute of Physical Chemistry of the Academy, then outlined the development and organization of aerosol research in Czechoslovakia.

The first scientific paper was to have been given by N. Fuchs, of the Karpov Institute of Physical Chemistry, Moscow, but he and several other Russian scientists, who are well known for their work on aerosols, failed to attend although their papers were announced in the programme and no explanation of their absence was forthcoming. It is probable that this occurrence, which is common on such occasions, reflects merely the inability of the over-centralized organization of Communist countries to deal efficiently with the issue of visas and to relax its control of foreign travel.

The programme, listing more than 90 papers, will not be discussed in detail as it is intended to publish the papers and discussions in English some time in 1963; only contributions of a fundamental nature will be considered individually.

Several such papers dealt with fluid motion. Pančev (University of Sofia) used the Kolmogorov theory of isotropic turbulence to show that the root mean square of the difference between particle and air velocity is given by a formula like that for sedimentation under gravity except that g is replaced by the root mean square acceleration of an element of air which is expressible in terms of the energy of turbulent motion. The extent to which particles follow the fluctuations of air flow can thus be specified.

The formation of deposits when an aerosol flows past a step was examined theoretically by Smolik (Prague), who deduced the flow field by a combination of conformal transformation and boundary layer theories. The characteristic pattern of the deposit was shown to be decided by the re-entrainment of deposited particles.

C. N. Davies (London), in a theoretical paper, showed how the sedimentation-rate and inertia of particles, which are being sucked into a sampling orifice from air which is otherwise at rest, reduce the efficiency of sampling.

Present interest in the kinetic theory of transport phenomena in aerosols was displayed by three papers. Podzimek (Czechoslovak Geophysics Institute) calculated the Stefan flow of aerosol particles, concluding that the deposition of small aerosol particles on a water droplet, during its growth by condensation, was important in some meteorological situations; Goldsmith (Harwell), using Waldmann's theory, concluded that the atmospheric scavenging effect of molecular bombardment by condensing vapour was negligible for growing droplets which were around 10μ diameter. Two basic effects exist when aerosol particles are surrounded by diffusing vapour; a radiometer force on them, due to uneven molecular bombardment, gives rise to diffusiophoresis and a hydrodynamic drag on the particle is set up by a bulk gas flow which is necessary to preserve constant pressure in a mixture of a gas and a vapour which diffuse at unequal rates; the latter is the Stefan flow and can sometimes exceed the effect due to molecular bombardment.

These problems have been examined in great detail by Deryaghin *et al.* in Moscow. In his absence, the paper by himself and Bakanov was described by J. Pich and proved to contain a new formula for the thermal transport of particles which are large compared with the mean free path. This formula purports to explain how it is that thermal precipitators operate some 25 times better than they should, on the old theory, when sampling aerosol particles of high thermal conductivity. In the absence of the author the derivation of the formula could not be explained.

The whole subject is of interest to occupational hygiene because of this and in view of a possible importance in lung deposition of dust where the counterflow of carbon dioxide and oxygen may influence the collection of particles in the alveoli.

The abstracts of the Russian papers which were not delivered showed interest in transport problems. N. Fuchs had a theory of the discontinuities of heat, concentration and velocity, existing in a gas adjacent to an aerosol particle, which covers the difficult range when the particle size is comparable with the mean free path. Prochorov and Leonov were to have described the measurement of the minute force which exists between a pair of evaporating drops and may prevent them from coalescing. This work was also the subject of a paper which was to have been delivered by them at a discussion on the physical chemistry of aerosols held at Bristol in 1960. They were not present and were therefore unable to give a satisfactory account of the remarkable sensitivity that they claimed for their torsion balance when this was queried; the sensitivity claimed at Prague was double the Bristol value.

Another experimental paper, available only in abstract, was by Storozhilova and Deryaghin, and dealt with the lateral displacement of aerosol particles, flowing between parallel plates, due to a cross-flow of water vapour causing diffusiophoresis; confirmation of the Waldmann equation for particles small compared with the wave-length was claimed. A flow apparatus, for studying the evaporation of supercooled mists, should have been described by Dukhin, Berezhnaya and Silaev.

The subject of aerosol filtration was introduced by Pich and Binek (Institute of Physical Chemistry, Prague). Since the Brownian motion of particles increases with rise in temperature, while their stop distance, due to gas viscosity, decreases, it is clear that the minimal efficiency of a fibrous filter should shift to a larger particle size at a higher temperature; this was confirmed.

Interesting experimental work by Raduškevič and Kolganov (Moscow) was unfortunately not presented; according to the abstract this was a study of

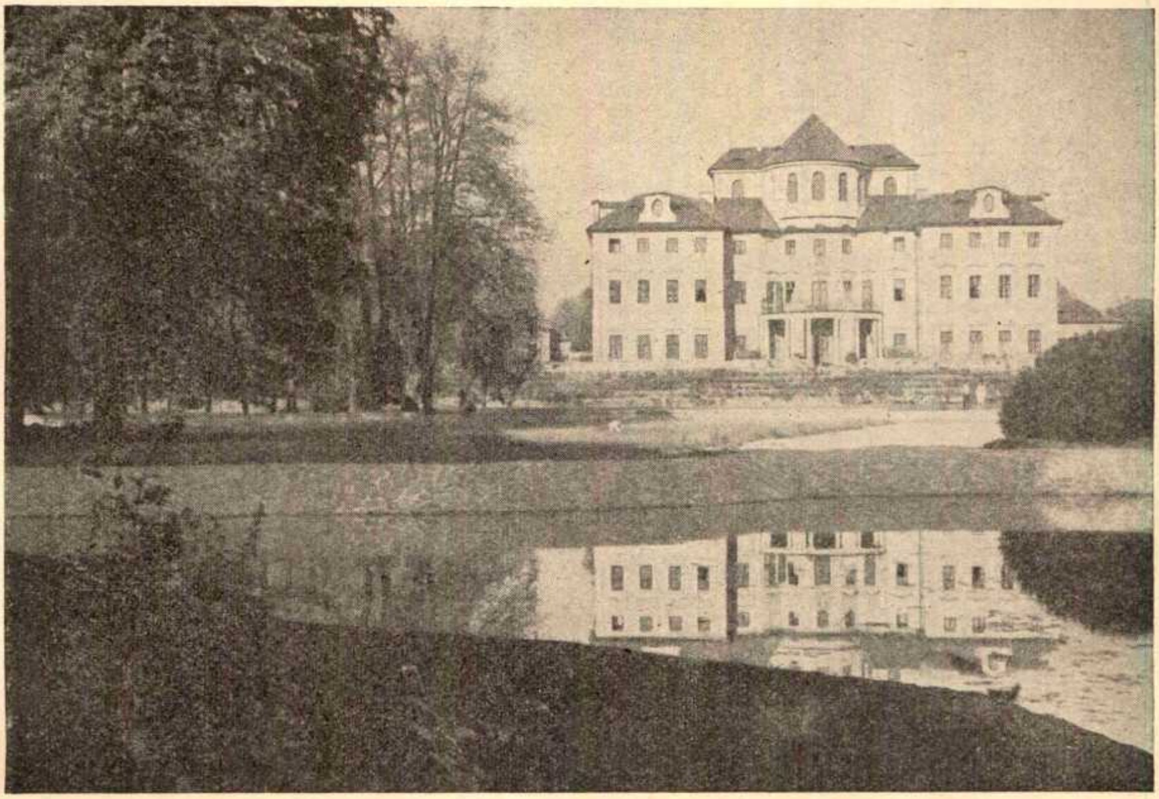

Fig. 1. The castle at Liblice which has been adapted for scientific conferences by the Czechoslovak Academy of Sciences

the deposition of particles between 0·04 and 1μ in size on individual fibres of asbestos 0·06–0·08μ thick. Spurný and Pich (Prague) had a capillary model for membrane filters which was used to explain the capture of particles.

Przyborowski (Institut für Staubforschung und radioaktive Schwebstoffe, Berlin) was concerned with the testing of filters and demonstrated the value of pre-filters in plant handling radioactive dust. Lapáček (Prague) gave an account of attempts to develop highly efficient filters capable of controlling the most dangerous radioactive substances to a level of 10^{-46} g/l. of air.

Electrostatic separation and the use of electric charges to encourage the deposition of aerosols on vegetation were subjects in the paper by Pauthenier and Ponron (Paris). The failure of electrostatic precipitators due to the build-up of an insulating layer of dust and to ionization in the deposit can now be properly accounted for. A new type of centrifugal separator was described by Binek and Pich (Prague).

A whole day was devoted to radioactive aerosols. Results of several series of fall-out measurements were given and various types of recording apparatus were described. An extremely interesting calculation of the dose absorbed, when radon decay products are inhaled was made by J. Thomas (Institute of Hygiene and Occupational Health, Prague), who made use of the best available data on lung anatomy, mucus thickness and rate of movement by ciliary action, particle deposition and the radioactive transformations, taking into account all factors which could possibly influence the dosage rate to the respiratory epithelium; his conclusions differ very much from previous ideas which have been based on global estimates rather than on an analytical approach.

The deposition of radioactivity on atmospheric particles has been examined by Lassen (Heidelberg). This process is accelerated by their electric charge to an increasing extent for particles smaller than 0·1μ. He concludes that 90–95 per cent of natural activity should be deposited on particles less than 0·5μ and 50–75 per cent on those less than 0·05μ. Experiments on the deposition of thoron decay products were described by Rüger (Institut für Staubforschung und radioaktive Schwebstoffe, Berlin).

Spendlove (Maryland, United States) directed attention to the possibility of determining the quantities of radioactive dust deposited experimentally in human subjects on the bronchial epithelium and in the alveoli by comparing the excretion-rates; extrapolated back to the time of administration these rates can be determined for gamma active particles with the subject inside a whole-body scintillation counter.

Another day was given to aerosols in meteorology. Goetz (Pasadena, United States) discussed the use of the aerosol spectrometer as an analytical tool and Mészáros (Institute of Meteorology, Budapest) noted that sodium chloride particles more than 1μ in diameter, which he had measured, could be used to identify the origin of air masses. Several speakers from the Meteorological Laboratory at Hradec Králové were concerned with atmospheric nuclei: Vrkočová and Podzimek had gelatine film methods of identifying chlorine and sulphate and membrane filter techniques for ammonium and nitrate; the latter author with Černoch surveyed flight data; Volfová and Horák found tens of thousands of Aitken nuclei per cm^3 in fogs, high concentrations which may be associated, according to Kauf (Jena), with orographical weather. Three papers dealt with meteoric dust. A gelatine film technique for measuring formaldehyde associated with aerosol particles, the first organic substance to be assessed in this way, was described by Lodge and Frank (National Center for Atmospheric Research, Colorado).

The optics of aerosol particles formed the subject of three speakers. Kubie (Institute of Physical Chemistry, Prague) gave a detailed discussion of recent developments in ultramicroscopy; Gucker, Rowell and Chiu (Indiana, United States) presented the results of Mie theory computations for spheres of dioctyl phthalate (refractive index 1·486) which are of value in determining the particle size of uniform mists from measurements of the angular intensity distributions of scattered light; the range of the parameter α (circumference of particle/wave-length) was 18·0(0·1) 23·9. Hodkinson (Safety in Mines Research Establishment, Sheffield) explained the results of his experiments on polydisperse aerosols of irregular particles for which the narrow-angle extinction coefficient can be taken as constant down to quite small sizes depending, in a simple way, on the refractive index.

Eight papers were associated with industrial aerosols and filtration and 18 with agricultural, horticultural and insecticidal applications. The final session of 11 papers dealt with medical treatment by aerosols, including an account of an ultrasonic generator which was stated to deliver into the lungs up to 1 g of material dispersed as an aerosol in 10 min. Clinical successes in this field undoubtedly require rigorous substantiation.

C. N. DAVIES

HUMAN POPULATIONS

THE three hundredth anniversary of the publication of John Graunt's *Natural and Political Observations made upon the Bills of Mortality*, the first book to be published on demography, provided the occasion for a discussion meeting organized by the Royal Society on November 15 and 16, when workers from the biological, medical and social sciences were brought together to discuss problems of common interest in the study of demography. The symposium was financially assisted by the Nuffield Foundation, which made it possible to invite a number of distinguished foreign scholars. Among those attending were Profs. R. Freedman, F. W. Notestein and E. B. Wilson from the United States, Prof. Bernardo Colombo from Italy, Mr. H. Gille from the United Nations Population Division, and Dr. J. Sutter, deputizing for M. Louis Henry of the French Institut National d'Etudes Démographiques. About fifty participants from Great Britain attended the discussion. Responsibility for the organization of the meeting was shared by Prof. D. V. Glass, Dr. P. B. Medawar and Prof. W. S. J. Morgan. The papers will afterwards be published in the *Proceedings of the Royal Society*.

The discussion began with a paper by Prof. D. V. Glass, dealing with the life and work of John Graunt. Graunt, a haberdasher by trade, was one of the earliest Fellows of the Royal Society. His election was recommended by the King himself, who particularly charged the Society "that if they found any more such tradesmen, they should be sure to admit them all, without any more ado". After sketching Graunt's life, Prof. Glass turned to an assessment of the significance of his work. He was the first to appreciate the principle of statistical regularity in demographic data; among the subjects in which he was interested were the estimation of the population of London and of Romsey, the examination of mortality differences between town and country, the case fatality of malignant fever, the investigation of infant mortality, and the introduction of the concept of the life table, though it was not until Halley wrote, some thirty years later, that the correct principles of constructing life tables were first understood. Throughout his work, Graunt was meticulous in assessing the reliability and the imperfections of his data, and his discussion of whether rickets was a new disease was a case in point. Although the generalizations he was able to make were of varying degrees of validity and universality, Graunt's work laid the foundations of demography, and of empirical work in the social sciences. His life table, though probably inaccurate at later ages, was of the right order of magnitude so far as infant and child mortality were concerned, a figure of 36 per cent dying before the age of six, being consistent with later experience of societies in a similar stage of development.

In the second paper of the session, Dr. B. Benjamin, chief statistician at the General Register Office, traced the development of the life table, and of mortality analysis in general, from Graunt through the work of Halley on deaths in the city of Breslau, to the Northampton and Carlisle tables of Price and Milne in the eighteenth and nineteenth centuries, and its full fruition in the work of William Farr, who served in the General Register Office from 1837 until 1880. Farr applied the methods of mortality analysis to the study of differentials between town and country, between healthy and unhealthy districts, and fashioned the life table into an instrument of research in the field of disease and public health. In the twentieth century came the analysis of generation mortality, following Derrick's paper, which showed a remarkable parallelism in the movement of age-specific mortality-rates among persons born in different periods.

More recently, a similar method had been applied to the mortality from lung cancer, a subject on which Mr. Beard reported in the discussion on Dr. Benjamin's paper. He found that movements in lung cancer mortality could be well described by regarding it as being made up of three components: the first depending on age, the second depending on the period of birth, which gave an indication of the proportion of smokers in the population, and a third factor depending on the intensity of smoking. This hypothesis accounted well for the different behaviour of the male and female death-rates from lung cancer.

Another contributor to the discussion, Mr. R. D. Clarke, commented on the curve of deaths, a concept first studied by Karl Pearson. He suggested that it might be fruitful to approach the analysis of mortality by regarding the maximum potential life-span of an individual as being biologically determined, and that the curve of deaths might be looked at from the point of view of determining the extent to which social and environmental factors enabled this biological potential to be realized.

The afternoon session was opened by Prof. J. N. Morris, with a comprehensive survey of recent trends in public health. He commented on public health problems in different age groups of the population, and pointed out that the declines in the infant mortality rate had been similar in different social groups. In adolescence the increased incidence of venereal disease gave cause for concern, and he showed that among younger men the number killed in motor-cycle accidents had recently experienced an alarming rise. Among the middle-aged the growing gap between the male and the female death-rate was one of the features of the present time, and coronary disease and cancer of the lung had become major public health problems. Duodenal ulcer, too, though less lethal than the former two diseases, needed investigation, but there were indications that this disease was becoming slightly less prevalent. Prof. Morris thought that there were indications that the rising trend in these diseases might not continue much further in the future. Among the elderly the problem of incapacity was becoming more serious. A figure of 10·6 per cent of males, aged 61–63, being off work for more than three months was quoted. Prof. Morris thought that it was possible that some of the survivors from previously untreatable diseases might not regain full working capacity. Among the elderly, there was considerable association between disease and air pollution—a point which was also stressed in a written contribution to the discussion by Dr. Percy Stocks. Prof. Morris concluded his paper by a plea for a closer collaboration between medicine and social statistics. In the discussion Sir Austin Bradford Hill commented on the difficulties encountered in preventive medicine to-day, as prevention of cancer of the lung, and, to some extent, of circulatory disease depended on a change in the way of life of individuals, and could not be brought about by social action, as had been the case in the reduction of mortality from infectious disease in the past.

Turning from the discussion of mortality and disease to human fertility and infertility, the next paper was contributed by Monsieur Louis Henry, who dealt with the contribution that demographers could make to the study of natural fertility. He distinguished between 'natural' and physiological fertility, the former term including certain social behaviour patterns, such as periodic prohibitions on intercourse, or length of lactation which affected fertility, but which were probably not regarded as fertility controls by individuals in these populations. Estimates of the level of natural fertility could be obtained by studying populations in undeveloped countries, or European populations living in periods before birth control had become widespread. Mr. Henry pointed to the different kinds of data that could be used for these studies, and suggested that certain researches indicated that differences in 'natural' fertility might well exist between different populations, as well as between individuals. Thus populations in the north of France seemed to be more fertile than those in the south, and this difference could be accounted for by differences in the spacing of births. Whether these in turn were due to social factors, such as longer periods of lactation, or to physiological factors, such as a longer period of post partum sterility in the southern French population, was still an open question.

The next three papers dealt with problems on the borderline of genetics and demography. Prof. L. S. Penrose dealt with genetical aspects of human infertility, Prof. K. Mather, with 'genetical demography', and Mr. J. Hajnal with concepts of random mating and the frequency of consanguineous marriages. Both Prof. Penrose and Prof. Mather stressed the difficulties of making an exact quantitative assessment of the frequency of certain genes in the population. The true frequency of lethal or sub-lethal genes was particularly difficult to determine, as normally only live births were enumerated and still-births or aborted fœtuses frequently escaped enumeration. Prof. Parkes, in a contribution to the discussion, referred to some recent work on golden hamsters, which showed that the rate of overall mortality of the fœtus within the first few days of impregnation was as high as 30 per cent. Prof. Penrose estimated that about 3 per cent of all births carried a lethal or sub-lethal gene, that a further number, probably less than 2 per cent, were viable but essentially infertile, and that between 1 and 5 per cent were viable and indirectly infertile. Prof. Mather stressed the convenience of man as a species for the study of population genetics and the importance of examining whole populations or very large samples. Penrose mentioned some conditions in which demographic behaviour patterns might influence the frequency of certain defects: thus incompatibility between mother and fœtus rarely occurred in the first-born, the incidence of mongolism was very much higher among the children of older mothers and certain other very rare genetic defects seemed to be associated with the age of the parents.

In the discussion, the problem of the negative correlation between intelligence quotient and family size was mentioned and some solutions to the apparent paradox that there was no apparent deterioration in the intelligence quotients of Scottish schoolchildren surveyed in 1932 and 1947 were put forward. The biologists tended to stress the genetic aspects of the problem: one speaker deplored the fact that in population genetics there were too many plausible explanations for the same phenomenon. Prof. Freedman said that in recent studies in the United States, provided social class was held constant, no correlation between intelligence and size of family was found. A suggestion was made in the discussion that more information of a genetic nature might be obtained in the population census, and that the Royal Society might well put pressure on the Registrar General to include questions on this topic in future censuses.

Mr. Hajnal's paper was concerned with a slightly different topic: the assessment of the frequency of cousin marriages in large populations. He showed that it was necessary to distinguish between different kinds of cousin marriage, and had constructed models showing the theoretical frequency of different kinds of cousin marriage under certain general assumptions. The theoretical frequencies were compared with some large-scale surveys and considerable agreement between theory and observation was shown.

Turning back to human demography proper, Prof. E. Grebenik and Miss G. Rowntree presented a paper dealing with the fall in the age at marriage in the population of Great Britain. Results from a recent survey showed that this fall was spread over all social groups of the population: though there seemed to be some slight indications that middle-class girls experienced a higher fall in marriage ages than others. The removal of marriages in which the bride was pregnant at marriage reduced the differentials somewhat; but left the principal conclusions unchanged.

Sir Aubrey Lewis dealt with demographic aspects of mental disorder and surveyed the statistics of different kinds of mental illness, stressing the increase in the rate for elderly persons. In the discussion, stress was laid on the considerable variation in the geographical incidence of various forms of mental disorder, and Miss E. Brooke, from the General Register Office, surveyed some of the results of the Mental Health Survey undertaken by the Registrar General, and commented on the influence of social environment on the incidence of mental disease.

Prof. R. Freedman, of Michigan University, reported on norms for family size in underdeveloped countries. He reminded the audience that all societies regarded the number of children born to a couple as important both individually and socially, and that even in undeveloped societies potential measures of control were available. Surveys asking for the ideal number of children obtained answers which tended to cluster around modal values without great dispersion. Large numbers of children were not regarded as desirable in many undeveloped societies. He then turned to the problem of changing attitudes and said that one of the most important factors in spreading smaller norms was the enlargement of the social unit within which communication normally took place. The role of education and literacy, in his view, was much more important than had hitherto been recognized.

The symposium concluded with a closing statement by Prof. F. W. Notestein. He stressed the importance of demographic research, and deplored the inadequacy of funds available for its prosecution, both on the social and on the physiological side. More money was spent on the investigation of certain very rare and esoteric diseases than on the physiology of reproduction. While the reduction of fertility in countries which are at present growing rapidly was extremely important, he thought it vital that allocations of economic aid should not be made dependent on acceptance of birth control, as had been suggested in some quarters. The desire to limit family size would have to grow within these societies and any attempt to impose it by force or by certain economic sanctions could only lead to anti-Western political feeling being associated with opposition to reduced fertility. Economic development was a necessary condition before population growth could be controlled. He felt that the symposium had served a useful purpose in bringing together scholars from different disciplines, and in showing how much each of them had to contribute to the study of human populations. The Royal Society was to be congratulated on arranging this meeting and he hoped that it would be followed by others, so that natural and social scientists would be able to collaborate in the broader study of mankind and its problems.

ADAPTIVE TEACHING MACHINES

An adaptive teaching machine is a machine that modifies its training programme to suit the student's individual requirements. Like the real-life teacher, it 'learns' about the student's difficulties and takes steps to remedy those misunderstandings which the student is unable to overcome by his own efforts. To achieve this objective, the adaptive teaching machine presents a sequence of instructional items on some suitably automated display, and a sequence of test items for establishing whether or not the instruction has been understood. Test items usually consist of questions to which the student must respond by pressing, within a given time allowance, an appropriate button or key. The working of the machine and the uses to which it may be put have been described by B. N. Lewis of Birkbeck College, London*.

By noting on internal registers the speed and accuracy with which particular items are handled, the machine can build and maintain an up-to-the-moment account of the student's strengths and weaknesses. Computations performed on these registers then enable the training programmes to be adjusted in ways that seem best suited to the student's special idiosyncrasies. In the simplest case, each register is concerned with detecting the presence of a distinct kind of misunderstanding or difficulty. Thus, if prior investigations have shown that a particular skill or subject-matter is susceptible to five basic misunderstandings (in the sense that five different 'dimensions of confusion' habitually operate to frustrate the learning process), the machine will need at least five error registers on which to evaluate the student's mistakes.

If these registers are called *A*, *B*, *C*, *D* and *E*, and the student's first mistake indicates (according to some pre-established criterion), the possibility of *A*, *B* or *E*-type misunderstanding, and if the second mistake points to misunderstanding *B* or *D*, then the two mistakes collectively suggest that misunderstanding *B* is predominant. This information enables the machine to switch to a 'correctional programme' which explicitly concentrates on the removal of *B*, while at the same time continuing to secure evidence about the other possible misunderstandings.

Alternatively, the machine could continue to accumulate evidence over a much longer sequence of tests before taking corrective action. In either case the machine must contain an overall control mechanism that scans the states of its errors registers, performs the necessary computations, and adjusts its programme according to some built-in decision rule(s). These adjustments (and the decision rules on which they are based) conform to a well-designed plan and are in no way haphazard. Without exception, they are intended to keep the level of tuition within the rather narrow limits that the student himself determines. It is, therefore, essential that instruction should be pitched at just the right level of difficulty and should be continuously adjusted as a function of the student's performance. The most direct way of adjusting difficulty is to vary the standard of the instructional items (by omitting some or modifying others), and to make correlative changes in the content of test items. But it is often more convenient to hold the instructional and test items fairly constant and to operate, on a separate display if necessary, a variable supply of supplementary information and hints. In addition, it is useful to impose limits on the time allowed for assimilating instructions and responding to test questions. The time limits can then be differentially adjusted so that longer time is allowed in respect of items that the subject is likely (according to the machine's computations) to find difficult.

---

* *The Science Teacher*, 6, No. 1 (October 1962).

These two gambits have been successfully used in several commercial teaching machines of which the best known is the *SAKI* (Solatron Automatic Keyboard Instructor) device. This was pioneered by Gordon Pask for training operators on the 12-key 'Hollerith' card punch. Briefly, the system consists of a display unit that gives instructions and prompts, a keyboard which the trainee must operate (without looking at the keys), and an adaptive computer which 'senses' the characteristics of the student and adjusts the training programme to suit his needs. The display unit consists of a back-lighted exercise card (containing four lines of 24 figures) and an array of 12 lights laid out in the same spatial pattern as the 12 keys on the keyboard. Since some combinations of figures are harder to punch than others, the exercise cards are changeable and are graded with respect to difficulty.

The figures on the exercise card are illuminated one at a time (moving from left to right) and, for each figure that appears, a corresponding light shines in the 12-light array to indicate the position of the key on the real keyboard. The trainee's task is to press the appropriate key within a given allowance. If he fails to do so, the figure is automatically replaced by the next figure to the right, and the trainee is recorded as having made a mistake. During the early stages of learning the figures move on rather slowly. However, as the trainee gains in speed and accuracy the waiting times become shorter, and the prompting lights (in the 12-light array) diminish in intensity. But this is done differentially, so that the machine continues to wait longer and to give prompts on those keys which persist in giving difficulty. Furthermore, it will slow down and restore prompts in respect of any key on which the trainee has a sudden relapse. Whereas the simpler teaching machines take corrective action on the basis of just one response, *SAKI* adjusts its programme in accordance with an integrated performance measure (based on speed and accuracy) assured over a whole series of responses. *SAKI* also 'paces' the student by adjusting difficulty and time pressure so that he is always working near the limit of his ability.

This machine uses a technique that tends to minimize the amount of useful information gained about the student. For if the student were to be given easy problems that almost everyone could solve, little would be learned about him. Conversely, little is learned by loading him with problems which are beyond his capacity. An optimal 'in-between' strategy is to start with easy problems and to step up their difficulty. But this means the student is most likely to reveal his incipient weaknesses without, at the same time, wanting to withdraw from the situation. By keeping the student around the threshold of his ability, his attention tends to be completely absorbed by the instructional material presented, and this renders him controllable for teaching purposes. As a further refinement the teaching machine may conceal the fact that it has detected a weakness in the student; in this way it can continue to probe for information without losing the student's goodwill.

The teaching principles embodied in *SAKI* are entirely general. Adaptive machines have been built to instruct such diverse skills as typing, fault-finding and equipment maintenance, radar training, pattern recognition, and inductive and deductive reasoning. In every case the same dynamic relationship is established between the student and machine, so that the student is spurred on to greater and greater efficiency under optimally congenial conditions. There are theoretical reasons for supposing that no teaching method could be better than this.

THE COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION (AUSTRALIA)

THE fourteenth annual report of the Commonwealth Scientific and Industrial Research Organization (Australia)*, covering the year ended June 30, 1962, besides the general review and brief survey of progress in research, includes lists of papers published during the year and details of membership of the Advisory Council, State Committees and staff. Of total expenditure of £12,089,389, £1,122,354 was on capital works, and of £10,967,035 spent on investigations, £174,814 went to the Commonwealth Agricultural Bureaux and other outside bodies. Expenditure on the Animal Research Laboratories was £1,190,120; on plant research, £994,727; entomology, £434,183; soils research, £360,048; food preservation, £390,294; forest products research, £426,306; chemical research laboratories, £981,747; the National Standards Laboratory, £836,017; fisheries and oceanography, £257,412; building research, £208,046; radiophysics, £429,664; wool research, £711,331; land research and regional survey, £364,929; dairy research, £165,698; tribophysics, £125,988; fuel research, £299,203; and wildlife survey, £187,254. During the year, 35 junior and 41 senior postgraduate studentships were awarded and 10 overseas studentships. The 210-ft. radio-telescope for the Division of Radiophysics was officially commissioned on October 31, 1961.

Among the legumes and grasses of value to the grass industry as a result of the work of the Tropical Pastures Division are *Lotononis bainesii*, *Siratro* and *Nunbank* buffel grass, while 100 per cent prevention of *Phalaris* staggers was obtained by administration of heavy cobalt pellets along with steel grinders to cattle grazing on *Phalaris tuberosa*. A method of soil analysis has been developed to give a direct assessment of the phosphate fertilizer requirements of wheat for the most economic return, and field experiments indicate that the average rate of application of superphosphate in the southern wheat belt of New South Wales could be increased to give returns of

£2–3 per acre. A broad-scale field survey of the Tipperary region in the Northern Territory was completed during the year, and inoculation of pelleted seed with very high numbers of nodule bacteria by a multi-step process has produced up to 100 per cent nodulation of subterranean and crimson clovers sown on skeletal hill soils where the standard commercial inoculation is without effect. A technique has been developed permitting separation of composite particles of silica from a plant without damaging the structure or altering the composition of the particles; detailed studies of the silica from the vegetative and reproductive parts of the mature oat have revealed that the walls of all types of epidermal cells except cork cells are impregnated with silica.

Studies with radioactive phosphorus have shown that roots of *Pinus radiata* infected with mycorrhizal fungi take up larger amounts of nutrient and suggest that particularly efficient fungi can be selected for inoculating forestry nurseries. Evidence has been obtained that the cellular organelles (mitochondria) associated with the production of adenosine triphosphate in plant tissues of fruits become heavily labelled by the methyl group of methionine, mostly in the lipid fraction, and, in particular, plant sterols and ubiquinone have been isolated and found to be radioactive. The natural enzymatic formation of iron-porphyrin complexes is being investigated, and the structure of the anti-fungal compound, pisatin, isolated from infected peas, has been established as 3-hydroxypterocarpin.

As little as 0·01 per cent of decontaminating proteins have been detected in the protein hormones that control wool growth by zone electrophoresis on starch gel, and the breakdown of metabolic efficiency incurred by vitamin-B_{12} deficiency in sheep has been located in the chemical transformation through which propionic acid is launched into the energy-producing cycle, that is, in the isomeric conversion of the intermediate methylmalonic acid to succinic acid. An investigation of the pyrrolizidone alkaloids occurring in plants indicates that those causing chronic or acute liver damage when eaten by animals have similarities in the structure of their molecules and that their effects on the cell nuclei resemble the effects of the so-called biological alkylating agents. An investigation of the flight behaviour of the Australian plague locust early in 1962 indicated that the occurrence of numerous flying swarms in the 'outbreak areas' is not necessarily a prelude to a widespread outbreak.

A laboratory has been established at Canberra, where the alarm and distress signals of several species of birds have been recorded and prepared for analysis, and where aggressive, territorial, food finding, mating and other calls are being studied in relation to the behaviour and social organization of birds. An infra-red design of a single-effect solar still with a plastic base, producing about 10 gal. of distilled water on a clear summer day, at an estimated cost of £1 per 1,000 gal., is undergoing tests and a prototype for use in isolated areas is being built. The illumination of pedestrian crossings by floodlighting the pedestrians from the directions of the approaching traffic streams has been successfully tested in two experimental installations. Four protein preparations have now been extracted from wool fibre; the two with a high content of sulphur have much smaller molecules than the two with a low content of sulphur and are basic in nature in the original fibre, whereas the low-sulphur proteins are acidic. Ultra-violet radiation in sunlight splits the disulphide bonds of cystine, and chemical investigations of pure cystine suggest that, in presence of air, it is the bond between the carbon and sulphur atoms that is split in neutral and alkaline solutions, whereas in acid solutions the bond between the two sulphur atoms is split.

By spray drying an emulsion of butter fat in a solution of sodium caseinate and non-fat milk solids a new dairy product, powdered butter, has been produced, containing 80 per cent of fat with 15 per cent of milk protein and some mineral salts, which is more convenient than normal butter for use in cakes, frying batter and ice-cream. A long-term investigation is in progress of the physical factors important in bulk wheat storage, particularly heat and moisture transfers within the bulk. A new humidity-sensitive element, consisting essentially of a thin layer of selenium dioxide, the electrical resistance of which responds to changes in the humidity of the surrounding atmosphere, has been developed with rapid response and good accuracy even at more than 90 per cent relative humidity and near the freezing point. Completion of the first survey of the distribution of ozone in the southern hemisphere has shown that the distribution differs significantly from that in the northern hemisphere. Mathematical methods for removing the effect of the spread of energy and greatly reducing the random scatter in ionization investigations have been devised by utilizing certain redundancies in the measured data. An instrument has been devised which measures simultaneously the atmospheric distortion in measurements of the total light from a star, its position and its image.

UNIVERSITY DEVELOPMENT IN INDIA

THE Statistical Report, 1961–62, on *University Development in India**, prepared by the Statistics Section of the University Grants Commission, New Delhi, is based on returns received from the 53 universities recognized in July 1962; of these 15 are unitary, 2 federal and 36 affiliating, while there are 5 other institutions, including the Indian Agricultural Research Institute, New Delhi, and the Indian Institute of Science, Bangalore, deemed to be universities under the University Grants Commission Act of 1956. The number of teaching departments was 904, including 233 in science, 80 in medicine, 33 in engineering and 17 in technology, and the total number of students enrolled was 980,380, of whom 841,580 were in the 1,676 affiliated colleges and 138,800 in the teaching departments: there were also 169,627 women students; these totals represent increases of 13 per cent and 12 per cent, respectively, on the number of students in 1960–61. The Universities of Agra, Bombay, Calcutta, Kerale, Madras and the Punjab together account for 40·1 per cent of the total compared with 41·8 per cent in 1960–61, and there are now 6 universities instead of 2 with less than 1,000 students.

---

* *University Development in India*: A Statistical Report, 1961–62. Pp. vii + 76. (New Delhi: University Grants Commission, 1962.) Rs. 3.50 nP.; 5s.

The total teaching staff was 54,853, together with 8,200 tutors and demonstrators, giving a staff–student ratio of 1 : 15·5; slight improvement is noted at Agra, Calcutta and the Punjab, but at Madras and Kerale the ratio has worsened. Students residing in halls of residence numbered 178,423, or 18·2 per cent compared with 17·6 per cent the previous year. Some 72,859 students were engaged in postgraduate/research work compared with 63,000 the previous year. Of the postgraduate students 14,511 were in science, with a further 1,876 engaged in research, but for engineering and technology the corresponding figures were only 418 and 29 and 243 and 17, respectively, and in medicine, 1,841 and 46. Besides an analysis of enrolment trends generally the report reviews the estimates for the Third Year Plan in comparison with the Second Year Plan, which sets a target of 1,300,000 students in 58 universities in 1965–66 and is expected to provide 21,000 postgraduates in science, 100,000 engineers and technologists, and some 32,000 in agriculture and allied sciences. Expenditure on research is estimated at 130,000 crores of rupees, compared with 7,200 under the Second Plan.

DEMAGNETIZING FIELDS OF INHOMOGENEOUS INDUCED MAGNETIZATION

By Dr. ANDREAS VOGEL

Institute of Geodesy, Geophysical Laboratory, Uppsala-Hallby

THE induced magnetization of bodies with constant susceptibility and homogeneous magnetization is described by the following equation:

$$J_e = J_0 - \varkappa N J_e \qquad (1)$$

when J_e = effective magnetization; J_0 = primary magnetization; $\varkappa$ = susceptibility; N = demagnetization factor.

Based on the effect of free magnetic poles on the surface of magnetized bodies N has only been calcul-

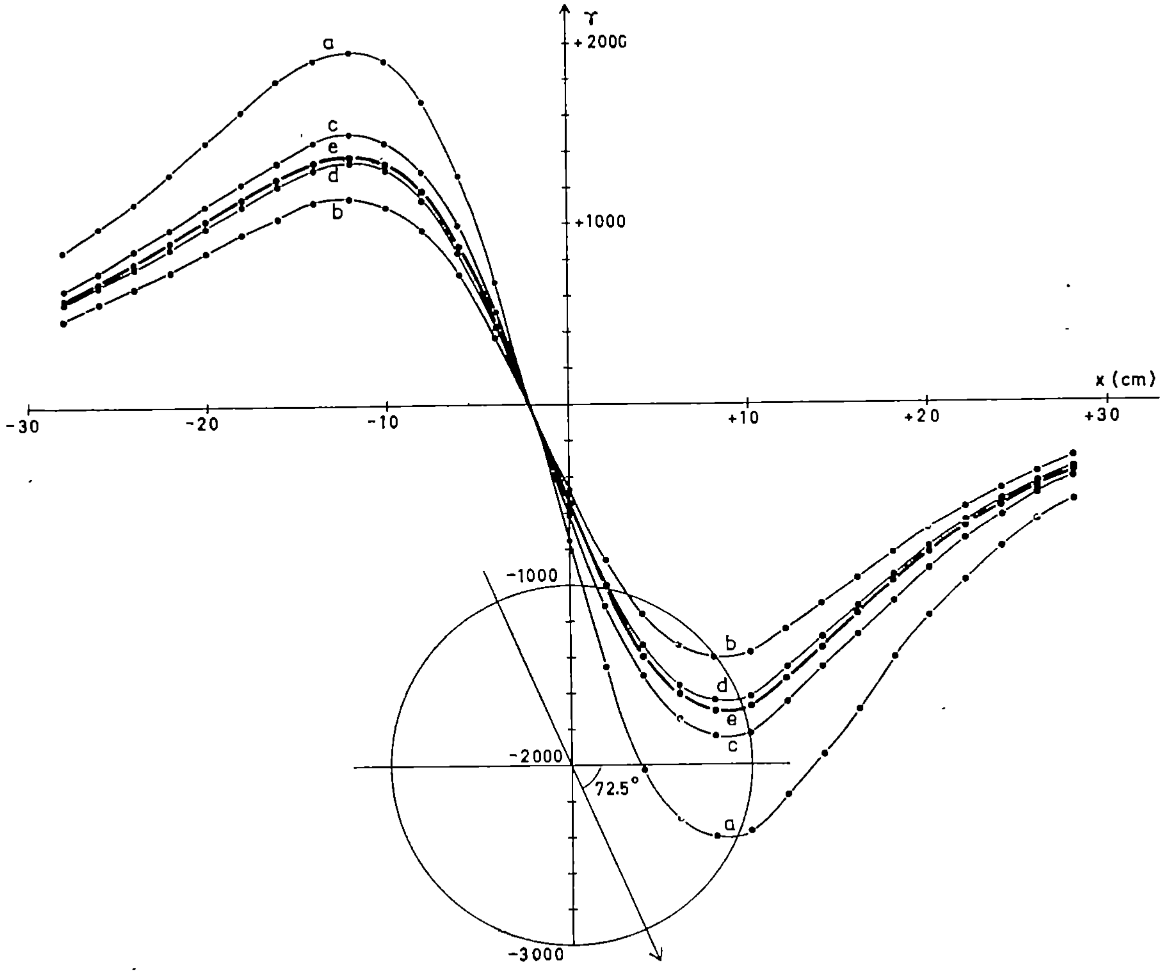

Fig. 1

ated for special bodies. It has been experimentally proved, however, that this formula can only be applied to bodies of second degree surface lying in a homogeneous magnetizing field.

In this case the demagnetizing field is opposite to the definite magnetization so it can be replaced by the factor N. In the case of inhomogeneous magnetization the demagnetization has to be expressed by a vector.

Here it will be shown in which way the definitive magnetization for any bodies can be established. This method is based on iterative calculation of magnetizing fields inside the body. The field beyond a body with the magnetization $J_0 = H_0\varkappa$, where J_0 is the primary magnetization, H_0 the magnetizing field and $\varkappa$ the susceptibility of the body, can be derived from the potential:

$$V = \int \left(J_{0x}\frac{\partial}{\partial_x} + J_{0y}\frac{\partial}{\partial_y} + J_{0z}\frac{\partial}{\partial_z} \right)\frac{1}{r}\,dx\,dy\,dz \qquad (2)$$

J_{0x}, J_{0y}, J_{0z} are the components of J_0 and r is the distance from the element $dx\,dy\,dz$.

This function, when applied inside the body, gives after derivation the inner field H_1 due to the primary magnetization J_0. The field H_1 causes a magnetization J_1. The field which comes from J_1 by integration with equation (2) is H_2 and the magnetization due to H_2 is J_2, etc. The effective magnetization will be the sum of the magnetization fields:

$$J_e = \varkappa(H_0 + H_1 + H_2 + \ldots\ldots) \qquad (3)$$

This method of iterative calculation of magnetization fields can be illustrated by taking the simple case of a homogeneous magnetized sphere. The susceptibility of the sphere may be $\varkappa$ and the magnetizing field H_0. The inner field due to this magnetization is $-\left(\frac{4}{3}\pi\varkappa H_0\right)$, the magnetization by this field is $\varkappa\left(\frac{4}{3}\pi\varkappa H_0\right)$. This magnetization gives an inner field with the intensity $+\left(\frac{4}{3}\pi\varkappa\right)^2 H_0$ and the magnetization $+\varkappa\left(\frac{4}{3}\pi\varkappa\right)^2 H_0$, etc.

The sum of these magnetizations gives the effective magnetization:

$$J_e = \varkappa\left[H_0 - \frac{4}{3}\pi\varkappa H_0 + \left(\frac{4}{3}\pi\varkappa\right)^2 H_0 - \ldots\ldots\right] \qquad (4)$$

If J_e is replaced by $H_0\varkappa_e$, where $\varkappa_e$ is the effective susceptibility, we get after division by H_0:

$$\varkappa_e = \varkappa\left[1 - \frac{4}{3}\pi\varkappa + \left(\frac{4}{3}\pi\varkappa\right)^2 - \ldots\ldots\right] \qquad (5)$$

Formula (1) can be written:

$$\varkappa_e = \frac{\varkappa}{(1 + N\varkappa)} \qquad (6)$$

Or if we replace N by the demagnetization factor of the sphere $\frac{4}{3}\pi$:

$$\varkappa_e = \frac{\varkappa}{\left(1 + \frac{4}{3}\pi\varkappa\right)} \qquad (7)$$

For the case of a sphere the iterative field computation, equation (5), gives a formula which is mathematically a series of equation (7). It can easily be shown that for homogeneously magnetized

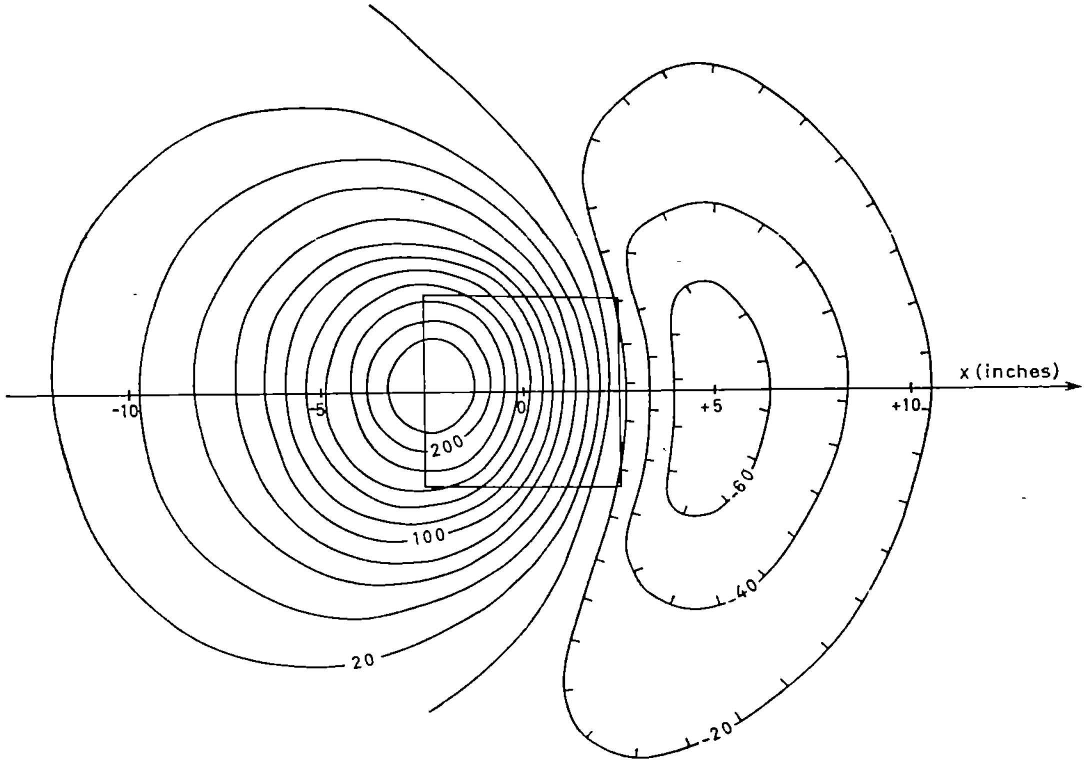

Fig. 2

bodies we always get identical results with equation (6), which has been proved by experiment.

Equation (4) can be written generally for all homogeneously magnetized bodies:

$$J_e = \varkappa[H_0 - N\varkappa H_0 + (N\varkappa^2)H_0 - \ldots\ldots] \quad (8)$$

The example of a sphere with the susceptibility $\varkappa = 0{\cdot}1$ in a field with intensity $H_{0x} = 15{,}000\gamma$ and $H_{0z} = 47{,}500\gamma$ demonstrates practically the way in which the sum of magnetizing fields converges towards the definite magnetization.

Fig. 1 represents the relative horizontal intensity of this sphere with radius $r = 10$ cm in a horizontal profile at a distance of 20 cm from the centre of the sphere.

The curve *a* is the horizontal intensity for the effective magnetization derived from equation (1); the curve *b* is based on the primary magnetization $J_0 = H_0\varkappa$ without considering demagnetization. The curve *c* is based on the magnetization $(H_0 + H_1)\varkappa$, curve *d* on $(H_0 + H_1 + H_2)\varkappa$ and *e* on $(H_0 + H_1 + H_2 + H_3)\varkappa$.

Now let us proceed to a body which is not magnetized homogeneously in a homogeneous field.

Hendersson and Zietz[2] have measured in the laboratory the total field of a horizontal plate with the dimensions 5 × 5 × 0·5 in. in a plane 5 in. above the plate. The magnetizing field was $H = 53{,}400\gamma$, the inclination 60° and the susceptibility of the plate $\varkappa = 0{\cdot}066$. The results are shown in Fig. 2. From these values in the plane the mid-section in north–south direction was taken and the relative total intensity for the same profile was calculated by me.

Before starting the calculation of inner inhomogeneous fields with computers the body has to be divided into elements. The accuracy in the calculation of magnetization increases when the elements are diminished. For the centre of each element the field vector due to the magnetization of all elements of the body has to be calculated. The field calculations of different order were made in 32 points in the plate's interior. In order to avoid too long computing time, when making this first trial, mean values of the components of H from all points were taken starting with H_1. The magnetization from these mean values of H was always taken for the field calculations, which were continued to that order which gave less than 1/100 of the primary field.

In this way the following magnetizing field components were calculated:

$H_{0x} = +\,0{\cdot}26700\gamma$; $H_{1x} = -\,0{\cdot}01650\gamma$.

$H_{0z} = -\,0{\cdot}46250\gamma$; $H_{1z} = +\,0{\cdot}20572\gamma$; $H_{2z} = -\,0{\cdot}08879\gamma$; $H_{3z} = +\,0{\cdot}03836\gamma$; $H_{4z} = -\,0{\cdot}01657\gamma$; $H_{5z} = +\,0{\cdot}00716\gamma$; $H_{6z} = -\,0{\cdot}00309\gamma$.

$\Sigma H_x = +\,0{\cdot}25050\gamma$; $\Sigma H_z = -\,0{\cdot}31971\gamma$.

The effective magnetization is $\varkappa\Sigma H$:

$$J_x = 0{\cdot}0165 \text{ c.g.s.}; \; J_z = 0{\cdot}0211 \text{ c.g.s.}$$

Integration over the whole plate with the above magnetization gives the outer field. For this field in Fig. 3, curve *c* demonstrates the relative total intensity on the same profile as that which has been taken from the measurements of Hendersson and Zietz (curve *b* is the same profile without regarding the demagnetization).

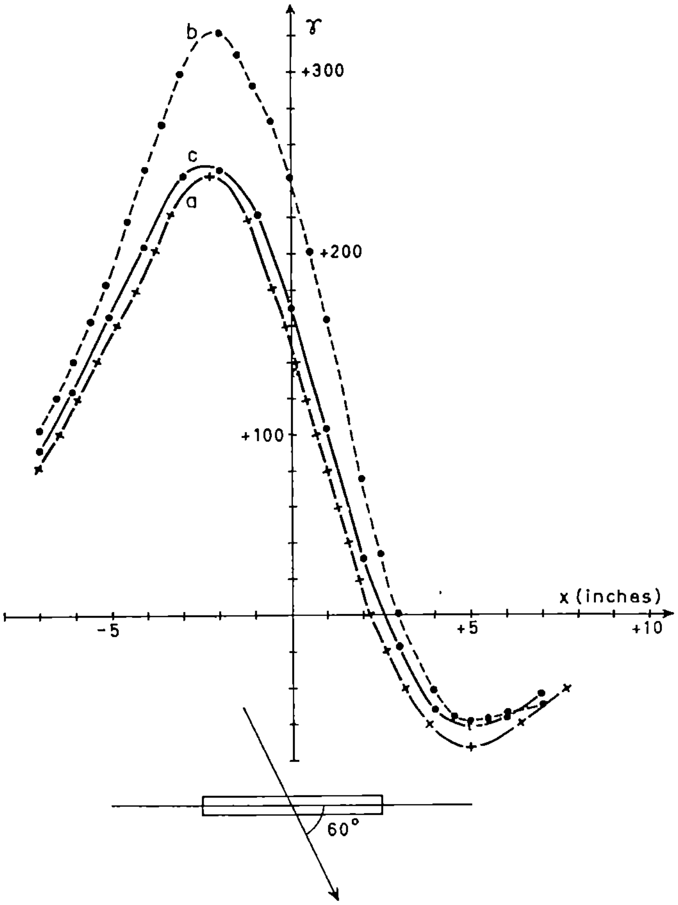

Fig. 3

The graph *c* is, with small deviations, parallel to *a*, the measurements of Hendersson and Zietz. The parallel displacement in vertical direction of about 12γ can only be explained by the fact that the measured total intensity has been reduced to a normal field which is some gammas too high.

When shifting the measured graph by + 12γ the deviation of the two graphs will be less than 2 per cent of the whole amplitude. This error comes mainly from approximation: the number of the points in which the field calculations had been made inside the body is not infinite and in the process of successive calculation the mean value of magnetization has been taken when proceeding to the next order field.

In comparison with the earlier used methods for calculation of demagnetization, this iterative calculation of inner fields is not restricted to special cases or bodies. The theory which has been developed here makes it possible to calculate the demagnetization, that is, the effective magnetization of all bodies however complicated geometrically, when magnetized in a field with given distribution.

I thank Dr. K. Arle from the Swedish Board of Computing Machinery, Stockholm, for her assistance in the programming.

AURAL RECOGNITION TIME FOR MULTI-DIMENSIONAL SIGNALS

By DR. P. W. NYE
National Physical Laboratory, Teddington, Middlesex

IT is now well known from the work of Pollack[1] Pollack and Ficks[2], Garner[3], Hayes[4], Eriksen[5], and others that the information per symbol transmitted to a subject can be increased if a multi-dimensional display is utilized. In the majority of these experiments the subjects carried out the discriminations by a check list procedure and no time limits were imposed. It was possible, therefore, that the higher information transfer could be achieved at the expense of time by storing the signal in the immediate memory, or S system, and carrying out serial discriminations on dimensions in the P system (Broadbent[6]). However, the experiment described here indicates that, provided sufficient practice of the association between a multi-dimensional signal and its response is received, the discriminations of these signals can be made at least as rapidly as well as more accurately than corresponding discriminations of signals containing fewer dimensions.

Two codes were constructed (Fig. 1) using the dimensions of frequency, intensity, modulation, noise content and direction, being similar to those used by some earlier workers[2,7]. The intensity-levels used in the $5D$ code were 0 db. and -12 db., and those for the $3D$ code were 0 db., -10 db. and -20 db.; the maximum intensity-level, zero decibels, was adjusted arbitrarily by each subject. All signals were tape-recorded giving a noise-level at about -40 db. relative to the maximum possible signal intensity. The noise dimension was achieved by the addition of a separate noise source raising the background noise level to -12 db. Double side-band modulation giving either a square or sinusoidal envelope formed two states of the modulation dimension while the third was an unmodulated pure wave-form.

Fig. 1. Structure of the two codes. 'Direction' indicates that sound originated from left or right earphone

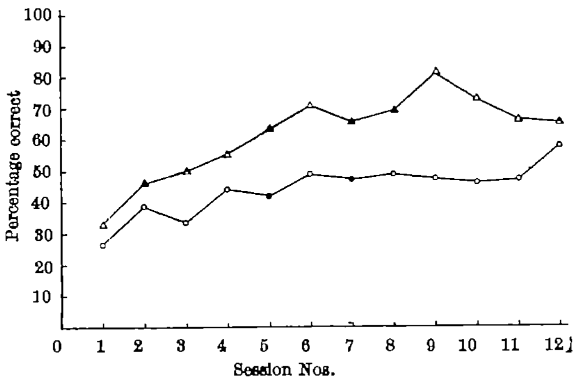

Fig. 2. Learning curves for the two groups of subjects using the full alphabet. ○, $3D$; △, $5D$

Two groups of four subjects, aged 18–25, were recruited and matched for academic ability. Each group began a course of training at letter recognition using one of the two codes. The training-method involved the division of the alphabet into three approximately equal sections which were learnt separately, the transition to the next being made when the slowest member of the two groups had reached the 60 per cent correct level. When each section had been studied in this way the training on the complete alphabet was begun. The average performance of the two groups is shown in Fig. 2 for the nine sessions immediately prior to the final testing and also of the three final test sessions. Each session lasted for 15–20 min and consisted of: (a) earphone balance and adjustment; (b) a short refresher course; (c) practice under test conditions; (d) test recognition of forty symbols. A total of 5 h of subject participation was accumulated from regular sessions during a period of nearly two months. The signals were always 0·6 sec in length and were followed by a 3-sec interval during which the subject made his verbal response. The time was measured from the beginning of the signal to the beginning of the response in each case for a total of 120 symbols selected randomly from the full alphabet. All these

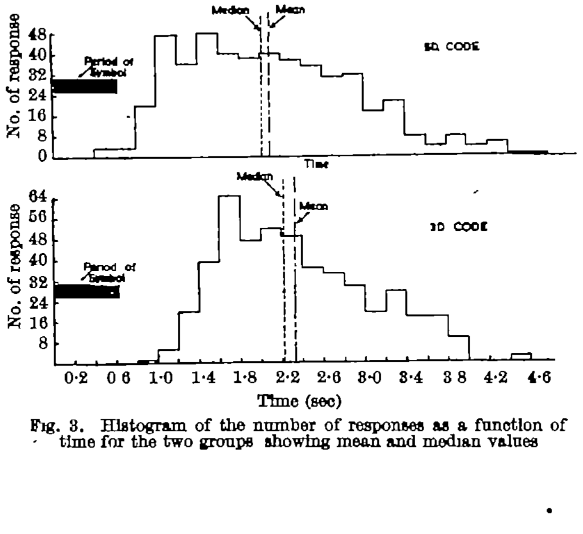

Fig. 3. Histogram of the number of responses as a function of time for the two groups showing mean and median values

Table 1

Group	Subject	Variance	Mean	Group variance	Group mean	't'
3*D*	K. F.	0·84	2·24	0·48	2·34	
	A. C.	0·25	1·95			
	M. W.	0·39	2·53			
	P. P.	0·61	2·63			4·9
5*D*	R. C.-H.	0·18	1·32	0·64	2·10	
	J. K.	0·22	2·16			
	R. H.	0·57	2·72			
	K. H.	0·61	2·18			

Table 2

Group	Dimensions	Input information	Transmitted information
3*D*	Frequency	1·58 bits	0·74 bits
	Intensity	1·58 bits	0·43 bits
	Modulation	1·58 bits	0·81 bits
5*D*	Frequency	1·00 bits	0·47 bits
	Intensity	1·00 bits	0·55 bits
	Modulation	1·00 bits	0·55 bits
	Noise	0·93 bits	0·65 bits
	Direction	0·97 bits	0·61 bits

results have been histogrammed in Fig. 3. The distributions are not significantly changed if only the correct responses are considered. The complete set of response times were therefore pooled for each subject and group and the mean and variances calculated in Table 1.

An information analysis[8] of the three test sessions revealed an average transmission of 3·30 bits/symbol from a possible 4·57 bits/symbol for the 5*D* code compared with 2·60 bits/symbol from a possible 4·62 bits/symbol for the 3*D* code. The information contributed by individual dimensions is shown in Table 2.

The average response time to the 5*D* code was shorter by 0·24 sec than the corresponding time for the 3*D* code, this difference being significant to better than the 0·001 level of probability. However, an insufficient number of subjects were available to permit the elimination of individual variations from the results and hence it is not possible to show directly that the difference between the performance of the two groups did not arise from individual variations. Nevertheless, there is no indication that the 5*D* code gives the slower performance expected from a 'check list' discrimination procedure.

The five dimensional symbols were also identified more accurately. The plateau in the learning curve of Fig. 2 for the 5*D* code occurs at 70 per cent while the corresponding plateau for the 3*D* code is at 49 per cent.

Hick's[9] results indicate that in a signal-response situation, speed and accuracy can be exchanged, and if, therefore, the amount of information transmitted by the two codes were made equal, response times to the 5*D* code could be decreased by an amount proportional to the difference in information transmitted by the two codes (that is, α (3·30–2·60) bits). This would result in a further increase of the difference in response time between the two codes.

Pollack and Ficks[2] and Miller[10] have discussed the significance of multi-dimensional signalling for the study of language structure. Speech can be regarded as a multi-dimensional display medium, although the dimensions of speech are certainly not those of Pollack and Ficks's experiments and are more likely to resemble the discriminant features of Cherry, Halle and Jakobson[11]. It has previously been uncertain, however, whether the multi-dimensional structure of speech is the significant factor on which the speed of recognition depends. The present results indicate a confirmation of the role of dimensionality in speech and suggest the conclusion that when rapid discriminations are demanded it is the capacity of the discrimination or *P* system that is ultimately dependent on the dimensionality of the input signals.

This work is part of a research programme of the St. Dunstans Scientific Committee and is published with its permission. I thank the Director of the National Physical Laboratory and the Superintendent of Autonomics Division for making available facilities for this work. I also thank Mr. R. Rengger for assistance in the experimental work.

TERTIARY MAMMALIAN FAUNAS AND SEDIMENTS IN KARAMOJA AND KAVIRONDO, EAST AFRICA

By Dr. W. W. BISHOP* and F. WHYTE

Department of Geology, University of Glasgow

IN August and September 1961 we investigated a series of fossiliferous strata occurring at or near the base of deposits associated with several Tertiary volcanic centres in East Africa. The areas visited in Uganda were south-west of the dissected volcanic cone of Napak (34° 17′ E., 2° 5′ N.), and to the north of Moroto Mountain (34° 45′ E., 2° 32′ N.). In Kenya, the principal localities were at Songhor (35° 13′ E., 0° 3′ S.), Koru (35° 16′ E., 0° 11′ S.) and Fort Ternan (35° 20′ E., 0° 14′ S.), situated to the west and south of the volcanic centre of Tinderet. Brief visits were also made to the sites of Ombo and Mariwa twelve miles west of Kisumu[1].

At Napak, in addition to the sites (Napal I–III) previously described by Bishop[2,3], four new faunal localities were investigated (Napak IV, VI, VII and VIII) which were discovered in 1960 by Dr. A. F. Trendall of the Geological Survey of Uganda during routine sheet mapping. We were fortunate in finding another new site (Napak V) during the expedition.

The first fossils from the vicinity of Moroto Mountain (site Moroto I) were found in 1959 by J. G. Wilson of the Uganda Department of Agriculture, who also discovered the original Napak site, and who kindly described to us the location of his new discovery[4]. Again we were fortunate in finding a second site two miles farther north (Moroto II).

---

* Present address: The Curator, The Uganda Museum, P.O. Box 365, Kampala, Uganda.

We thank Dr. L. S. B. Leakey, who kindly invited us to make observations on the geology of the recently discovered Lower Pliocene or Late Miocene site at Fort Ternan[5].

Geological mapping was undertaken at each of the fossil localities using air-photographs as base-maps. A level and staff were used in conjunction with a pair of surveying aneroids to construct levelled profiles on which geological observations were plotted. In some instances additional large-scale maps were prepared by use of a plane-table. The main object of the work was to study the nature of the sediments in relation to the total fauna at each of the fossiliferous localities. Palæo-ecological reconstructions could then be attempted as a background against which to assess observed differences in preservation or in the composition of the various faunal assemblages.

Sediments

The Koru, Songhor, Ombo and Mariwa sites, like those of Karungu, Rusinga and Mfwanganu associated with the Rangwa volcano, have been known for many years, and their faunas are well documented as a result of various British–Kenya Miocene Expeditions[6]. Their geology has been described by Kent[7], Shackleton[8] and officers of the Kenya Geological Survey[9–11]. Although the detailed observations, sections and maps made in all the areas visited during the recent expedition will be published later, it is proposed to outline here preliminary notes on the new exposures at Napak, Moroto and Fort Ternan.

Napak. The eight fossil sites can be broadly divided into two groups on the basis of their lithology: (1) Sands, gravels and tuffs occurring at the base of the volcanics and resting directly on the basement rocks (Sites II, III, VI, VII and VIII); (2) bedded tuffs and agglomerates within the volcanic pile, and some 500 ft. above the basement surface (Sites I, IV and V).

The basal sediments are principally coarse sands, grits and gravels with abundant basement rock fragments, and a few tuffaceous horizons. They appear to be of fluviatile origin and were formed before and during the earliest stages of the volcanic activity. They resemble closely the similarly situated deposits at Moroto which are described here.

The higher sites within the pyroclastic sequence are situated as described by Bishop in the original note on Napak I (refs. 2 and 3), and recently they have been mapped more extensively by Trendall[12]. The fossiliferous series occurs between two coarse agglomerate horizons, and consists of 130 ft. of predominantly grey horizontally bedded fine to coarse tuffs. These are composed largely of volcanic rock fragments and individual crystals, with a calcite cement. Some layers are rich in biotite, and several of the horizons can be classified as crystal-tuffs. Reddened zones and layers of concretionary calcareous nodules suggest time-gaps, as does the abundance of fossil wood at certain levels. However, no definite weathered profiles were observed on top of any particular bed. The deposits mainly represent sub-aerial accumulations of primary volcanic detritus, perhaps locally sorted by water in the form of surface run-off.

Moroto. At the two Moroto localities, which are some 55 miles north-east of the Napak sites and approximately 12 miles north-west of the summit of Moroto Mountain, the fossil-bearing sediments are grits and gravels resting directly on steeply dipping basement gneisses. The deposits appear to be largely fluviatile, and they infill valleys up to 300 ft. deep, incised into the basement surface. Most of the fragments are derived from the underlying gneisses; but a few of volcanic origin are also present. The fossiliferous horizons in the grits have a calcareous cement.

At both localities, the sediments are overlain by olivine–basalt flows which are fresh in the centre but have rotten vesicular tops and bottoms. The total thickness of sediment exposed at Moroto I is only 12 ft. At Moroto II, up to 80 ft. of sediments were seen but they were only locally fossiliferous. At the

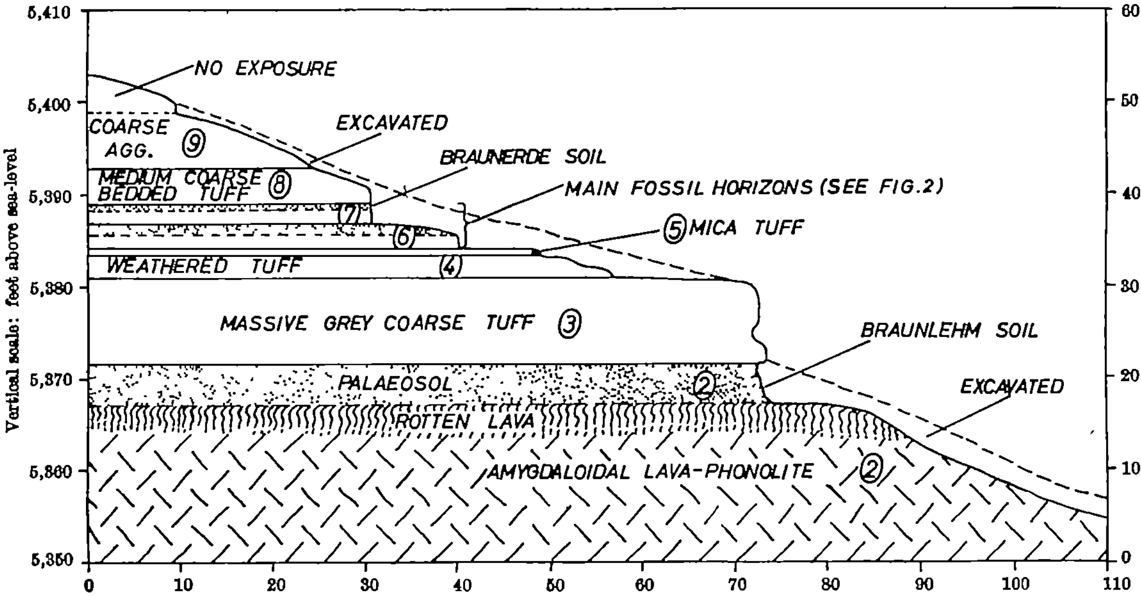

Fig. 1. Levelled section across the Fort Ternan excavation showing pyroclastics (left blank), lava (crossed ornament) and palæosol horizons (stipple)

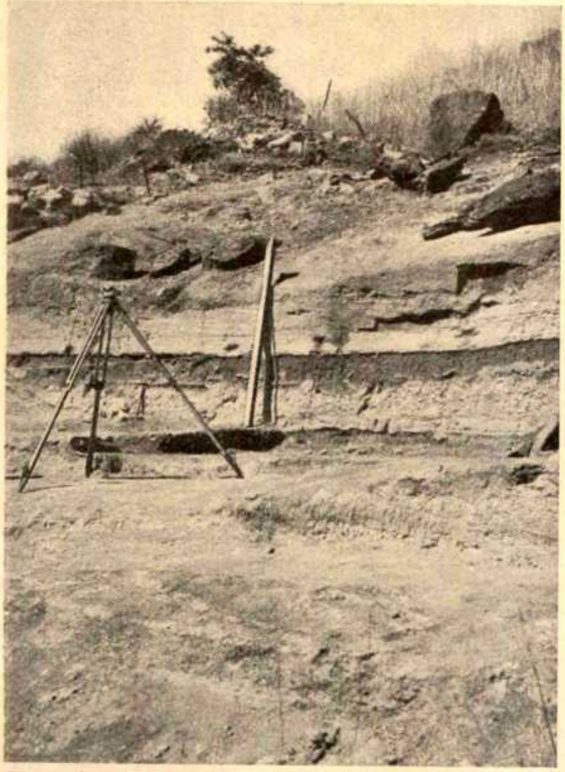

Fig. 2. Detail of the upper section of the Fort Ternan excavation. The tripod stands on grey calcareous crystal tuff (Bed 5). The weathered top of Bed 6, fossiliferous tuff, is seen below the base of the levelling staff while the geological hammer rests beside fossil mammalian bones *in situ* in the coarse tuff of Bed 7. This bed has a pronounced palæosol (dark horizon above hammer haft), developed at the top of it which contrasts sharply with the fresh bedded calcareous tuff of Bed 8. The blocks on the hill slope are derived from the upper phonolite (Bed 11)

latter site, the present-day stream is etching out a pre-existing valley cut in basement complex gneisses.

Fort Ternan. The site at Fort Ternan was referred to recently by Dr. L. S. B. Leakey[5], who published our levelled profile through the deposits as his Fig. 1 (p. 691). However, this diagram was not accompanied by details of the succession. The following is the sequence exposed immediately above and below the principal fossiliferous horizons. The numbers of the beds refer to those on the previously published section and to Fig. 1 of this article.

Bed No.			Thickness (ft.)
11	Phonolite lava (Losuguta type)	seen to	20·0+
	no exposure, about 40 ft.		
10	Hard grey tuff	seen to	3·0
	no exposure, about 10 ft.		
9	Very coarse agglomerate	seen to	5·0
8	Medium to coarse bedded tuff with agglomeratic horizons		4·5
7	Grey coarse tuff (fossiliferous) with weathered top		2·5
6	Grey medium tuff (fossiliferous) with weathered top		2·0
5	Grey medium calcareous crystal-tuff		0·5
4	Grey medium tuff, deeply weathered		2·5
3	Massive grey coarse tuff		9·0
2	Rotten amygdaloidal lava (Phonolite—? Losuguta type) with deeply weathered upper surface		50·0
1	Massively bedded very coarse agglomerate	seen to	60·0

The beds exhibit a gentle dip of 1 in 25 to the north, and have suffered faulting locally. With the exception of the lavas, all the beds are stratified tuffs of variable grade, some reaching the coarseness of agglomerate. Preliminary examination of these deposits shows that many have a matrix of finely disseminated volcanic dust while others have a calcite cement. The fragments are mainly of local volcanic rocks and include many individual crystals with Bed 5 essentially a crystal-tuff.

Although local wash-outs and the effects of water-sorting, probably the result of rain-wash on the freshly deposited ash slopes, can be seen on some of the horizons, the majority of the beds are sub-aerial accumulations of original primary volcanic ash.

Fig. 1 shows a detailed section through the beds exposed by Dr. Leakey's excavation, from the top of Bed 2 to the base of Bed 9. In this sequence weathered profiles can be seen developed on the lower lava and on several of the overlying pyroclastic horizons (Fig. 2). Dr. I. W. Cornwall has made a preliminary examination of material from two of the weathered profiles. We are indebted to him for the information that three samples spanning the weathered top of Bed 2 reveal it to be a palæosol of Braunlehm type, while two from the top of Bed 7 suggest a palæosol with Braunerde characteristics.

It seems probable that when large-scale excavations are carried out at Napak, palæosols will be found similar to those at Fort Ternan. Deep cuts are necessary before the palæosols can be seen clearly, as near the surface they merge into the zone of present-day weathering and slope creep.

The primary and sub-aerial nature of the Fort Ternan deposits is clear, and almost identical lithologies argue similar environments at Napak and Songhor. It is of interest to note the closely comparable sequence of numerous primary crystal-tuffs with soil profiles recently referred to by Curtis and Evernden as occurring in the Lower Pleistocene Bed I of the Olduvai Gorge section in Tanganyika[13].

From considerations of their petrology and altitude (5,350–5,470 ft.), the Fort Ternan lavas and pyroclastics fit into the sequence of strata outlined by Binge[11]. They represent horizons near the base of his Kericho phonolites (Tvp_1) which were derived from the south and are intercalated with the upper layers of his tuffs and agglomerates (Tmf) which had their origin from Tinderet to the north.

Although no fauna was excavated by us from Fort Ternan, a potassium-40/argon-40 date of about 14 million years has been published[5]. The tuffs and agglomerates, however, also include near their base the typical Lower Miocene assemblage of Songhor (4,420–4,490 ft.) and they immediately overlie fossiliferous beds of this same age at Koru (4,750–4,800 ft.). This suggests a prolonged 'Miocene' history for a largely ash cone on the site of Tinderet. A similar

situation with a greater amount of pene-contemporaneous erosion is suggested by the superimposition of Burdigalian and Pontian mammalian faunas on Maboko Island near Kisumu. At Tinderet, the later outwellings of phonolitic nephelinites, nephelinites, through Kenya-type phonolites to basanites and tephrites as described by Binge[11], are probably all of post-Miocene age.

Fauna

At each locality every fossil fragment seen was collected, whether identifiable or not. The results of the 1961 collections are recorded in Tables 1 and 2, and in Table 1 are compared with the figures for Napak I 1958. The following tentative conclusions are drawn concerning the nature of the assemblages:

(1) There are two distinct types of preservation and assemblage represented. In Table 1 are included only those sites where fossils were stratified beneath a mantle of calcareous sub-aerial pyroclastic material. In this group it is notable that skulls, teeth and jaws comprise 12–25 per cent of the total finds. The 'Better' bones, that is, post-cranial bones preserving recognizable facets and form, show a similar range.

The fact that far too many skulls, teeth and jaws are represented when considered in relation to the number of bones, would seem to imply selective preservation. This presumably reflects the scavenging activities of carnivores and rodents in removing a large proportion of the more edible bones from the debris which lay on the temporary land surfaces. This is supported by the fact that many of the bone fragments retain signs of gnawing and chewing. From the Table 1 localities the non-mammalian fossils collected include fossil wood, seeds, fruits and land gastropods.

(2) The sites included in Table 2 are situated at the base of the main volcanic series, and the fossils occur in calcareous sands and grits resting unconformably on the basement complex and consisting largely of quartzose fragments derived from these rocks. The very different percentage of skulls, teeth and jaws, ranging from 1–6 per cent, reflects in part a more correct proportion of cranial to post-cranial fragments, but also the much poorer preservation resulting in the fragmentation of the majority of the specimens.

The contrast in lithology between the two groups of sites is seen also in the non-mammalian fauna. These basal grits characteristically yield fossils of crocodile and chelonia. At Ombo, fish were represented in the form of jaws of *Protopterus*, and at two of the Napak sites valves of an oyster were found. Also, at Ombo and Mariwa the mammals included *Dinotherium*. These are all absent from the sub-aerial volcanic environments, and provide evidence in support of a fluviatile origin for the basal deposits.

* At another site near Koru several specimens of *Dinotherium* were found in sediments with a different lithology.

(3) Table 1 records the characteristic high percentage of rodents preserved in all the sub-aerial tuff environments. In Table 3, percentages of the main mammalian groups in the assemblages of skulls, teeth and jaws at Napak and Songhor are compared with similar figures for Mfwanganu[14], and Koru (based on collections made between 1927 and 1932 housed in the Department of Palæontology, British Museum (Natural History)). The proportions of the main groups reveal a remarkably constant picture at the four sites, and contrast sharply with the figures for the more sparse basal assemblages at Napak and Moroto where the small fauna is completely absent.

(4) That collection failure is also a factor to be considered, is shown in Table 1. Practically all the easily seen mastodont fragments from Napak I were collected in 1958 and only an additional eight fragments were found on return in 1961. By contrast, only one-fifth of the 1958 finds were small rodents although they represent three-fifths of the 1961 total, and were often represented by isolated incisors.

(5) The fossils from Napak I, IV and V are from identical lithologies on the same stratigraphical horizon and are virtually contemporaneous. They must represent very similar environments within one mile of each other on the slopes of the periodically active volcano. Yet there are significant differences in the mammalian assemblages which must imply local ecological changes. Rodents form 80 per cent of the fauna at Napak IV but only 30 per cent at Napak I. Ruminants account for almost 30 per cent of the total at Napak V but only 2 and 4 per cent at Napak I and IV. Primates are most numerous at Napak V where they represent almost 15 per cent of the total.

In assessing the abundance of different groups, it has been assumed that each find represents one individual. Only in the case of the primates at Moroto II and of the large primate from Napak V, does it seem probable that several finds represent only one individual.

(6) At Songhor, it is more difficult to give full weight to the percentages shown in Table 3, as a great deal of collecting has been already made. However, the broad similarity both in actual genera and species and in the relative proportions of the different family groups, between the finds from Songhor and those from Napak, Koru and Mfwanganu, is very striking.

(7) At one locality in the main Songhor I exposure, from an isolated area of fine-grained reddish

tuffs known as the 'Red Outlier', which measures only some 10 ft. in diameter, 97 mammalian fossils were collected during September 1961. These included 46 unidentifiable bone fragments, 22 better-preserved bones, and 29 skulls, teeth and jaws. This was the richest deposit which we studied, although the outcrop at Songhor II (Table 1) suggested a similar local fossiliferous patch within the tuff. At these sites again too many skulls, teeth and jaws (30 and 25 per cent of the total finds respectively) were associated with too few post-cranial bones. The Red Outlier assemblage showed the usual domination by rodents with 23 out of the 29 cranial fragments.

These fossiliferous patches within the tuffs recall on a small scale the local concentrations of fossils at Napak I, IV and V. These three areas, each with a maximum diameter of less than 50 yards, yielded the vast bulk of the fauna from the Napak upper level although there was well over a mile of good exposure in beds which appeared to be of identical lithology.

(8) The Napak sites I, IV and V have now yielded a faunal list of at least 29 genera or species as follows: primates 6, insectivores 1, rodents 6, carnivores 6, anthracotheres 1, artiodactyls 4, perissodactyls 3, proboscideans 1, hyraxes 1. The majority of the genera and species is also recorded from the other Lower Miocene (Burdigalian?) assemblages at Rusinga, Mfwanganu, Songhor and Koru, but these contrast sharply with the Fort Ternan assemblage. It therefore seemed desirable to collect where possible specimens of potassium-bearing volcanics associated with the various fossiliferous horizons, with the view of potassium-40/argon-40 dating. The specimens are being dated by Drs. J. F. Evernden and G. H. Curtis of the Department of Geology, University of California, Berkeley, and Dr. P. Damon, University of Tucson, Arizona, to whom we are indebted.

It is hoped that the association of the dates with the faunal evidence will be of assistance in assessing the reliability of these techniques when applied to Tertiary volcanic deposits. Also, as more absolute ages become available it may be possible to review the palæontological data for the various localities. It seems desirable to record differences in abundance, as in Tables 1–3, in addition to identifying lists of species. This is essential if the faunas are to yield evidence on rates of evolutionary change and on the relative importance of ecological differences between the various sites.

(9) The finds from Uganda included 13 primate specimens from Napak and 3 from Moroto. This brings the total of primate finds from the Napak upper level to 18, of which at least 9 represent the genus *Proconsul*. The two finds from the new Moroto II site included the left maxilla of a large *Proconsul*. A further expedition to this locality in December 1961 by Prof. D. B. Allbrook and other members of the Department of Anatomy, University College, Makerere, yielded several more *Proconsul* fragments, including the right maxilla of the original individual. These primate specimens, together with those from Napak, will form the subject of a further publication shortly.

The work was financed by a scientific grant-in-aid from the Royal Society. We also thank the Directors of the Uganda and Kenya Geological Surveys, the Trustees of the Uganda Museum (for valuable assistance with equipment and personnel), Dr. and Mrs. M. Posnansky of Kampala, Mr. and Mrs. R. O. Doenhoff and Mr. and Mrs. J. McLeod of Songhor, Mr. F. Wicker of Fort Ternan, and Mr. and Mrs. S. Stevenson of Irire, Karamoja, for much personal kindness. Finally, we thank Prof. T. Neville George for his critical reading of the text, and the numerous people who helped in various ways or who are at present actively concerned in further specialist studies in preparation for the full report on the work.

MOLECULAR ORIENTATION OF SOME KERATINS

By Dr. C. EARLAND, P. R. BLAKEY and J. G. P. STELL

Department of Textile Industries, Institute of Technology, Bradford

Wool and related hairs (α-keratin) show no birefringence in transverse section, and it is concluded that the preferred molecular orientation must lie in the direction of the fibre axis. In the case of feather, however, which is substantially in a β-configuration, Astbury and Bell[1] observed more than twenty years ago that the molecular orientation of a thin outer layer of quill was at right angles to the feather axis. Recently, we have[2], using the polarizing microscope, found that in the case of goosewing quill, the region showing transverse orientation represented approximately the exterior third of the calamus (root-end) wall, reducing to one-seventh at the rachis. Preliminary X-ray diffraction work also indicated that the pattern of calamus is in fact composite and arises from two structures at right angles to each other.

Thick tactile whiskers, such as those of lion and tiger, exhibit Maltese-cross birefringence when a transverse section is viewed in polarized light, and it has been concluded that in these structures it is the interior region surrounding the medulla that possesses tangential orientation at right angles to the axis[2].

In the present investigation an examination has been made by X-ray diffraction and polarizing microscopy of a number of keratinous materials to determine the extent to which molecular orientation at right angles to the longitudinal axis is general in these structures. The materials examined included hairs, cattle horn and mammalian quills as these are representative of a wide range of keratinous structures. Baleen plate of whale ('whalebone') and rhinoceros horn have been studied also as these materials are interesting in that their complex structures may be regarded as intermediate between normal horn and hair. Some further observations on tactile whiskers and feather calamus are included in the present communication as they have confirmed the conclusions put forward previously regarding the molecular orientation of these structures.

The calamus was isolated from white goose feathers with scissors. Shavings of rhinoceros horn were taken near the root and both from living animals and museum specimens. Strips of commercial 'whalebone' were used with the fringe fibres attached. Although it has been suggested that hydroxyapatite may be present in the whalebone fringe fibres of the fin whale[3], it was found that the calcium phosphate content of the baleen used in this work was 1·0 per cent only. Prior to examination, all materials were degreased by Soxhlet extraction with alcohol and then with ether.

Transverse sections were obtained by hand-sectioning with a razor blade or by the use of a microtome. Specimens were mounted in xylene and viewed in ordinary and convergent polarized light. Examination at elevated temperature was made by enclosing the specimen in an electrically heated aluminium block, the apparatus being similar to that used for observing the shrinkage temperature of collagen.

Although the transverse sections of whisker were of uniform thickness, the birefringent region exhibited very marked multicolouring when viewed in white light, indicative of optical heterogeneity. In these circumstances no quantitative measurements of birefringence could be made, although the insertion of a quarter wave plate showed that in all cases the birefringence was negative.

X-ray diffraction photographs were obtained using a flat plate camera and copper $K\alpha$-radiation from a Raymax rotating anode crystallographic unit operating at 40 m.amp and 40 kV, with the beam parallel, radial or tangential to the axis. Where comparison photographs were required a quadrant type cassette was used.

(*a*) *Feather calamus*. It had been shown previously that the regions exhibiting differing birefringence were separated by a sharp boundary line[2], and there was no evidence for the two structures merging into each other. This suggested that it should be possible to separate the two phases mechanically and this was, in fact, achieved by the following method. A sample of calamus was mounted in a stretching frame in such a manner that tension could be applied tangentially in the plane perpendicular to the feather axis. The specimen was steamed for about 2 min in this state, when it split spontaneously into its two components. These components were then mounted in the X-ray camera with the direction of the quill axis vertical. X-ray diffraction photographs showed that although the molecules of the two regions possess the same configuration, in the case of the inner region the orientation is parallel to the feather axis, but in the case of the outer region it is perpendicular to this axis.

(*b*) *Tactile whiskers*. It has been reported previously[2] that the interior regions of transverse sections of whiskers of lion and tiger exhibit Maltese-cross birefringence in polarized light. Myelin sheaths however, also exhibit the same phenomenon and it has been concluded that this form of birefringence may arise from two materials within the sheath, the protein molecules which lie tangentially and incrusted lipoid materials with the molecules orientated radially[4]. Since the latter birefringence is reduced by solvent extraction[5], it was concluded that the Maltese-cross birefringence of whiskers was due solely to tangential orientation of protein molecules since the materials used had been extracted thoroughly. However, the region showing this phenomenon is always in the vicinity of the medulla where lipoid materials are very probably present, and therefore the birefringence of these materials was examined at elevated temperatures, since it is known that the birefringence due to lipoids disappears at 100° C (ref. 5). It was shown that a transverse section of lion whiskers viewed in polarized light with the specimen heated to 115° C gave a Maltese cross as sharp as that at room temperature, and it must be concluded that the original views regarding the cause of this birefringence are correct.

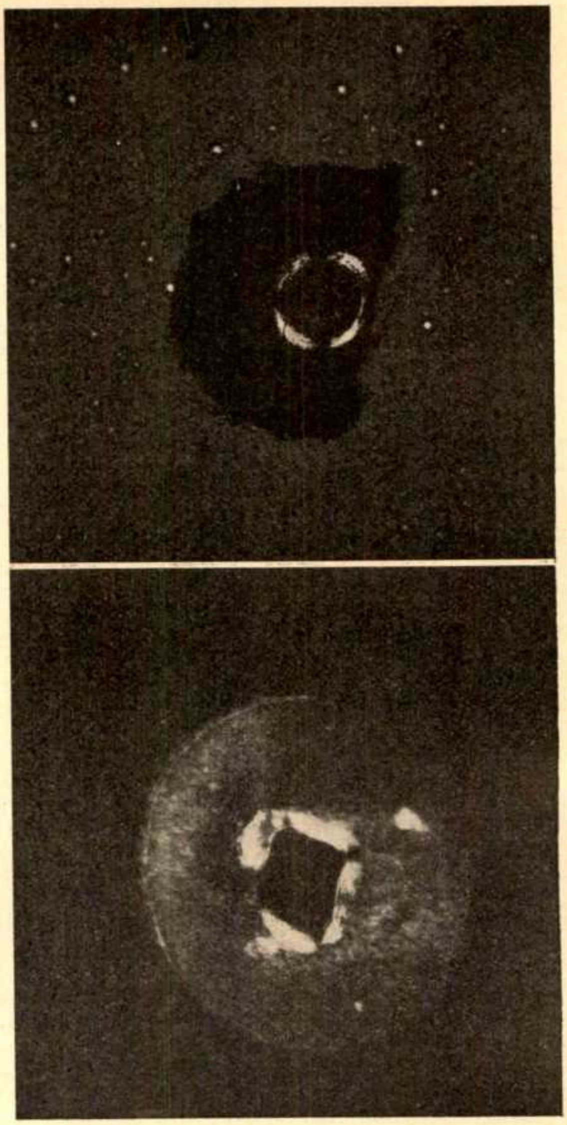

Fig. 1. Top, transverse section of whisker of lion viewed in polarized light at 115° C (× 45); bottom, transverse section of horse hair viewed in polarized light (× 400)

(*c*) *Miscellaneous animal hairs.* In view of the fact that the very extensive literature on the fine structure of wool makes no mention of Maltese-cross birefringence, it was scarcely surprising that none was found in this investigation. The literature on heavily medullated wools and kemp, which are more akin to the tactile whiskers than the finer wools where medulla is completely absent, however, is less comprehensive and these materials were, therefore, carefully examined but again no birefringence was observed.

Although it was not possible to make a complete survey, a very large number of other animal hairs was also examined, but only one example of Maltese-cross birefringence was found. This was in monster horse hair, and a transverse section taken near the root is shown viewed in polarized light in Fig. 1.

(*d*) *Cattle horn.* X-ray diffraction showed that in the case of horn, which consists of about ten concentric laminates which may be separated readily mechanically, the outer layer has very good orientation with the molecules lying perpendicular to the axis and tangentially. The inner layers, generally, did not show such good orientation, but the orientation showed a tendency to be parallel to the horn axis, although occasionally a region could be found with molecular orientation similar to that in the outer layer. No evidence could be found for a β-configuration.

A transverse section of horn, about 0·001 in. thick, obtained by using a shaping machine, was mounted in xylene and viewed in polarized light. The outer layer, which amounted to about one-third of the thickness of the horn, was highly birefringent whereas the remainder was birefringent to a lesser degree. Thus the molecular orientation as shown optically was consistent with the results obtained from X-ray diffraction.

(*e*) *Baleen plate* ('*whalebone*'). Whalebone, after extraction with alcohol and ether to remove grease, gave a normal α-keratin X-ray diffraction pattern. A transverse section of this material viewed in normal light is shown in Fig. 2, top. In the lower portion the fibres can be seen set in the matrix, and the upper portion consists solely of layers of horny embedding material. The laminated nature of the latter may be seen clearly and it is thus very similar to cattle horn. The same section viewed in polarized light (Fig. 2, bottom) shows that each embedded fibre exhibits a Maltese cross and is very similar to the whiskers of lion and tiger. The fringe fibres which emerge from baleen also show the same effect.

(*f*) *Rhinoceros horn.* There is considerable confusion in the literature regarding the structure of rhinoceros horn and an attempt to clarify the position has been made recently by Ryder[6]. There is no doubt that, whereas cattle horn is composed of sheets of keratinous material, rhinoceros horn consists of longitudinal filaments. These tend to separate, particularly at the proximal end, which, no doubt, gave rise to the earlier statements that rhinoceros horn is composed of matted hair[7,8]. Although the latter is untrue, it has been shown[6] that the interfilamentous horn is much sparser than, for example, in the case of baleen plate (Fig. 2, top), and the filaments are packed so tightly together that they are often multi-sided rather than circular. Morphologically, it is probably not incorrect to regard both baleen plate and rhinoceros horn as intermediate between hair and cattle horn.

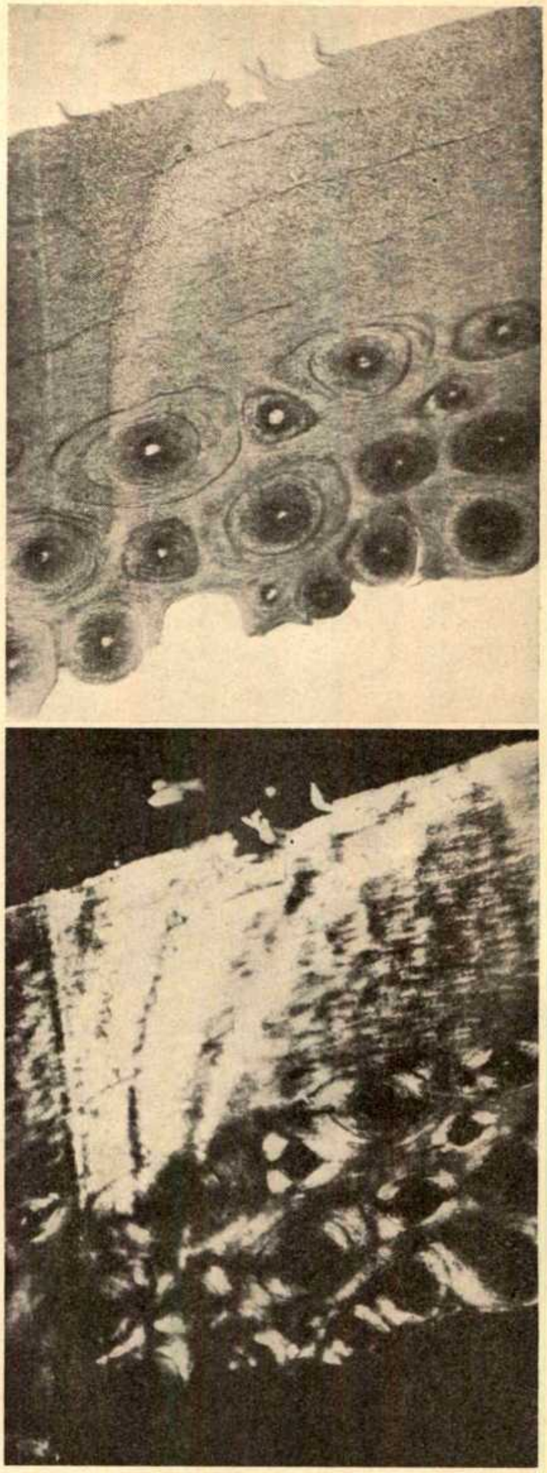

Fig. 2. Top, transverse section of baleen plate viewed in normal light (× 60); bottom, similar section viewed in polarized light (× 60)

Concurrently with the publication of the discovery of transverse orientation in whiskers of the cat family[2], Ryder[6] published photomicrographs of transverse sections of the individual filaments comprising rhinoceros horn. The latter showed clearly longitudinal cell structures orientated tangentially in the plane of the section and were, in fact, very

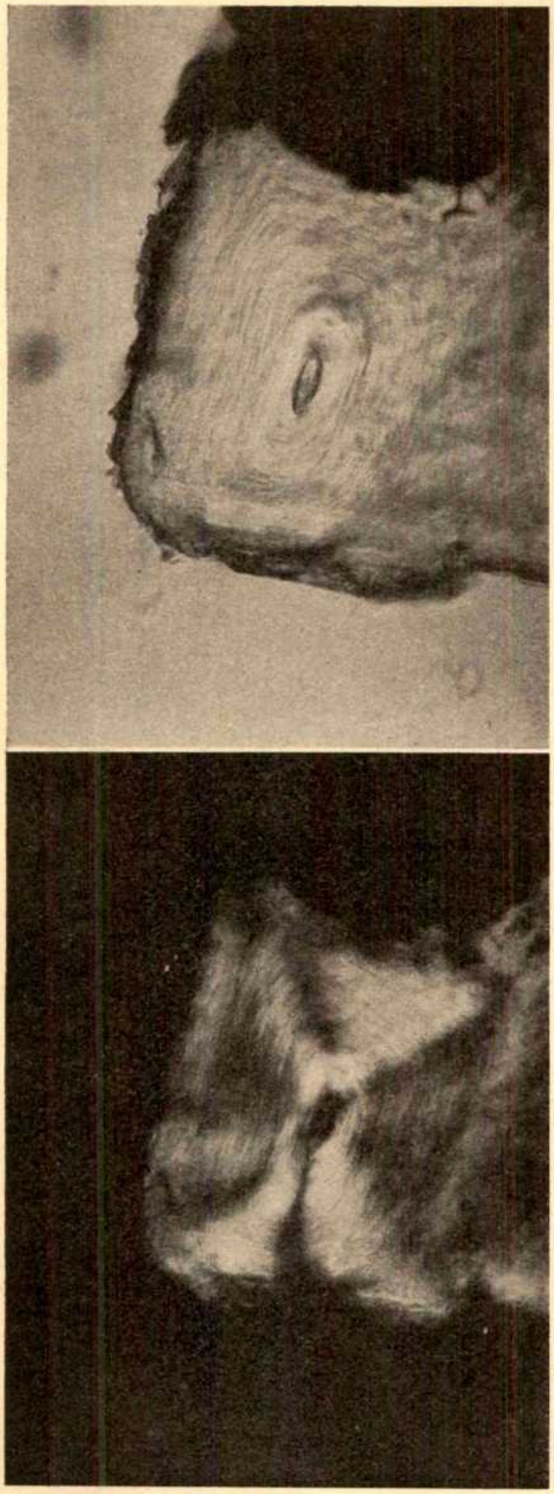

Fig. 3. Top, transverse section of a single filament of the horn of the black African rhinoceros viewed in normal light (×50); bottom, similar section viewed in polarized light (× 50)

similar to sections of whisker. It was therefore anticipated that these sections would exhibit Maltese-cross birefringence in polarized light. In Fig. 3 is shown a transverse section of a filament from the horn of the black African rhinoceros (*Diceros bicornis*) viewed in polarized light and a similar section taken from the horn of the Indian rhinoceros (*R. unicornis*) in polarized light is shown in Fig. 4.

Of the five living species of rhinoceros, the horns of four were available for examination, the exception being the Sumatran rhinoceros (*R. sumatrensis*). A comparative investigation of these four keratins was therefore made, and the results are summarized in Table 1.

Although Table 1 suggests that the Asian rhinoceroses have horns superficially more resembling

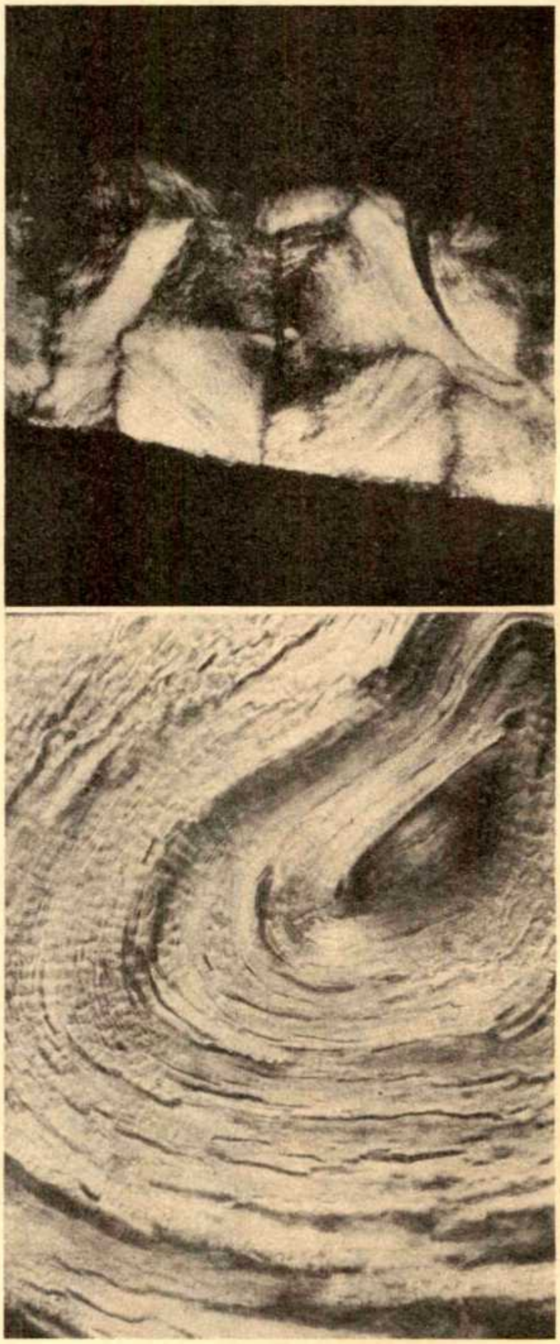

Fig. 4. Top, Transverse section of the horn of the Indian rhinoceros viewed in polarized light (× 50); bottom, transverse section of a portion of a filament of the horn of the white African rhinoceros viewed in normal light (× 400)

Table 1. STRUCTURE OF RHINOCEROS HORNS FROM DIFFERENT SPECIES

Species*	Macro structure	Appearance in polarized light of transverse section	X-ray diffraction pattern
Indian (2) (*R. unicornis*)	General appearance like cattle horn.	Maltese-cross effect (Fig. 4).	Poorly orientated α-pattern. Strong apatite reflexions.
Javan (1) (*R. sondaicus*)	Filaments very firmly embedded in matrix.	Patchy birefringence. Filaments too irregular to produce cross.	Poorly orientated α-pattern. Apatite reflexions absent.
African Black (2) (*Diceros bicornis*)	General appearance like bundle of bristles.	Maltese-cross effect (Fig. 3).	Poorly orientated α-pattern. Apatite reflexions absent.
African White (1) (*Cerathotherium simus*)	Filaments readily separated.	Patchy birefringence. Filaments too irregular to produce cross.	Poorly orientated α-pattern. Apatite reflexions absent.

* The number of specimens examined from different animals is given in parenthesis.

cattle horn that the African species, and *R. unicornis* is the only species containing apatite as a major constituent of its horn, it must be borne in mind that the observations have been made on a small number of animals.

In feather and cattle horn the keratins possessing transversal and longitudinal orientation are located in well-defined regions. In the case of rhinoceros horn, however, the poor X-ray diffraction pattern produced when the specimen was mounted longitudinally and the extensive but rather ill-defined Maltese-cross pattern shown by a transverse section in polarized light, suggest that the protein molecules showing different orientations are more intimately associated.

(*g*) *Mammalian quills.* The birefringent zones exhibited by transverse sections of porcupine and hedgehog quills in polarized light were less extensive than in the other keratinous structures examined. Nevertheless, the four extinction positions were clearly visible and there can be no doubt that a thin layer possessing transverse orientation is present. If the complex internal structure of quill be regarded as a medulla, the location of this layer is not dissimilar to that in tactile whiskers.

Thus, it has been shown conclusively by X-ray diffraction and polarizing microscopy that feather calamus and cattle horn are polyphase in structure, possessing molecular orientation of the protein molecules at right angles to the main structural axis, in addition to parallel orientation.

Strong evidence has been obtained also from polarizing microscopy that similar structures are present in rhinoceros horn, baleen plate and mammalian quills, but in hair and wool with a single exception the preferred molecular orientation lies exclusively in the direction of the fibre axis.

It is considered that the biological significance of these structures is to prevent the splitting that would occur if the structural elements were laid down exclusively in one direction.

We thank Dr. L. Harrison Matthews and Mr. E. H. Tong of the Zoological Society of London, Dr. G. B. Corbet of the British Museum (Natural History) and Dr. E. Lees of the Department of Biological Sciences, Bradford Institute of Technology, for providing specimens and advice. One of us (J. G. P. S.) is a Wool Textile Research Council Fellow.

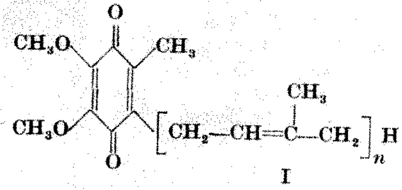
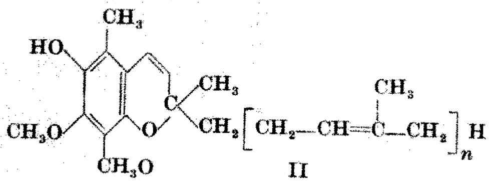
UBIQUINONE AND UBICHROMENOL

Ubiquinone and Ubichromenol in *Torula* Yeast

UBIQUINONES (I) and ubichromenols (II) are isomeric.



I



II

Ubichromenol$_{10}$ ($n=9$)[1] has been found in various animal tissues and ubichromenol$_7$ ($n=6$) occurs in a *Torula* yeast (commercially dried).

The isomerization can be effected in the laboratory by various procedures involving the use of a catalyst[2,3]. These lead to a racemic product, but the preparations from human kidney[4] and from *Torula* yeast were optically active.

The question whether ubichromenol is or is not a natural product for which it is reasonable to seek a function is not easily settled, although evidence has been reported[5] which supports a natural origin from some animal tissues. It became necessary to investigate the problem in the case of *Torula* yeast.

A commercial, dried *Torula* yeast (*Candida utilis*), kindly given by the Lake States Co., New York, and designated type *B*, was analysed for ubiquinone (UQ) and ubichromenol (UC) with the results shown in Table 1.

Simple extraction of lipid from yeast is an inefficient process[6], and the failure in experiments 1, 2 and 3 to achieve the yields of UQ and UC which occur after alkali digestion (saponification) of the yeast is not surprising. Alkali and heat tend to destroy UQ and UC, and saponification should aim at liberating these substances with minimal destruction. The fact that the ratio UC/UQ in Table 1 is nearly constant argues against conversion of UQ in the saponification

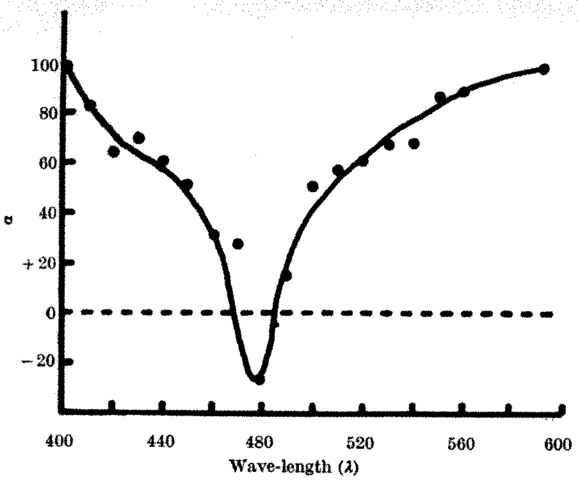


Fig. 1. Optical rotatory dispersion in petrol of ubichromenol$_7$ isolated from dried *Torula* yeast

process. The UQ and UC were separated and assayed according to the method of Green *et al.*[7] except that the second dimension of the paper chromatography was omitted.

A completely independent analysis carried out on another sample of the same yeast gave UC 485 μg/g, UQ 250 μg/g. In this experiment the unsaponifiable matter was twice chromatographed, once on alumina and once on magnesia, and by comparison with the results in Table 1 artefact formation cannot have occurred on more than a quite small scale, if at all.

Analyses in other laboratories[6] have given figures of UQ 341 μg/g and UC 420 μg/g.

A sample of yeast was digested with methanolic alkali containing pyrogallol for 1 h (Table 1). The ether-soluble unsaponifiable matter was then subjected to chromatography on acid-washed alumina (Brockmann grade 2). After further purification, involving chromatography on magnesium oxide, a sample was obtained which exhibited absorption maxima in *cyclo*hexane at 275 and 332 mμ ($E^{1\%}_{1\,\mathrm{cm}}$ of 123 and 50, respectively) and minima at 260 and 300 mμ ($E^{1\%}_{1\,\mathrm{cm}}$ of 75 and 24, respectively). The characteristic inflexion at 282 mμ was also clear. Reversed-phase partition paper chromatography indicated that the product was mainly ubichromenol$_7$ with small amounts of ubichromenol$_8$ as the contaminant. This is consistent with the $E^{1\%}_{1\,\mathrm{cm}}$ values quoted here, for at $\lambda_{\max}$ 275 mμ pure ubichromenol$_{10}$ has an $E^{1\%}_{1\,\mathrm{cm}}$ of 96·1, and so pure ubichromenol$_7$ and ubichromenol$_8$ would be expected to have $E^{1\%}_{1\,\mathrm{cm}}$ of 125·0 and 104·9, respectively. The material was therefore free of other impurities.

Table 1. Yields of Ubiquinone and Ubichromenol from Dried *Torula* Yeast using Various Methods of Extraction

Method of extraction	UQ* (μg/g)	UC† (μg/g)	UC/UQ
1. Acetone/ether, boiled, filtered	97	142	1·46
2. (*a*) Ether (Soxhlet)	96‡	148	1·54
(*b*) 1 h saponification of remaining yeast	173	268	1·55
3. Chloroform/methanol, boiled, filtered	126	190	1·51
4. ½ h saponification	270‡	416	1·54
5. 1 h sponification	266‡	419	1·58
6. 1½ h saponification	215‡	350	1·63
7. 1 h acid hydrolysis	225§	352	1·56

*UQ, ubiquinone estimated as ubiquinone$_7$.
† UC, ubichromenol estimated as ubichromenol$_7$.
‡ Refluxed *x*g with 3 *x*ml. 5 per cent (w/v) methanolic pyrogallol and 3·5 *x*ml. 25 per cent (w/v) aqueous KOH. Then diluted with water and extracted with ether.
§ Same as saponification but with 6 N HCl instead of KOH.

Table 2. Effect of Drying on the Amounts of Ergosterol, Ubiquinone and Ubichromenol in Fresh *Torula* Yeast (*Candida utilis*)

(Yeast dried at 90° C in an open beaker)*

Period of heating	Ergosterol (mg/g dry weight)	Ubiquinone (μg/g dry weight)	Ubichromenol (μg/g dry weight)
None	Not recorded	762 (±25)†	17
23 min	4·11	666	20
60 min	4·09	872	22
3 h	4·00	602	21
6 h	4·32	688	22

* 75·65 per cent of wet weight lost on freeze-drying.
† Mean of three readings.

A sample (31 mg) of this ubichromenol was then sent to Glaxo Laboratories for investigation of its optical activity. Since ubichromenol is known to be photo-labile and is probably also thermo-labile, it was kept in a sealed tube in a thermos flask containing solid carbon dioxide during transport. We are indebted to Dr. M. Barnard, Mr. A. C. Parker and others of Glaxo Laboratories for the following report:

"The solution of ubichromenol (from *Torula* yeast) in petroleum ether (b.p. 40–60°) showed a negative peak at 480 mμ with [α] of −26° (±5°). The possible error in [α] is due to the use of dilute solutions, for the sample had a high optical density."

The results are recorded graphically in Fig. 1.

Ubichromenol$_{10}$ has previously been examined[4] for us in the Glaxo Laboratories when a product isolated from human kidney was compared with a product obtained by Dr. O. Isler *et al.* (Hoffmann-La Roche and Co., Basle) by the Links[2] procedure from ubiquinone$_{10}$ (ref. 5). The synthetic compound was optically inactive. The natural compound was examined in chloroform solution and qualitative curves on the fresh solution resembled that for ubichromenol from *Torula* yeast shown in Fig. 1. On the following day there was a negative peak at 430 mμ with [α] of −50°. On the third day the solute had evidently decomposed.

The yeast sample examined for optical activity was obtained in an experiment in which saponification was conducted for 1 h and contained a minimal proportion of racemic ubichromenol artefact (Table 1).

Inasmuch as ubichromenol is not always found in extracts from tissues fairly rich in ubiquinone, the case in favour of the view that it may be an artefact of laboratory manipulation is far from strong. On the other hand, the erratic distribution might be taken as indicative of formation of UC as a result of biological differences in the sense that UQ is converted to UC, but only under special conditions. This possibility warrants investigation.

Accordingly, live yeast was obtained by courtesy of the Lake States Co. It came in two forms, one as an agar slope and the other (through Dr. J. Green, of Vitamins, Ltd.) as a frozen pressed cake (not dried). The smaller sample was for inoculating cultures and the larger sample for analyses.

Rather surprisingly, the UC content of the fresh yeast was almost negligibly low, but the UQ corresponded closely with the sum of the UQ and UC contents of the dried yeast (Tables 1 and 2).

Qualitative results obtained by Dr. J. Green[8] on the same sample of fresh yeast agree with this finding.

It is clear from Table 2 that there has been no significant destruction of ergosterol or ubiquinone, and only extremely slight formation (if any) of ubichromenol during laboratory drying of the fresh yeast.

Ten experiments have been carried out on the effect of various treatments of yeast on the minor lipid constituents. Freeze-drying alone had no detectable effect, nor did storage for one week at

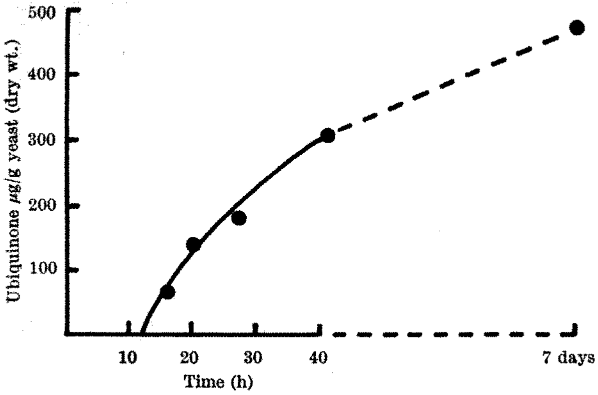

Fig. 2. Variation of the ubiquinone content with the growth period of *Torula* yeast

room temperature. Freeze-drying, followed by heating at 90° for periods up to 6 h, effected no appreciable loss of ergosterol or ubiquinone and no significant increase in ubichromenol. The most damaging treatment was to heat the yeast for 3 h at 80°–90° after spreading it out in a thin layer. This was harmful to ergosterol and to ubiquinone, but it did not raise the ubichromenol content. In fact, no treatment applied brought about more than a minimal increase in ubichromenol.

As a result of numerous trial experiments, it was found that the yeast could be grown satisfactorily in 250-ml. Erlenmeyer flasks on a shaker at 37°. The medium contained 5 per cent glucose, 1 per cent mycological peptone and the usual inorganic salts. The *p*H was maintained at 5·2 by potassium citrate buffer. By growing in 100 ml. medium for 3 days, a yield of 1·56 g (dry wt.) of yeast containing 300 μg/g (dry wt.) of ubiquinone was obtained. When ammonium sulphate was used as nitrogen source the yield of ubiquinone dropped to 112 μg/g dry wt., but this was boosted to 188 μg/g dry wt. by putting the glucose concentration up to 10 per cent although only 25 per cent of the sugar had been metabolized. When ammonium sulphate was replaced by 1 per cent leucine the yield of ubiquinone was restored to 300 μg/g dry wt., but less yeast (1·06 g) was produced.

Larger amounts of yeast could be grown in 1-litre medium in 3-litre flasks. These were aerated by attaching to a filter pump and sucking air through sintered glass distributors in the medium. As shown in Fig. 2, the yield of ubiquinone increased rapidly with time during the first 2 days, but then the rate of increase slowed down. Increase in aeration also increased the yield, but excessive frothing occurred.

Despite the great variations in yield of ubiquinone produced by these changes in conditions, on no occasion was ubichromenol found to be present.

The simplest explanation of the analytical data presented is that ubichromenol isolated from commercially dried *Torula* yeast is formed from ubiquinone during factory drying or storage of the yeast. It was not possible to reproduce the critical conditions for this conversion in the laboratory. Such an explanation presents two problems. In the first place, the ubichromenol so produced was optically active, and secondly, the conversion was extremely efficient. The optical activity could be explained by assuming that in the yeast cell ubiquinone is adsorbed on, or complexed with, protein or other material in some stereospecific manner such that ring closure during subsequent treatment to form ubichromenol can occur in only one of the two possible arrangements. An alternative hypothesis is that some optically active compound in the yeast cells can give rise to either ubiquinone or ubichromenol, depending on the treatment to which the cell is subjected. An attempt is being made to resolve the problem.

Natural Occurrence of Ubichromenol

All procedures previously used for the isolation or analytical determination of ubichromenol have involved saponification and/or chromatographic separation on alumina. Since both these steps have been shown to cause, under certain conditions, isomerization of ubiquinone to ubichromenol[1,2], doubts have been raised about the natural occurrence of ubichromenol. However, using a method of assay that had been shown to minimize the possibility of such isomerization, Diplock *et al.*[3] found a high concentration of ubichromenol$_7$ and ubichromenol$_9$ in dried *Torula* yeast. The presence of large amounts of ubichromenol and the fairly low level of fat in this yeast make it an attractive starting material for the isolation of ubichromenol by unequivocal procedures.

Dried *Torula* yeast (American type *B*; 1 kg) was treated with iso-octane (1 litre) with occasional shaking and left to settle. The supernatant liquid was removed and fresh iso-octane added. The procedure was repeated until about 2·5 litres of extract was obtained. After filtration, evaporation under reduced pressure yielded a brown oil (9 g) which gave a positive Emmerie and Engel reaction. The oil was extracted with boiling acetone (5 × 50 ml.) and the combined extract was reduced in volume (100 ml.), cooled to – 60° C and filtered. The volume of the filtrate was reduced to 50 ml. and the process repeated. Evaporation of the filtrate gave an oil (0·85 g) that was examined by paper chromatography without further purification. In the reversed-phase system (paraffin–95 per cent ethanol) four bands were observed, two of which (R_F 0·52 and 0·30) corresponded to ubiquinone$_7$ and ubiquinone$_9$. The other two substances (R_F 0·66 and R_F 0·42) were chromatographically identical with ubichromenol$_7$ and ubichromenol$_9$, gave a positive Emmerie and Engel reaction, and possessed a typical chromenol ultraviolet spectrum ($\lambda\lambda_{max}$ 273, 280 and 330 mμ).

An attempt was made to purify the extract further by removal of volatile constituents at 180° under molecular distillation conditions, but this led to a decrease in ubiquinone and an increase in ubichromenol. A model experiment with pure ubiquinone$_6$ confirmed that conversion into ubichromenol occurred at 180° at 0·1 mm. After being heated for 5 h, the product was examined by paper chromatography under nitrogen (paraffin–85 per cent ethanol system) and found to contain ubiquinol$_6$ (R_F 0·79), ubichromenol$_6$ (R_F 0·56), and unchanged ubiquinone$_6$ (R_F 0·38). The structure of the ubichromenol was confirmed by its ultra-violet spectrum. Ubichromanol was not detected. Although, in subsequent experiments, it was shown that isomerization did not occur at an appreciable rate at temperatures below 150° (such as are used for the commercial drying of *Torula* yeast), it was considered possible that the ubichromenols in the dried yeast might have been formed at some stage after collecting. To examine this, a sample of compressed *Torula* yeast cake was obtained from Wisconsin and, after saponification by the method of Laidman *et al.*[4], the non-saponifiable extract was examined in the paraffin–95 per cent ethanol system. Ubichromenol was not detected, but the ubiquinone concentration (on a dry wt. basis) was higher than that normally found in the commercially dried *Torula* yeast[3]. When samples of the compressed yeast were dried at 150° for several minutes in the laboratory, ubichromenol was not formed. These experiments support the suggestion that ubiquinone is converted to ubichromenol at some stage after gathering of the fresh yeast but that some factor other than heat is necessary. However, this suggestion must be reconciled with the observation of Morton and Hemming[5] that the ubichromenol$_7$ isolated from dried *Torula* yeast is optically active.

In order to clarify further the situation with regard to ubichromenol in animal tissues, the procedure described here was applied to rat liver, taken from animals deficient in vitamin E. The liver (50 g) was extracted as previously described by Edwin *et al.*[6]. The dry extract (2·7 g) was re-extracted with boiling acetone (4 × 25 ml.) and the combined extract was reduced in volume (50 ml.), cooled to $-60°$ C and filtered. Evaporation of the yellow filtrate under reduced pressure gave an oil which was extracted into light petroleum. The soluble portion (0·3 g) was strongly reducing, even at this stage, but could not be chromatographed directly in the reversed-phase system without being purified further by thin layer chromatography on 'Kieselgel *G*' plates, using benzene for development. Under these conditions, a partial separation of ubichromenol (R_F 0·3) and ubiquinone (R_F 0·25) was achieved. The ubichromenol fraction was extracted with ether and, when examined in the reversed-phase system (paraffin–95 per cent ethanol), migrated to the same position as authentic ubichromenol$_9$ (R_F 0·33) and gave a positive Emmerie and Engel reaction and a typical chromenol ultra-violet spectrum. Although chromatography of pure ubiquinones on 'Kieselgel *G*' plates leads to slight, just detectable, isomerization to ubichromenols, we regard it as unlikely that this could account for the quantity of ubichromenol$_9$ (30 μg/g) observed in this rat liver.

We thank the Lake States Yeast Corp., Rhinelander, Wisconsin, for generosity in providing samples of *Torula* yeast.

DISTRIBUTION OF RADIOACTIVE SELENIUM IN MICE

By G. B. JONES and K. O. GODWIN

C.S.I.R.O. Division of Biochemistry and General Nutrition, University of Adelaide

In the course of experimental studies of the nutritional importance of traces of selenium, the distribution of radioactive selenium within the tissues of mice was investigated.

Selenium, tagged with selenium-75, was introduced into lucerne (*Medicago sativa* L.) by growing the plants in a nutrient solution containing $Na_2{}^{75}SeO_3$. Examination of protein extracted from the leaves indicated that most of the selenium became concentrated in the leaf-protein fraction. These lucerne leaves were incorporated in the rations fed to mice, for periods up to 7 days; the daily intake of selenium from this source was 2 μg selenium containing 0·1 μc. selenium-75. Thus, the concentration of selenium was within the range usually present in natural foodstuffs.

After the feeding period the mice were anæsthetized, perfused via the left ventricle with buffered formalin; the organs were then removed, weighed and their radioactivity estimated in a well-type scintillation counter. Autoradiographs (Figs. 1–5) were made with Kodak *AR* 10 stripping film closely superimposed on histological sections.

Table 1. Localization of Radioactivity in the Tissues of Mice Fed Lucerne labelled with Selenium-75

	Score*

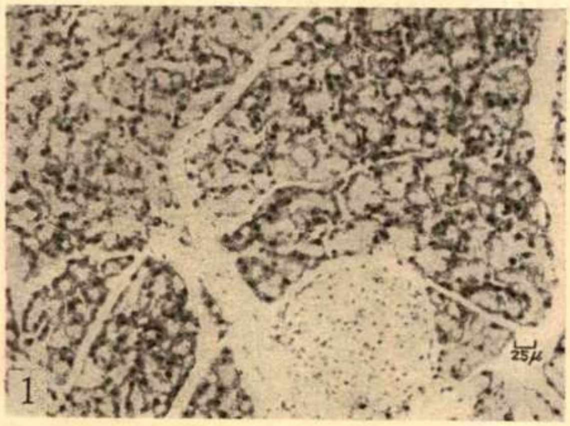
† Tissue not examined.

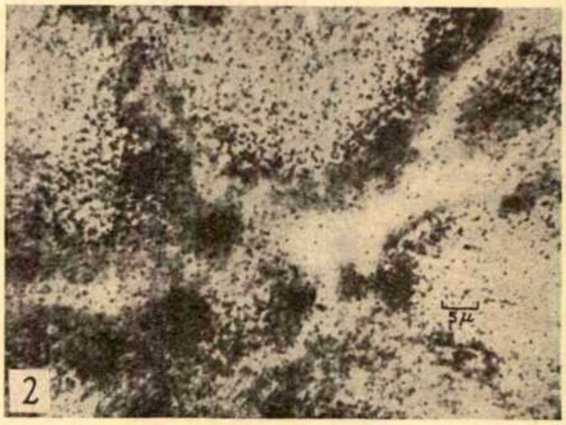
‡ Diseased pancreas.

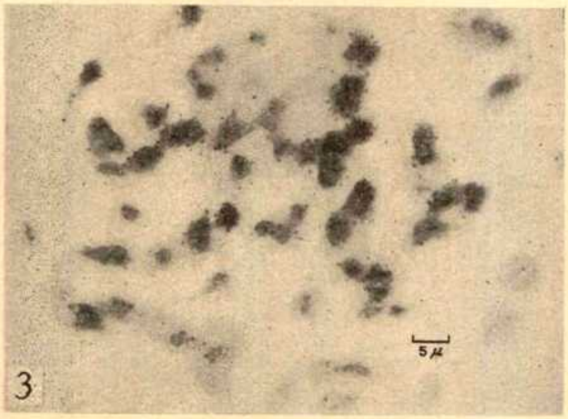
In terms of activity per unit wet weight of the organs removed at autopsy, the concentrations of selenium-75 ranged in the following order : kidney > liver > endocrine glands > pancreas ≫ lung > heart > spleen > brain. The concentrations of selenium-75 accumulated within these organs fell into two distinct groups, being appreciably higher in the first four than in the second four.

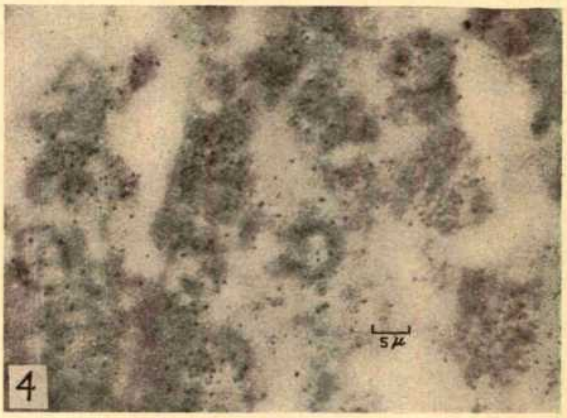
The autoradiographs (Figs. 1–5) indicated a discrete localization of selenium-75 within the cell nuclei. This was a consistent finding in all tissues examined except cardiac muscle, skeletal muscle and bone. In Table 1 a score has been recorded for each tissue, based on the degree of localization of activity as revealed by the autoradiographs. Judged from autoradiography, the greatest accumulation of selenium-75 occurred in the acinar tissue of the pancreas, and this was followed closely by the extent of the accumulation in the kidney, liver, adrenal, pituitary and thyroid. This would suggest a differential loss of selenium-75 complexes during histological processing.

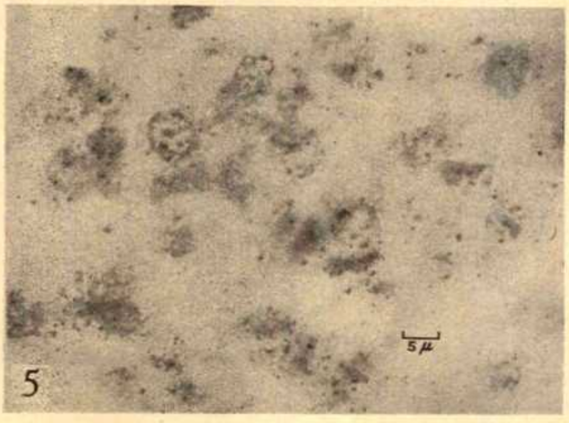
In another experiment, individuals from the litter of a lactating mouse, fed in the way described here, were examined at intervals for selenium-75. Radioactivity was detected in the baby mice 4 h after their dam had ingested the ration containing the lucerne labelled with selenium-75, and was continuously transferred in the milk at a steady level during the subsequent 6 h. The rapid transfer of selenium, when in organic combination of the sort present in the lucerne that was fed, suggests that selenium is











Figs. 1–5. Autoradiographs of sections of organs from mice that had ingested lucerne labelled with selenium-75

(1) Pancreas; unstained; low power (× 10 objective). The architecture of the organ is clearly defined by localization of selenium-75. The concentration in the islet of Langerhans (lower right) is markedly less than in the acinar cells

(2) Pancreas; unstained; high power (1/12 in. oil immersion objective). Acini in same section as Fig. 1. Radioactivity is preferentially associated with the nuclei of the acinar cells

(3) Kidney; high power (1/12 in. oil immersion objective), showing a glomerulus where radioactivity is characteristically concentrated over the nuclei

(4) Liver; high power (1/12 in. oil immersion objective). Note. The radioactivity is more generalized but relatively more highly concentrated in the nuclei

(5) Adrenal, zona glomerulosa; high power (1/12 in. oil immersion objective). Radioactivity occurs in zona fasciculata and zona reticulosa to about the same degree. There was little activity in the medulla

All sections were exposed for identical time on stripping film, Kodak *AR*.10. All illustrations have been reduced to three-quarters of original photograph readily metabolized, and that selenium-containing compounds are normal constituents of milk.

The considerable attention now being given to the function of selenium in animal tissues reveals that the liver and kidney are sites of comparatively intense selenium metabolism. Evidence from the autoradiographic studies reported here, and from the distribution of radioactivity on a weight basis, shows that the pancreas may also be of considerable importance in selenium metabolism, and that the endocrine glands are sites of relatively intense activity.

Localization of the isotope within the nuclei of the cells of most tissues suggests that selenium plays a functional part in the nucleus. Necrotic changes in the liver resulting from selenium deficiency in the rat[1] might thus originate in functional disorder of the nucleus, leading to its degeneration, thence to complete cell necrosis.

The findings recorded here are part of an investigation that will be published in detail elsewhere.

We thank Dr. H. R. Marston for his advice.

TWO-DIMENSIONAL ELECTROPHORESIS OF PSEUDOCHOLINESTERASE COMPONENTS IN NORMAL HUMAN SERUM

By PROF. H. HARRIS, D. A. HOPKINSON and E. B. ROBSON

Medical Research Council Human Biochemical Genetics Research Unit, Department of Biochemistry, King's College, London

AUGUSTINSSON[1,2] showed, by electrophoresis in cellulose columns, that the cholinesterase activity of human serum could be separated from the arylesterase activity. After electrophoresis at *p*H 8·4 serum cholinesterase activity was found in the α_2-β-globulin area while the arylesterase activity was found in a position similar to that of serum albumin. Similar separations had been obtained using filter paper electrophoresis[3,4]. With starch-gel electrophoresis, however, a more complex pattern of esterase components may be observed[5-10]. In particular, the findings suggest that serum cholinesterase activity is probably made up of several electrophoretically distinguishable components. In the present investigation we have attempted to define the electrophoretic behaviour of these components more precisely by using the technique of two-dimensional electrophoresis[11] which combines both kinds of separation referred to here.

Electrophoresis was carried out first in filter paper using barbitone buffer (*p*H 8·6) and then in starch gel using the discontinuous buffer system of Poulik[12]. The substrates used to detect and differentiate between the various zones of esterase activity were α-naphthylacetate, β-naphthylacetate, β-carbonaphthoxycholine, and *o*-nitrophenylbutyrate. α-naphthylacetate, β-carbonaphthoxycholine and *o*-nitrophenylbutyrate have been shown to be hydrolysed very much more readily by serum cholinesterase than by arylesterase[13-15]. β-Naphthylacetate[13], however, is hydrolysed by both enzymes at significant rates. These enzymes may also be differentiated in terms of their response to various inhibitors and activators. In the present investigations we used physostigmine (10^{-5} M), tetraethyl pyrophosphate (TEPP) (10^{-6} M), ethylenediamine tetraacetic acid (EDTA) (10^{-3} M) and Ca^{++} (10^{-3} M) for this purpose. Both physostigmine and TEPP in low concentrations are known to inhibit serum cholinesterase activity but not to affect arylesterase while EDTA inhibits and Ca^{++} activates arylesterase[4,16-19].

Fig. 1 illustrates the main esterase zones distinguishable after electrophoresis of 15 µl. of fresh adult serum using α-naphthylacetate as substrate. Four of the zones (C_1, C_2, C_3 and C_4) showed properties characteristic of serum cholinesterase activity. They were also detected with β-naphthylacetate, β-carbonaphthoxycholine, and *o*-nitrophenylbutyrate, and they were completely inhibited by physostigmine and TEPP. The activity in these zones was, however, unaffected by EDTA or Ca^{++} in the concentrations used here. A fifth zone (*A*), obtained with α-naphthylacetate, was also found with β-naphthylacetate and *o*-nitrophenylbutyrate, but not with β-carbonaphthoxycholine. It was not affected by physostigmine, TEPP, EDTA or Ca^{++}. It does not, therefore, appear to represent either serum cholinesterase activity or arylesterase activity. This zone (*A*) was found to be co-extensive with the area occupied by serum albumin, and it may represent the thermostable albumin esterase reported by Wilde and Kekwick[20]. Its close association with albumin was confirmed by the demonstration of two distinct zones of esterase activity corresponding with the two albumin zones found in cases of bisalbuminæmia.

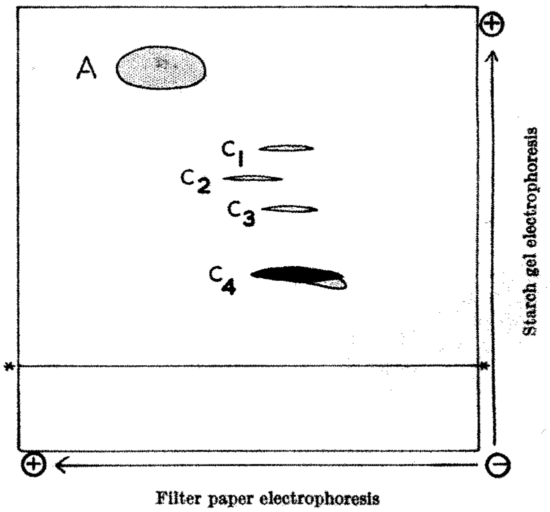

Fig. 1. Diagram of the main esterase zones after two-dimensional filter paper/starch-gel electrophoretic separation of 15 µl. of normal human serum

After 15 min incubation in 50 ml. 0·2 M phosphate buffer, *p*H 7·1, the following mixture was added to the sliced gel: 25 ml. phosphate buffer, 0·5 ml. 1 per cent α-naphthyl acetate in 50 per cent aqueous acetone, 10 mg Fast Red *TR* salt (Edward Gurr) *——*, line of insertion of filter paper in starch gel

Of the four zones, C_1, C_2, C_3 and C_4, which appear to be components of serum cholinesterase, one, C_4, was always considerably more intense than the others, and presumably accounts for most of the cholinesterase activity in normal serum. Although all four components migrated in the paper electrophoresis dimension in the α_2-β-globulin region, it is of interest to note that one of these components (C_2) had a significantly greater mobility in this dimension than the other three. Svensmark[21,22] has demonstrated, using paper electrophoresis, that the treatment of serum with neuraminidase results in a marked reduction in the mobility of the zone of serum cholinesterase activity, presumably because of the removal of sialic acid residues from the molecule. The four components, C_1, C_2, C_3 and C_4, have been observed to show this effect. The reduction in mobility in the paper electrophoresis dimension was paralleled by a similar reduction in mobility in the starch-gel dimension. Neuraminidase appeared to affect all four components in a similar manner and, using varying concentrations of neuraminidase and different periods of incubation, it was shown that the change of mobility was gradual. Zone *A* was not affected by neuraminidase.

A further zone of esterase activity with properties of serum cholinesterase could often be detected in trace amounts in adult serum. In the new-born (cord serum), however, this zone was very much more prominent (Fig. 2*a*). In cord serum it occurred together with components C_1, C_2, C_3 and C_4 described here, and appeared to account for about 15–30 per cent of the total serum cholinesterase activity as judged by the intensity of staining. This zone was also observed in seven sera obtained from human fœtuses (8–10 cm long), and in each case formed a substantial fraction of the serum cholinesterase activity present. A characteristic feature of this 'fœtal' serum cholinesterase zone was that it was obliquely orientated in the two-dimensional zymogram, in marked contrast to the zones C_1, C_2, C_3 and C_4 which were always horizontal. This finding suggests that the 'fœtal' zone is heterogeneous, the upper end of the zone consisting of enzyme molecules with a relatively greater mobility both in filter paper and in starch gel than those at the lower end. It was observed that a zone very similar in appearance to this 'fœtal' zone occurred in the very early stages of the modification of zone C_4 of adult serum by neuraminidase. It is possible, therefore, that the 'fœtal' zone may be due to the synthesis of serum cholinesterase molecules lacking their full complement of sialic acid residues, or to the partial removal of sialic acid residues after complete synthesis. Its occurrence is probably not due to the presence of neuraminidase activity in cord serum because incubation of the serum failed to produce further changes. Furthermore, there was always a clear zone of unchanged C_4 in cord or fœtal serum which was not present when adult C_4 was treated with neuraminidase to a sufficient degree to result in the formation of a zone resembling the 'fœtal' zone.

In a survey of sera from 300 randomly selected adult individuals 14 were observed to have an extra zone with the properties of serum cholinesterase (Fig. 2*b*). This zone had a slightly lower mobility than the main zone C_4 both in filter paper and in starch-gel electrophoresis. Among the individuals in whom it was found it was repeatedly detected in further serum samples. Thus it appears to be a constant individual characteristic. Furthermore, family studies showed that there was a much higher incidence of this peculiarity among the relatives of individuals showing it than in the general population. This suggests that it is genetically determined. Two typical pedigrees showing the segregation of this character are shown in Fig. 3. These and other family studies indicate that individuals possessing the extra zone are probably heterozygous for a relatively uncommon gene which determines the presence of this component. As it was not found possible, however, to detect the zone in all presumptive heterozygotes, the genetics of the peculiarity may be more complex. The occurrence of this variant was found to be independent of sex and age. So far it has not been found in association with other types of serum cholinesterase variants which may be detected by inhibition studies[23,24]. A more detailed account of the genetics of this peculiarity will be given elsewhere.

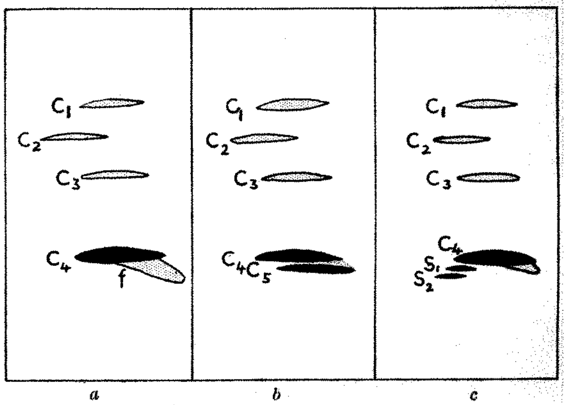

Fig. 2. Diagram showing three variations on the normal esterase pattern. Only that section of the gel containing material from the α–β area on paper electrophoresis is included
a, Cord blood—component *f*; *b*, genetically determined variant C_5; *c*, storage bands S_1 and S_2

In serum or plasma two further serum cholinesterase zones, S_1 and S_2, were observed (Fig. 2*c*). S_1 could be detected in all the samples after about ten days storage either at + 4° C or − 7° C. It migrated slightly faster than C_4 in the filter paper dimension, but slower in the starch-gel dimension. S_2 took longer to appear. Its mobility in filter paper was slightly greater than that of S_1, and its mobility in starch gel slightly less. On prolonged storage the intensity of both these zones increased. As it was accompanied by some decrease in the intensity of C_4 this suggests that it was from the C_4 zone that the two new zones appearing on storage were derived. S_1 and S_2 may be confused with the variant C_5 if the serum is only examined in starch gel in one dimension. However, in the two-dimensional system they are readily distinguished by their relative positions in relation to the main zone C_4.

Using β-naphthylacetate as substrate, and tetrazotized *o*-dianisidine as coupling reagent, two further zones of esterase activity may be detected and can be distinguished from serum cholinesterase by their properties. One of these zones migrates in paper electrophoresis with about the same mobility as serum albumin, but in starch gel it has a mobility similar to that of zones C_1, C_2 and C_3. It is a diffuse zone probably consisting of two or three separate components which, however, could not be sharply distinguished by the methods used here. It was not detected with α-naphthylacetate or inhibited by physostigmine or TEPP. The activity was, however,

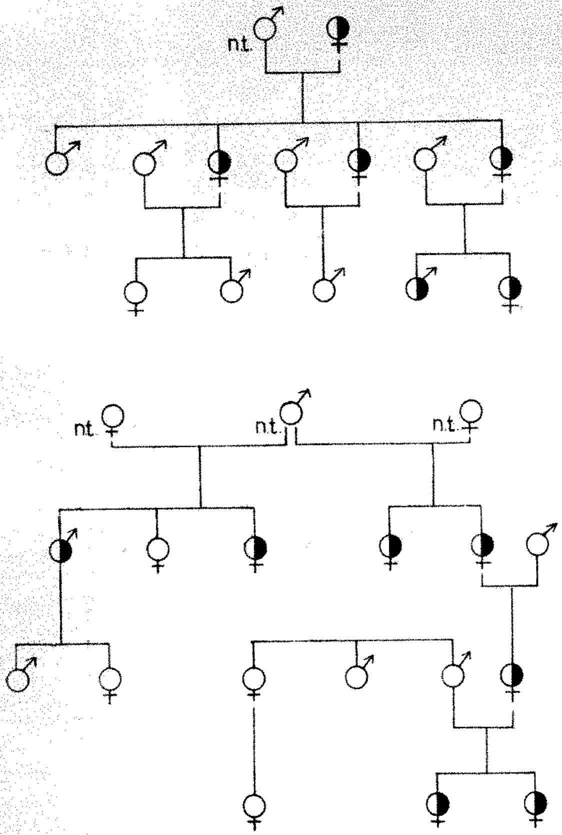

Fig. 3. Pedigrees of two families in which the esterase variant C_5 is segregating
◑, C_5 present; ○, C_5 absent; *n.t.*, not tested

increased by the addition of Ca^{++}, and inhibited by EDTA. This zone presumably represents arylesterase.

The second zone detected with β-naphthylacetate had different properties. It moved more slowly both in paper and in starch-gel electrophoresis than any of the other esterase components, and it appeared to be in the position occupied by β-lipoprotein, as detected either with lipid or with protein stains. Minor variations from serum to serum in the mobility of β-lipoprotein have been observed in starch gel electrophoresis, and these are exactly paralleled by variations in mobility of this zone. Furthermore, in certain rare sera containing two β-lipoprotein components, two corresponding zones were observed. The zone was not affected by EDTA, TEPP, physostigmine or Ca^{++}. Esterase activity associated with β-lipoprotein has been previously reported[25]. However, we have found that a similar zone can be obtained if β-naphthol itself is applied to the gel instead of β-naphthylacetate. It is possible, therefore, that in the experimental system used here any free β-naphthol arising from non-enzymatic hydrolysis may be specifically adsorbed on to β-lipoprotein and so contribute to the zone observed when β-naphthylacetate is used as substrate.

INDUCTION OF TOLERANCE OF SKIN HOMOGRAFTS IN IMMUNOLOGICALLY COMPETENT MICE

By Dr. L. BRENT* and Dr. G. GOWLAND*
Department of Zoology, University College, London

THAT unresponsiveness to skin homografts can be brought about across a 'strong' histocompatibility barrier (the *H*-2 locus in mice) was demonstrated by Shapiro *et al.*[1], who repeatedly injected the skin graft recipients with large doses of viable cells from the skin donor strain. The experiments reported here are also concerned with the immunological consequences arising from the injection of mice with allogeneic (= homologous) cells either on a single occasion or given over a prolonged period of time. They confirm the observation of Shapiro *et al.*, and they provide both qualitative and quantitative evidence that this kind of unresponsiveness is closely similar to, if not identical with, tolerance induced in fœtal or neonatal life.

In most of our experiments (*CBA* × *A*) hybrid (*H*-2*k*) spleen cells were injected into *A* strain (*H*-2*a*) mice; but in certain experiments the strain combinations were (*CBA* × *A*) hybrid → *CBA* or *CBA* → *C3H*. Whereas in the first two of these combinations donor and recipient strains differ at the *H*-2 histocompatibility locus, this is not true for the *CBA* and *C3H* strains, and for this reason the use of F_1 hybrid cells to avoid graft-versus-host reactions was not necessary in this strain combination. Unless otherwise stated, all cells were administered intravenously in the tail, and skin-grafting was carried out according to the technique of Billingham and Medawar[2]. The method of intravenous injection of 'adolescent' mice, the preparation of cell suspensions and other experimental techniques have been described elsewhere[3].

---

* Present address: Division of Experimental Biology, National Institute for Medical Research, Mill Hill, London, N.W.7.

Although some of the recipients were fully adult, most of the mice began their pre-treatment as soon as 13 days after birth; at this time they are immunologically competent but not far removed from that post-natal period in which it is possible to induce tolerance by conventional means, that is, by a single injection of allogeneic cells[4]. The experiments involving (*CBA* × *A*) hybrid and *A* strain mice were based on a weight-adjusted dose of 5×10^6 spleen cells/g because this is the dose which, in new-born *A* strain mice, is sufficient and necessary to establish tolerance in all recipients[4] (Fig. 1). On the other hand, when using *CBA* mice as donors and *C3H* mice as recipients the corresponding figure was found to be as low as $0{\cdot}15 \times 10^6$ cells/g, and this was therefore adopted as the weight-adjusted dose for this strain combination. The 30-fold difference in weight-adjusted dose is in some sense a measure of the strength of the *H*-2 locus compared with other histocompatibility loci.

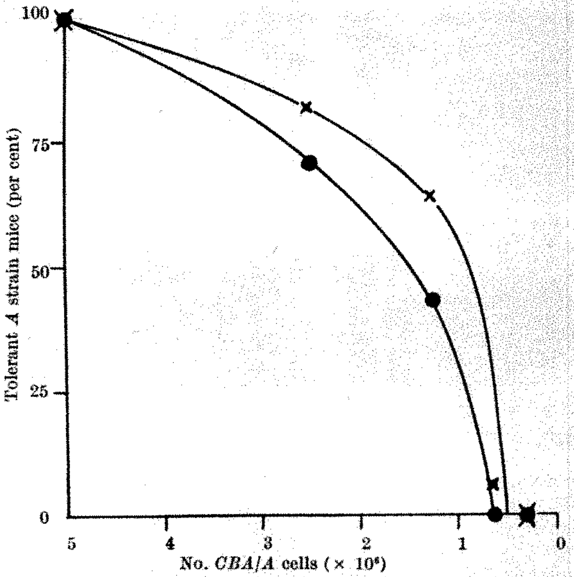

Fig. 1. Antigen dose (in the form of *CBA* × *A* hybrid spleen cells) and induction of tolerance in new-born *A* strain mice ×—×, (*CBA* × *A*) hybrid skin grafts surviving at 2 × median survival times of controls; ●—●, (*CBA* × *A*) hybrid skin grafts surviving at 5 × median survival time of controls

Our previous finding that, following a single intravenous injection of multiples of the weight-adjusted dose, 13-day-old mice do not become unresponsive to *H*-2 incompatible skin grafts[4] is supported by the results given in Table 1, lines 1–5. Far from developing unresponsiveness the mice were again weakly sensitized. (Owing to the fact that the recipients were skin-grafted almost at once it can be safely assumed that our previous results on these lines were not distorted by the interval of several weeks between injection of cells and skin-grafting.) Very similar results were obtained when *C3H* mice were injected with up to 20 times the weight-adjusted dose of *CBA* spleen cells (Table 1, lines 6–9). Regardless of whether donor and recipient strains differed at the *H*-2 locus the lower cell doses were again consistently more efficacious in sensitizing than were the higher doses, which failed to produce any significant deviation from the median survival time of the control grafts. So far as they go, the results obtained with *CBA* and *C3H* strains are in general agreement with the work of McKhann[5], who has shown that in *H*-2 compatible coisogenic *C57Bl* strains 1 or 5×10^6 cells injected intraperitoneally into adult mice sensitize, 50×10^6 cells fail to sensitize, and 200×10^6 cells induce tolerance in at least half the recipients.

Quite different results were obtained when, beginning on the thirteenth day after birth, *A* strain mice were repeatedly injected with (*CBA* × *A*) hybrid cells. The cells were administered intravenously every third or fourth day, and the recipients were grafted with hybrid skin on the day of the last injection. Following 7 injections the median survival time of the grafts was 30 days (Table 2, lines 1 and

Table 1. INTRAVENOUS INJECTION OF SINGLE DOSE OF ALLOGENEIC SPLEEN CELLS INTO FULLY ADULT RECIPIENTS

* Skin-grafted 3½ weeks after last injection.
† Presensitized by intraperitoneal injection of 5×10^6 (*CBA* × *A*) hybrid cells when 7 days old.
‡ Injected alternately by these two routes; first injection intraperitoneal (i/p).

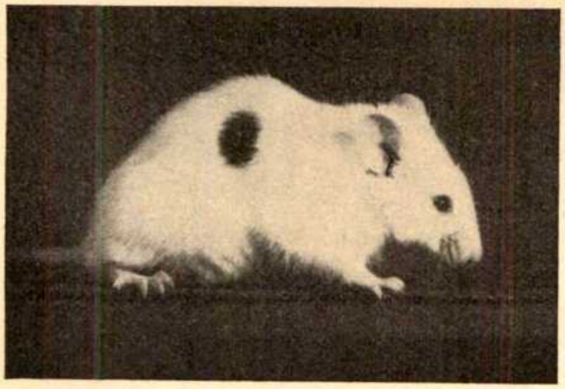

Fig. 2. Illustrating *A* strain mouse carrying a (*CBA* × *A*) hybrid skin graft 3 months after transplantation. Unresponsiveness was induced by twelve injections of the weight-adjusted dose, beginning on the thirteenth day of life

5) and 5/20 grafts survived in very good condition, with more or less normal hair growth, for at least 65 days (= 5 × median survival time of the control grafts). When the number of injections was 12 the median survival time well exceeded 70 days (Table 2, line 6) and 17/28 grafts survived in good condition (Fig. 2) until unresponsiveness was broken experimentally by the transfer of normal or pre-sensitized *A* strain lymph node cells or until the animals were killed so that their spleens could be used for chimera tests. That this unresponsiveness was not due to non-specific factors such as physiological stress was clearly shown by the normal survival times of grafts in control experiments in which 13-day-old *A* strain mice were subjected to exactly the same regimen of injections using syngeneic *A* strain cells (Table 2, lines 11 and 12).

Several other points arise from the results summarized in Table 2. (*a*) Pre-sensitization of the recipients by an intraperitoneal dose of 5×10^6 cells on the seventh day after birth did not appreciably prejudice the induction of unresponsiveness (line 8). This experiment could bear repetition with a more powerful sensitizing stimulus in the form of skin grafts. (*b*) An interval of 3½ weeks between the last injection and skin-grafting reduced the proportion of mice exhibiting some degree of unresponsiveness without significantly lowering the proportion of highly unresponsive mice (line 7). (*c*) When 13-day-old mice were injected 7 times intraperitoneally they were strongly sensitized (line 9). (*d*) Alternation between intraperitoneal and intravenous routes, commencing with the former, led to a slight shortening of the median survival time (line 10) compared with that of the control grafts; but the degree of sensitization to be read into this was nowhere near as great as that produced by intraperitoneal injections alone. (*e*) There was evidence that the development of unresponsiveness was progressive and that before unresponsiveness was finally established the mice went through a transient period of sensitization: 1 or 2 injections of the weight-adjusted dose weakly sensitized (lines 2 and 3), 4 injections raised the median survival time of the grafts just beyond that of the controls (line 4), and 7 injections resulted in a very substantial increase in the median survival time and the induction of a high degree of unresponsiveness in 25 per cent of the mice (line 5) (Fig. 3). There is, however, one qualification which must be made about these results, namely, that in the experiments summarized in lines 2–4 of Table 2 the mice were all skin-grafted 5 weeks after birth irrespective of the number of injections given, so that the interval between the last injection and grafting varied from 3 weeks (1 injection) to one week (4 injections), whereas in the long-term experiments (7 or 12 injections) the mice were grafted one day after the last injection. This variable was forced on us by the difficulty of skin-grafting very young mice, and we intend to eliminate it in future experiments with fully grown mice. The same shortcoming in experimental design prevents us from being absolutely certain that, just because antigen was continued to be administered in the long-term experiments, the development of sensitivity in the earlier stages was not blocked by excess antigen.

Experiments on the induction of tolerance by the repeated injection into adult animals of certain proteins also show that, prior to the development of tolerance, there is a phase in which antibodies are produced[6,7].

The properties of unresponsiveness are still being examined, but several conclusions can be stated here in bald terms (see also ref. 3). (1) As already indicated (Table 2, lines 11 and 12), unresponsiveness is not due to non-specific factors. Furthermore, like classical tolerance it is strain specific: five highly unresponsive mice promptly rejected *C*57 or *AU* skin grafts without deterioration of their long-established (*CBA* × *A*) hybrid grafts. It must, however, be borne in mind that, as in all specificity tests performed on mice which have become cellular chimeras (see later) as a result of the injection of allogeneic lymphoid cells, the rejection of third party grafts is likely to be influenced by the immunological reactivity of the donor cells. (2) Unresponsiveness can be broken experimentally by the transfer of normal or pre-sensitized lymph node cells syngeneic with the host. (3) There is no evidence from our experiments that *A* strain mice which accept (*CBA* × *A*) hybrid skin grafts form hæmagglutinating or cytotoxic antibodies. In view of the fact that this particular strain combination is a poor one so far as the production (or detection) of hæmagglutinins is concerned we are at present investigating the effect of injecting (*CBA* × *A*) hybrid cells into *CBA* hosts. (4) The unresponsive mice become cellular chimeras: by quantitative *in vivo* tests[3] it has been established that their spleens contain a proportion of donor cells and that this proportion is unlikely to exceed 5–10 per cent. These somewhat indirect tests are now being followed up by experiments utilizing *CBA* (*T*-6) chromosomally 'labelled' cells.

The foregoing properties are exactly those of immunological tolerance conferred on mice in fœtal or neonatal life[8,9], and it may be concluded that we are dealing here with the same phenomenon. Quantitatively the induction of tolerance in neonatal and immunologically competent mice is very different indeed: one requires one single weight-adjusted dose whereas the other cannot be brought about by as many as 10 or even 20 times the weight-adjusted dose if it is given on a single occasion. This difference is almost certainly due to the absence, or virtual absence, in the neonatal *A* strain mouse of immunologically competent cells—a conclusion which is amply supported by our investigations on the induction of tolerance in the first two weeks of life[4]. To overcome the barrier created by the presence of mature antibody-forming cells the cellular antigen must evidently be administered over a prolonged period, at least when donors and recipients differ at the *H*-2 locus. But our experiments do not, at

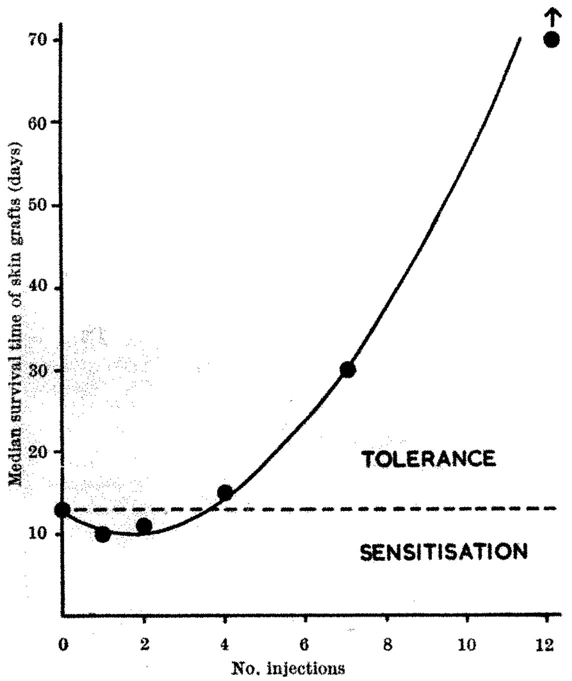

Fig. 3. The effect on the median survival times of (*CBA* × *A*) hybrid skin grafts transplanted to groups of mice injected from the thirteenth day of life, twice weekly, with weight-adjusted doses of hybrid spleen cells (Table 2, lines 1–6, and text)

present, permit us to make a statement on the nature of tolerance at a purely cellular level, that is, as to what happens when a cell becomes tolerant: our results could be equally well accommodated by the hypothesis of progressive paralysis of mature antibody-forming cells by excess antigen as by the hypothesis postulating the death of these cells by prolonged contact with antigen and the induction of tolerance in immature stem cells.

From our knowledge of the relationship between antigen dose and regimen of administration we predicted that it should be possible to induce tolerance by the repeated injection of cell doses which, when given just once to new-born mice, are inadequate for tolerance induction—provided that the course of injections is begun in neonatal life. $0{\cdot}5 \times 10^6$ cells/g (that is, 1/10 of the normal weight-adjusted dose) seemed a suitable dose (Fig. 1) and accordingly 18 *A* strain mice were injected with this dose of (*CBA* × *A*) hybrid spleen cells starting within 12 h of birth and continuing every third or fourth day. When the mice were grafted with hybrid skin 3 weeks after the last injection, 72 per cent showed some degree of tolerance and 50 per cent were fully tolerant in the sense that they grew normal crops of hair and survived for a minimum of 65 days (= 5 × median survival time of the control grafts). In mimicking the results of experiments with 13-day-old mice (Table 2, line 6) these results fulfilled our prediction, and they lend further weight to the contention that the difference between tolerance induction in new-born and immunologically competent mice is essentially a quantitative one. Since the degree of tolerance conferred in the first 5 weeks of life by 10 injections of 1/10 of the weight-adjusted dose is considerably inferior compared with the degree of tolerance induced by one weight-adjusted dose in new-born mice (Fig. 1) it is clear that, with increasing age, it is more difficult to establish tolerance even with a dose of cells based on the weight of the recipients. This would be explained if the increase in weight of young mice does not wholly reflect the increase in the number of immunologically competent cells—a point on which we have, at present, no precise information.

The results given in Table 1 (see also Brent and Gowland[4]) are different from those reported by Guttmann and Aust[10] and by Wigzell[11] who, respectively, found that the injection of a single large dose of *C3H*/*A* spleen cells into *C3H* adults, and of *CBA*/*A* cells into *A* strain adults, led to a striking prolongation of skin graft survival. Some of the cell doses used by us unsuccessfully were of the same order of magnitude. Guttmann and Aust tested their mice with very large skin grafts compared with those used in our experiments, and this might conceivably have influenced the outcome of their experiments. Genetic differences between sub-strains of *A*, *CBA* and *C3H* could also be an important contributory factor, especially in view of Wigzell's finding that skin transplanted from *A* strain donors maintained in the Karolinska Institute to *A* strain mice kept in our department were not accepted (personal communication). Unlike Wigzell[11] we have so far failed to demonstrate the presence of humoral antibodies in our tolerant mice.

The striking difference in results obtained with intravenous and intraperitoneal routes requires comment. We have yet to convince ourselves that this is due to a more efficient distribution of the cells rather than to a feature unique to the intravenous administration of antigen. The observation that alternation between the two routes does not lead to the induction of tolerance suggests that the latter explanation is the more plausible, and this question is now being investigated more fully.

The main conclusions to be drawn from our experiments are that unresponsiveness of skin homografts can be established in immunologically competent mice by the repeated injection of viable lymphoid cells; that the intravenous injection route is obligatory when attempts are made to overcome the barrier of the *H*-2 locus; that this unresponsiveness is almost certainly the same as immunological tolerance induced in fœtal or neonatal life with a single stimulus; and that the difficulties encountered when attempts are made to induce tolerance in post-natal life are intimately bound up with the increase in immunologically competent cells from birth onward.

We thank Dr. P. B. Medawar and Dr. H. A. Mitchison for their advice.

Note added in proof. We have now satisfied ourselves that immunologically mature (*CBA* × *A*) hybrid mice made tolerant, or partially tolerant, of *CBA* skin grafts do not possess hæmagglutinating antibodies, and that this cannot be due to *in vivo* absorption by donor strain cells.

INDUCTION, REVERSION AND EPITROPHISM OF FLAX GENOTROPHS

By DR. ALAN DURRANT

Department of Agricultural Botany, University of Wales, Aberystwyth, and Earhart Plant Research Laboratories, Biology Division, California Institute of Technology, Pasadena

EXPERIMENTS with many thousands of plants carried out over a period of nine years have shown that heritable changes are induced in flax plants of the variety Stormont Cirrus when they are supplied with different combinations of nitrogen, phosphorus and potassium, and when they are grown for at least the first five weeks in a heated greenhouse[1]. The original variety is a plastic genotroph which is changed into a large stable genotroph, or a small stable genotroph, depending on the nutrients supplied. The large stable genotroph is three or more times the weight of the small stable genotroph and both have remained unchanged in inheritance for seven generations irrespective of the fertilizers that have since been applied. Both behave as two distinct genetic types, giving equilinear inheritance in their reciprocal crosses and no transmission through their reciprocal grafts. The plastic genotroph is intermediate in weight, but taller than the other two, and all plants are highly uniform within each genotroph.

Studies have been made on the variation in the F_1 and F_2 of the reciprocal crosses between the large (L) and small (S) stable genotrophs. Table 1 gives the results of separate crossing experiments with different groups of parent plants carried out in different years at Aberystwyth. The F_2 was examined first and the coefficients of variation, which compensate for differences in the means, show that the variation in both reciprocal crosses is higher than within the individual parent crosses, suggesting genic segregation. On the other hand, there is a marked difference between the two reciprocal crosses, the $S \times L$ variation being higher than any of the other three types of cross. In addition, the same pattern of variation is obtained in the F_1 of these crosses, and in the F_1 of other crosses, in plant weight and plant height. The correlation between the F_1 and F_2 coefficients of variation of the four types of crosses is extremely high ($r = 0{\cdot}87$ for F_1 weight/F_2 weight; $r = 0{\cdot}97$ for F_1 height/F_2 weight). Genic segregation therefore is probably not the sole explanation for the increase in variation in the F_2 of the reciprocal crosses.

To check whether the F_2 variation was at least in part due to the variation in the F_1, five F_1 plants were selected from each of the four types of crosses, and F_2 families of five plants were grown from each in winter in a heated greenhouse. Table 2 shows that the positive correlation between F_1 plant weights and F_2 family means is virtually complete in the $S \times L$ cross, and high in the $L \times S$ cross, while the small amount of variation among the F_2 family means of each of the parent crosses is negatively correlated with the F_1 plant weights, a maternal relationship commonly occurring under winter conditions. There is, therefore, an immediate breakdown, or instability, in the F_1 of crosses between the two stable genotrophs producing to all appearances random, heritable variation, which presumably arises from the opposing nature of the factors or processes determining the two genotrophs, or the destruction of their delicate balance by chance metabolic variation. Since factors in addition to nutrition appear to be involved, the various forms may be referred to as 'epitrophs'. There is evidence from exploratory experiments at the Earhart Laboratories that the F_1 instability may be arrested if the F_1 plants are grown under certain conditions but it is not clear at present which are the relevant environmental factors.

The large genotroph used for these crosses was induced at Aberystwyth by applying nitrogen, phosphorus and potassium to the plastic genotroph, and the small by applying nitrogen and potassium, but taking into account soil fertility and soil inter-

actions, it was suspected that the balance of nitrogen and phosphorus was particularly important, nitrogen inducing the large genotroph and phosphorus the small. At the Earhart Laboratories nitrogen and phosphorus were added separately to different groups of plants of the plastic genotroph grown in a gravel and vermiculite mixture with dilute Hoagland's solution in different day/night temperature (°C) combinations. The progeny of the nitrogen and phosphorus treated plants were approximately equal in weight to the large and small genotrophs respectively when the treated parent plants were grown in 27/15 and 23/23 temperatures, progressively smaller induced changes occurring in 27/11, 27/7 and 31/7, and none in 19/11. This confirms the importance of the balance of nitrogen and phosphorus, in the absence of soil interactions, for the induction of changes transmitted to the first generation and also shows that high day and night temperatures are necessary. On the other hand, these changes were not inherited by the second generation grown at Aberystwyth so that there remain other unknown environmental factors. These impermanent changes are nevertheless of additional interest and are of some significance in view of the temperature requirements for partial reversion mentioned here.

At Aberystwyth the large and small genotrophs were grown under conditions giving a greater day/night temperature difference, maximum natural day length and maximum light intensity during the first five weeks of their growth, and the two following generations were grown under approximately similar conditions. By the third generation the difference in weight between the two genotrophs had practically vanished although other characteristic differences such as branching habit, leaf size and colour remained distinct. At the Earhart Laboratories the original large and small stable genotrophs were grown in day/night temperatures of 27/15 and 27/7 in 50 per cent Hoagland's solution, and the two following generations in all combinations of these temperatures as shown in Table 3, where the differences between the large and small genotrophs in the second generation are entered. The differences between the two sets of differences, one set for the second generation plants grown in 27/15, and the other for those grown in 27/7, in addition to assessing the responses in this generation, remove a large amount of extraneous maternal effects of the previous generation's treatments, and show that the difference between the large and small genotrophs grown consistently in 27/7 is greatly reduced compared with those grown consistently in 27/15. Those grown previously for one generation in each of the two temperature combinations show intermediate differences. This partial reversion is probably not permanent and appears from these and other observations to occur when parents and their progeny are grown consistently in the same environment of strongly contrasting day/night temperatures (27/7). In view of these results, the induction and transmission to the first generation of only small changes at 31/7 and 27/7 temperature combinations mentioned here are not unexpected.

Altogether there are here three classes of heritable change. Class I: changes which are maintained largely in those environments inducing them, that is, the partial, temporary reversion of the large and small genotrophs. Class II: the induction of the large and small stable genotrophs from the plastic genotroph. Class III: the heritable variation arising immediately in crosses between the large and small genotrophs. Classes II and III are almost certainly nuclear with the cytoplasm having a subsidiary role. It is not clear whether intermediate genotrophic forms induced by certain fertilizer and temperature treatments, or some of the epitrophs, are stable or transitional to the three genotrophs mentioned earlier, but it is notable that all the variation originates from the influence of the environment on a hitherto uniform variety of flax.

These results are more profitably discussed when other crossing experiments are completed. Numerous comparisons can be made with other forms of heritable change, cellular differentiation, paramutation and similar phenomena, but it is particularly interesting to note that the variation in Class III is strikingly similar to the variation reported by Sonneborn[2], Kimball[3], Nanney[4], and other workers, among caryonides of the unicellular organisms *Paramecium aurelia* and *Tetrahymena piriformis*, where exconjugants give rise to daughter cells of different mating types during successive mitotic divisions. Variation of this type may therefore be common and perhaps responsible for part of the variation normally ascribed to classical segregation and recombination.

Varieties of other crop plants, unlike flax varieties, have been bred for characters such as plant weight and seed yield[1], and they may be equivalent to the stable, rather than to the plastic, flax genotrophs, so that the probability of Class I changes occurring would be higher than those of Class II. One example is known ; Highkin[5] has reported that peas of two varieties deteriorate in size and vigour when grown for several generations in constant day/night temperatures, but are restored after two or three generations in a fluctuating day/night temperature. Speculatively, assuming similar metabolic changes to those in flax, the pea varieties could have arisen initially from plastic pea genotrophs grown at a reasonably high temperature with excess phosphorus—not improbable conditions. On the other hand, it may be simply a question of breeding.

It is probable that individuals in natural populations vary in their possession of heritable factors or processes which can be altered or stabilized by the environment. Mutation anywhere in the heredity material, or crossing between unlike individuals, may

Table 3. Differences (L–S) in Weight (g) between Large (L) and Small (S) Stable Genotrophs of the Second Generation descended from Parents and Grandparents grown in Different Combinations of Day/Night Temperatures (°C)

Parental generation temperature	27/15	27/15	27/7	27/7

Second generation grown in 27/15 (b)	10	16	9	15
Difference (a–b)	8	2	1	−5

stabilize some factors to give stable genotrophs, and break down others to give plastic genotrophs, the environment thereby directly altering the characteristics of a population, as distinct from its indirect action in natural selection. Although it is possible that heterozygous individuals in natural populations may be buffered to a greater extent against all three classes of heritable change, such changes may be widespread, and potent factors in biological evolution.

I thank Prof. George W. Beadle and Prof. Anton Lang for the opportunity to carry out some of these experiments in the Earhart Laboratories, California Institute of Technology.

BIOASSAY OF TRADE WASTES

By L. CARTER

Imperial Chemical Industries (Paints Division), Ltd., Research Laboratory, Brixham

DURING recent years river boards, with the co-operation of local authorities and industry, have done much to improve the condition of many rivers which are heavily polluted by sewage and industrial wastes. Standard methods of analysis have been developed, but there is a lack of information concerning the toxic effects of discharges of complex wastes on the plants and animals in natural waters. In particular, there appears to be a need of a quantitative method for the assessment of the toxicity to fish of trade wastes. Much work has been done on the subject; but so far all the methods have been prolonged and the interpretation of results leaves much to be desired.

A relatively simple and rapid method applicable both to field and laboratory investigations has been developed in this laboratory. A series of dilutions of a representative sample of effluent is prepared with water of similar composition to the natural water receiving the discharge. A glass bottle with a capacity of 2 l. is filled with each test solution, two fingerling brown trout are introduced and the containers are stoppered, avoiding air bubbles. The dissolved oxygen concentration in each solution is measured at the beginning of the experiment and on the death of the fish, using a portable dissolved oxygen meter which incorporates a dropping mercury electrode. It has been found that the residual oxygen concentration is moderately constant for a given batch of fish in clean water, but when harmful substances are present the residual oxygen concentrations are higher. Since the toxicity to fish of many compounds increases as the dissolved oxygen of the water falls toxicity is enhanced as the fish respires and consequently the survival period of the fish decreases.

Experimental results are presented in Fig. 1 which show that concentrations of cyanide down to 0·025 p.p.m. and copper down to 0·1 p.p.m. inhibit the uptake of oxygen by trout in the sealed containers during experiments of 300 min duration. Thus, compared with conventional bioassay, this method constitutes a more rapid and sensitive means of detecting these substances in low concentrations. For example, Herbert and Merken[1] found that the median survival period of rainbow trout was at least 10,000 min in water saturated with oxygen containing 0·05 p.p.m. of cyanide, and it is recorded in the annual report of the Water Pollution Laboratory for 1959[2] that the median survival period of rainbow trout is of the order of 1,000 min in aerated water containing 0·1 p.p.m. of copper.

The new technique has also been used for the bioassay of complex chemical wastes, and the results compare favourably with those obtained from a more conventional method of bioassay where fish were immersed in aerated solutions of effluent and their survival time noted. Concentrations of effluent which killed fish within 96 h in aerated waters also impaired the reduction of the oxygen concentration by trout in sealed containers within 300 minutes.

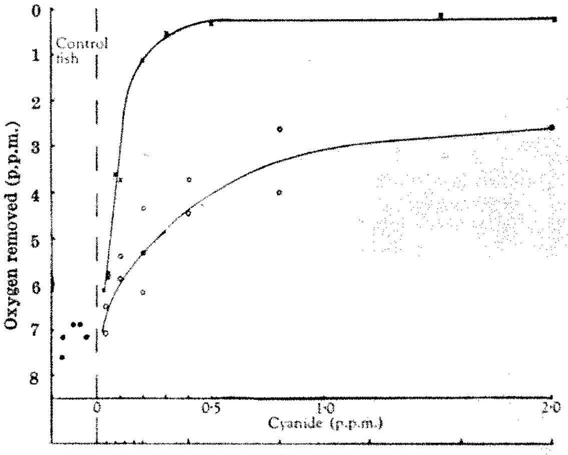

Fig. 1. Effect of cyanide (×) and copper (○) on the uptake of oxygen by brown trout

It is concluded that the technique permits the rapid detection of solutions containing low concentrations of copper and cyanide which are toxic to fish. It seems likely that the method might also be used to make rapid assessments of the toxicity to fish of complex trade wastes.

Where many effluents are discharged to a watercourse it would be advantageous to pinpoint the more toxic discharges at the site of their discharge. The new technique is particularly suitable for this type of investigation, as it is a rapid method and the apparatus is simple and portable. Investigations at the site of discharge would also avoid transporting samples to a central laboratory during which time the quality of the effluent might be altered by chemical reactions or biological activity.

LETTERS TO THE EDITOR

ASTRONOMY

A Corrugated Model for the Lunar Surface

We would like to suggest that a number of previously uncorrelated visual and infra-red lunar observations may be explained by assuming that the surface of the Moon has indentations the scale of which is too small to be resolved optically by terrestrial observations. For simplicity of argument, we consider the shape of the indentations to be as shown in Fig. 1. In addition, for the arguments given here to be rigorously true, the linear dimensions of the indentations must be appreciably greater than the parametric distance for thermal conduction during a lunar cycle (~ 3 cm).

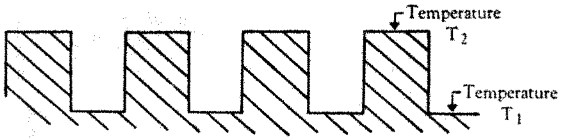

Fig. 1

It is clear from radiation considerations that during an eclipse the temperature T_1 of the bases of the indentations of our model vary very much less than will the temperature T_2 of the upper surfaces. Eclipse measurements[1,2] show a greater variation of effective temperature for regions close to the lunar limb than for regions at the centre of the lunar disk. This result is in agreement with the proposed model since radiation received from the lunar limb would come only from the top of the indentations, whereas that from the centre of the disk would consist of equal contributions from the base and top.

A similar argument may be applied to the results of observations of the effective temperature of the centre of the disk measured as a function of time throughout a complete lunar period[3,4]. With the model considered, the variation of temperature of the base of the indentations would be very much less than for a simple flat surface, for in addition to radiation considerations the bases of the indentations would receive solar radiation for only a small fraction of the Moon's period. The observed variation of effective temperature during lunation is less than that predicted from the application of the results of eclipse measurements to a simple plane surface, a result which would be expected from the model here proposed.

Infra-red measurements[1] show that when the sub-solar point is near the lunar limb (first and last quarters) its effective temperature is about 50° C lower than when it coincides with the centre of the lunar disk at full Moon. Previously, this effect has been attributed to the large-scale mountainous nature of the lunar surface, but an examination of lunar topography shows that the average lunar slope (~ 0·01 radian) is insufficient to account for the large effective temperature change, although such a change could well be accounted for by an indented model.

Finally, photometric measurements of radiation of wave-length 3000 Å–9000 Å show deviations of the Moon's surface from that of a simple diffuse reflector. In particular, at full Moon the radiation received from the lunar limbs is relatively greater than that expected from a diffusely reflecting sphere, while the sub-solar point appears considerably brighter than would be expected from observations of this point at other times during the lunar period. Models similar to that suggested here have, in fact, already been investigated both experimentally[5] and theoretically[6,7] and they have been found to give good agreement with lunar photometric measurements.

PHYSICS

Slicks on Lake Huron

While examining the movement and dispersion of groups of drift-bottles released simultaneously at Douglas Point, on Lake Huron, we came upon some pronounced 'slicks', well known to oceanographers. These can be recognized by eye as streaks of smooth water from which the capillary waves are absent and in which quantities of organic matter and other floating debris collect. There are apparently a number of possible mechanisms for the production of slicks, all leading to accumulation of surface material through confluence of the surface water layers, which sink at the slick, leaving any floating material to collect on the surface.

In our experiments a group of small cylindrical jars, 5 cm in diameter, 8 cm high, lids painted fluorescent yellow and weighted so that the lid floats level with the surface, were released from a boat, with the intention of following their dispersion by turbulent diffusion. In the initial phase the growth of the 'cloud' exhibited the typical features of 'relative' turbulent diffusion in that the rate of growth increased with the size of the cloud. This is in accordance with the observations of Richardson and Stommel[1] and the theory of Batchelor[2]. At some stage of this regular turbulent diffusion then the group would typically arrive at a slick and the bottles would re-collect along a line oriented at some angle against the original direction of mean drift. When this angle was not too far from 90°, the whole group became quite concentrated again, because the diffusion in a direction perpendicular to the direction of the mean drift was typically much less than along it. Afterwards, for a prolonged period, the bottles would remain in the slick spreading out along it but remaining in a narrow line (a slick is typically 1–2 m wide) and travelling along the slick with the local drift velocity. On some occasions the bottles remained in the slick for 5–6 h and apparently only left it when the entire slick disappeared in a change of wind. The slicks seemed to be most pronounced and permanent around a wind speed of 5 m.p.h., in May, before the development of the thermocline.

Surface temperature measurements in and near slicks invariably showed a temperature difference of 0·5°–2·0° C from one side to the other, often over a very short distance. On one occasion, when strong solar heating was present, the temperature at the centre of the slick was 1·0° C higher than on the warmer side. The surface temperatures measured in these observations were between 8·0° and 14·0° C. All the observations were carried out within 500 m from the shore in water 8–10 m deep.

A Superconducting Solenoid

Tests have been made recently on a superconducting solenoid constructed from what is believed to be the longest continuous length of niobium–zirconium alloy wire so far produced in the United Kingdom. An ingot of the alloy (75 at. per cent niobium, 25 at. per cent zirconium) was swaged and cold drawn to give approximately 320 feet of 0·010-in. diameter wire. 100 ft. of this was used to construct the coil, which is shown in the accompanying photograph. The insulation was provided by a single layer of silk wrapping round the wire and by sheets of 'Melinex' between the layers of the coil.

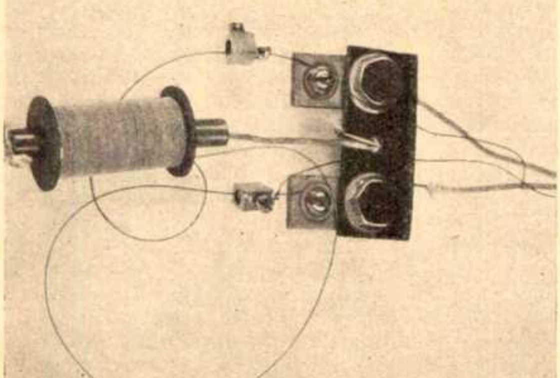

Fig. 1

The coil had the following characteristics: length of winding, 3 cm; internal diameter, 1 cm; external diameter, 1·6 cm; No. of turns, 992; maximum magnetic field, 382 gauss/amp.

A copper rod was inserted in the centre of the solenoid to absorb the energy released when the coil was driven normal (that is, became resistive). During operation the coil was immersed in liquid helium at 4·2° K.

The maximum current required to drive the wire normal was 23 amp; corresponding to a critical current density in the superconductor of $4 \cdot 5 \times 10^4$ amp/cm^2 and a maximum magnetic field at the centre of the solenoid of 8·8 kilogauss. No 'training' effect[1] was noted during repeated runs. This current density agrees with the values of $5–7 \times 10^4$ amp/cm^2 in a field of 10 kilogauss obtained by extrapolating data obtained by Berlincourt[2] for straight wire specimens of the same composition.

The work described here forms part of an extensive programme, initiated at the Nuclear Research Centre of C. A. Parsons and Co., Ltd., at the beginning of this year, to investigate the fabrication, properties and practical applications of superconductors. Pieces of the wire have been passed to Government and university laboratories for additional tests.

We thank the Directors of C. A. Parsons and Co., Ltd., for permission to publish this communication.

CRYSTALLOGRAPHY

Anomalous Extinction Effects in X-ray Reflexion by Crystals

It is commonly supposed that the effect of the presence of perfect blocks produces a decrease in the intensity of X-ray reflexion from a mosaic crystal. This phenomenon is therefore known by the name of extinction (primary or secondary extinction, according to the conditions of the experiment). However, it appears that this is not necessarily so, and that, under certain conditions, a perfect crystal can give an integrated reflexion which is larger than that of a mosaic crystal. In this case, one would not have an extinction, but an enhancement in the reflected intensity due to the deviation of the crystal from the ideally mosaic state. These results follow from the dynamical theory, in particular from the formulæ developed by Ramachandran[1], and have actually been verified in this laboratory using perfect and milky crystals of calcite as representatives of the two extreme limits of perfection.

As is well known[2], if the reflexion occurs from the surface of the crystal, then it can be shown that the integrated reflexion of a mosaic crystal is larger than that of a perfect crystal and is, in fact, the upper limit under different conditions for the latter. However, for an internal reflexion ('Laue case') the integrated reflexion for a perfect crystal can be much larger than that for a mosaic crystal, due to the occurrence of the Borrmann effect. Using the notation of Ramachandran[1] and considering a thickness for which $(\mu t/\gamma)$ is of the order of 5, the integrated reflexion of a symmetric internal reflexion from a perfect crystal in y-units can be represented by the approximate formula:

$$R_y^P = \frac{\pi}{2}\,\frac{1}{(2\pi\mu t\varepsilon K/\gamma)^{1/2}}\,e^{-\mu(1-K\varepsilon)t/\gamma}$$
$$= \text{constant} \times \frac{e^{-\mu(1-K\varepsilon)t/\gamma}}{t^{1/2}}$$

where ε is equal to (ψ''_H/ψ''_0), the other symbols having the same significance as in ref. 1. The corresponding expression for a mosaic crystal is:

$$R_y^M = \frac{\pi}{2}\cdot K\,.\,(\mu t\varepsilon/\gamma k)e^{-\mu t/\gamma} = \text{constant} \times e^{-\mu t/\gamma} \times t$$

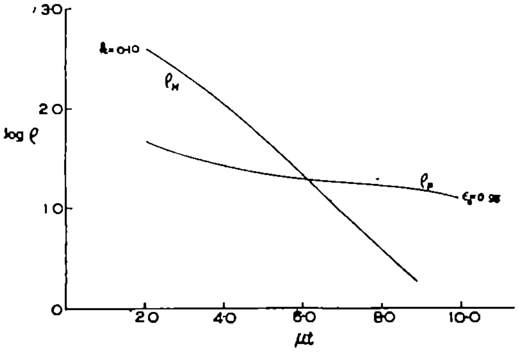

Fig. 1. Variation of the integrated reflexion of a perfect crystal (ρ_P) and of a mosaic crystal (ρ_M) with thickness for a typical X-ray reflexion (expressed in arbitrary units)

Fig. 1 shows the variation with thickness of the integrated reflexions ρ_P and ρ_M which are proportional to R_y^P and R_y^M, respectively, for a typical crystal with $\varepsilon = 0{\cdot}95$, $k = 0{\cdot}10$. In Fig. 1, ρ_P and ρ_M are expressed in arbitrary units, and the exact formulæ for R_y^P and R_y^M have been used to compute these quantities. It will be seen from this that while the mosaic crystal has a higher integrated reflexion than a perfect crystal when the crystal is thin, the situation is reversed when it is thick. The reversal occurs at a thickness of the order of 0·2 mm and greater for typical crystals of reasonable absorption, and the thickness at which the reversal occurs for a particular reflexion can be even smaller than 0·2 mm, if the reflexion is exceptionally strong. It will be seen from the foregoing formulæ that the essential reason for this strange result is the occurrence of the factor $(1 - K\varepsilon)$ in the exponent in the expression for a perfect crystal.

The fact that ρ_P is greater than ρ_M under certain conditions has actually been verified by experiment using calcite crystals of thickness 0·4 mm. The internal reflexion for a perfect crystal has an integrated intensity about six times more than the mosaic crystal. The extension of this observation to the case of the ordinary small crystal bathed in the X-ray beam is not straightforward. Yet, it will be clear that in these cases a reflexion will be partly from the surface and partly through the crystal, and consequently it does not follow that the occurrence of a small degree of perfection in a crystal would necessarily lead to a reduction in intensity.

It has been suggested from a study of polarization effects in perfect and mosaic crystals[2-7] that studies using polarized X-rays can be used to correct for extinction effects. However, a study of the present theory shows that the very basis of the polarization method of correcting for extinction effects requires a re-examination. The results are being worked out and will be reported elsewhere.

Finally, these studies have indicated a very elegant method for studying the variation of the anomalous dispersion part of the scattering factor ψ''_H with the angle of scattering. It is possible to obtain this quantity from the ratio for the different states of polarization from a single perfect crystal.

We thank Sri M. Mallikarjunan for help with the experiments. One of us (R. P.) thanks the Council of Scientific and Industrial Research for the award of a senior fellowship.

CHEMISTRY

Bond Alternation in Heterocyclic Ring Systems

IN a recent communication Davies[1] has made an interesting extension of Longuet-Higgins and Salem's treatment[2] of bond alternation to the case of monocyclic ring compounds of the type $(AB)_n$ such as the phosphonitrilic halides. The total energy is separated into σ- and π-parts: $E = E^\sigma + E^\pi$. He shows that:

$$E^{p\pi} = -\sum_l [\delta^2 + 4(\beta_1^2 + \beta_2^2 + 2\beta_1\beta_2\cos 2\pi l/n)]^{\frac{1}{2}} \quad (1)$$

for 'homomorphic' systems[3], where the combining orbitals on A and B have the same site symmetry, and that:

$$E^{d\pi} = -\sum_l [\delta^2 + 4(\beta_1^2 + \beta_2^2 - 2\beta_1\beta_2\cos 2\pi l/n)]^{\frac{1}{2}} \quad (2)$$

for 'heteromorphic' systems, where the site symmetries are different[4].

Hence $E_{xx}^{p\pi} \equiv (\partial^2 E^{p\pi}/\partial x^2)_{x=0} =$
$$-16\beta_0^2 a^2 \sum_l [\delta^2 + 16\beta_0^2 \cos^2 (l\pi/n)]^{-\frac{1}{2}} \quad (3)$$

and $E_{xx}^{d\pi} \equiv (\partial^2 E^{d\pi}/\partial x^2)_{x=0} =$
$$-16\beta_0^2 a^2 \sum_l [\delta^2 + 16\beta_0^2 \sin^2 (l\pi/n)]^{-\frac{1}{2}} \quad (4)$$

The following symbols have been used in equations (1) to (4): alternate bonds are of length $r_1 = r_0 + x$, $r_2 = r_0 - x$; the resonance integral is[5]:

$$\beta(r) = \beta_0 \exp[-a(r - r_0)]$$

(note that we write a where ref. 2 has $1/a$); δ is the difference between the Coulomb integrals for atoms A and B; and l takes the values

$0, \pm 1, \ldots \pm (m-1), m$, where $m = \frac{1}{2}n$ for n even, and $m = \pm \frac{1}{2}(n-1)$ for n odd. Furthermore[6]:

$$E^{\sigma}_{xx} \equiv (\partial^2 E^{\sigma}/\partial x^2)_{x=0} = 2n(f'')_{x=0} = 2nf''_0, \text{ say} \quad (5)$$

where $f(r)$ is the energy of one σ-bond. Davies stated[1] that E^{π}_{xx} is finite whatever n, and he concluded that: (*a*) for the infinite heterocyclic polyene, the stable configuration always has equal bonds, whatever the value of δ (other than zero); (*b*) for the finite polyene, and for sufficiently small δ, there may be a critical value of n below which bond alternation should occur.

The analysis given here shows that (*a*) is incorrect, and that (*b*) is valid only for certain classes of heterocyclic ring systems.

Let us consider first the infinite ring, whether homomorphic or heteromorphic. It is clear that as $n \rightarrow \infty$ the number of terms in equations (3) or (4), all finite and larger than $16\beta_0^2 a^2(\delta^2 + 16\beta_0^2)^{-\frac{1}{2}}$, also tends to infinity, so that E^{π}_{xx} cannot remain finite. For large n we re-write E^{π}_{xx} as an integral:

$$\begin{aligned} E^{\pi}_{xx} &= -(16\beta_0^2 a^2 n/\pi) \int_{-\frac{1}{2}\pi}^{+\frac{1}{2}\pi} (\delta^2 + 16\beta_0^2 \cos^2 \theta)^{-\frac{1}{2}} d\theta \\ &= (8\beta_0 a^2 n/\pi)\, kK(k) \end{aligned} \quad (6)$$

where $$k = [1 + (\delta/4\beta_0)^2]^{-\frac{1}{2}} \quad (6a)$$

and $K(k)$ is the complete elliptic integral of the first kind. The mathematical analysis is similar to that of the polyacenes[8]. Clearly E^{π}_{xx} is proportional to n, and the same is true for E^{σ}_{xx}. We conclude that whether or not bond alternation occurs in the infinite heterocyclic ring cannot be settled by algebraic reasoning alone. Bond alternation will exist if:

$$E_{xx} \equiv E^{\sigma}_{xx} + E^{\pi}_{xx} = n[2f''_0 + (8\beta_0 a^2/\pi)\, kK(k)] < 0 \quad (7)$$

For $\delta = 0$, $K(k)$ is infinite, and the conclusions of ref. 2 follow. As δ increases, the second term in equation (7) becomes less negative, so that there is a critical value of δ, denoted by Δ, for which E_{xx} changes sign, and above which the infinite ring has equal *A–B* bonds. For all $\delta < \Delta$ the infinite heterocyclic polyene will show bond alternation.

Let us consider next the case of finite n. It is necessary to distinguish two cases.

(1) *Homomorphic systems with n odd* $(=2n'+1)$. These correspond, in the limit $\delta = 0$, to the cyclic 'Hückel' hydrocarbons $C_{4n'+2}H_{4n'+2}$ with a closed shell of π-electrons. When $\delta = 0$,

$$(1/n)|E^{p\pi}_{xx}| = (4|\beta_0|a^2/n) \sum_l \sec\, l\pi/n$$

which is a monotonically increasing function of n. Hence, Longuet-Higgins and Salem found that for fixed a and β_0 there is a critical value of n, which we denote by N_0, above which bond alternation should occur. In the present case $(1/n)|E^{p\pi}_{xx}|$ as given by equation (3) is by inspection also a monotonically increasing function of n. Thus the same conclusions hold good. For all $\delta < \Delta$ there is a critical value of n, denoted by N, above which bond alternation should occur. As δ increases from 0, so will the value of N from N_0. For $\delta > \Delta$ bond alternation never occurs whatever the value of n. As δ increases, less mixing of the π-orbitals of A and B occurs; and for sufficiently large δ, the σ-electrons dictate a symmetrical structure for all values of n.

(2) *Homomorphic systems with even n, and heteromorphic systems.* In our one-electron Hückel approximation, all these systems possess, in the limit $\delta = 0$, a pair of degenerate non-bonding orbitals[3] (for the symmetrical configuration with $r_1 = r_2$) which are to be occupied by two electrons; it is known[9,10] for hydrocarbons that the configuration with bond alternation (and the degeneracy thus removed) is more stable for all values of n. If we now include electron repulsion, this will result in considerable mixing with low-lying states[10,11]. We may describe all this as a 'pseudo' Jahn–Teller effect. For small non-zero δ, the situation will clearly be similar. In both cases, no quantitative significance should be attached to the results of applying Huckel theory; but the interesting conclusions from (4) are worth recording. For small δ, we do find bond alternation predicted for all n; for intermediate δ, there is a critical value of n, *below* which bond alternation occurs; and for larger δ, there is no bond alternation, as in case (1). We can explain this by saying that the separation between the near-degenerate orbitals is independent of n, but the total binding energy increases with n; thus the ratio, and hence the 'pseudo' Jahn–Teller effect, will decrease as n increases.

Examination of the equations shows a close parallelism between the energy $|E^{\pi}|$ and the quantity E_{xx}; so much so, in fact, that we may take over Craig's figure (Fig. 5 in ref. 3*a*, Fig. 4 in ref. 3*b*) as a schematic representation of the Hückel results. The ordinate is now to be read as $(1/n)E_{xx}$; the thick line represents homomorphic, the dashed line heteromorphic systems. When $\delta < \Delta$, $\lim_{n \rightarrow \infty} (1/n)E_{xx}$ is negative; when $\delta > \Delta$ it is positive. For larger δ, $(1/n)E_{xx} > 0$ for all points in the figure. Of course, $(1/n)E_{xx} < 0$ implies bond alternation.

Experimentally, the lowest cyclic phosphazenes do not exhibit bond alternation[12].

It is of interest to estimate the values of the critical parameters Δ and $N(\delta)$. Assuming a bond-order versus bond-length relationship[2] $P(r)$ we find

$$f''_0 = -2\beta_0 a^2 (P_0 - P'_0/a) \quad (8)$$

where P_0 is the bond-order in the symmetrical configuration, given for the infinite polyene by:

$$P_0 = (1/2n)(\partial E^{\pi}/\partial \beta_1)_{r_1 = r_2 = r_0} = (2/\pi)k[K(k) - D(k)] \quad (9)$$

which is very nearly $2/\pi$. Here $D(k) = k^{-2}[K(k) - E(k)]$, where $E(k)$ is the complete elliptic integral of the second kind. P'_0 is the gradient at $r = r_0$ of the curve $P(r)$. From equations (7), (8) and (9) Δ is given after simplification by the solution of:

$$kD(k) = -\pi P'_0/2a \quad (10)$$

where $$k = [1 + (\Delta/4\beta_0)^2]^{-\frac{1}{2}}$$

Davies considered the particular case of the heterocyclic phosphazenes. The spectroscopic assignments[13] for $(PNX_2)_3$ are not sufficiently unambiguous to warrant a separate calculation of P'_0/a but the discussion in ref. 13 suggests that it should be at least comparable with the value for hydrocarbons. As a preliminary estimate we choose $P'_0/a = -2{\cdot}07$ derived from the two benzene force-constants[2,14]. It follows from equation (10) that $\Delta = 0{\cdot}23|\beta_0|$

To determine $N(\delta)$ for case (1) when $\delta < \Delta$, we find from equations (1), (3), (5), (6*a*) and (8) that N is the lowest value of n for which:

$$(k/n) \sum_l \sin^2 l\pi/n \,.\, (1 - k^2 \sin^2 l\pi/n)^{-\frac{1}{2}} > -P'_0/a$$

Of course $N > N_0$, and $N_0 = 17$ (ref. 14) from our chosen value of P_0'/a (but see ref. 15). N_0 and N are, however, sensitive to changes in P_0'/a and might be substantially different for borazoles or cyclic azines.

It must be recognized that a more refined treatment of this question would need also to include: mixing in of d_{yz} character (in Craig's notation); the effect of non-planarity; and also the participation of lone-pair electrons ('π'-bonding')[16].

I AM indebted to Mr. Haigh and Dr. Salem for pointing out the mistake in my communication. They correctly state that $E^{\pi}_{xx} \to \infty$ as $n \to \infty$, and that the infinite heterocyclic ring can have, respectively, equal or unequal bond-lengths depending on whether δ is greater or smaller than a critical value.

The other conclusions of my communication are not affected by this mistake, and they are confirmed by Mr. Haigh and Dr. Salem. I confined myself to the cyclic phosphazenes, and treated them as heteromorphic systems. This gave the interesting result that bond alternation might occur below a critical value of n. Mr. Haigh and Dr. Salem consider other possibilities implicit in my equation (9), and show that, for suitable values of δ, odd homomorphic heterocyclic rings can behave like homocyclic rings, with bond alternation occurring above a critical value of n. In particular, they show that treating the known cyclic phosphazenes as odd homomorphic systems does not affect my result that bond alternation should not occur.

Role of Hydroperoxyl in Hydrogen–Oxygen Flames

THE hydroperoxyl radical has been postulated as an intermediate in numerous oxidation reaction mechanisms. In particular, mechanisms involving it are capable of giving detailed explanations of the explosion limits and reaction-rates in hydrogen–oxygen systems in static reaction vessels[1,2]. In discussing hydrogen–oxygen and hydrogen–air flames, however, reactions of HO_2 are usually omitted, on the assumption that most of the flame reaction occurs at too high a temperature for the HO_2 forming reaction (2) to compete with the chain-branching reaction (1).

$$H + O_2 = OH + O \qquad (1)$$

$$H + O_2 + M = HO_2 + M \qquad (2)$$

We have recently obtained evidence, arising from a detailed investigation of a slow-burning hydrogen–oxygen–nitrogen flame and from calculations involving two faster (higher temperature) flames, that this assumption may be invalid in many cases.

The atmospheric pressure flame selected for detailed examination had a final temperature of 1,072° K and a burning velocity of 9·2 cm sec^{-1} (gas flows measured at 18° C and 760 mm). The initial gas temperature was 336° K. Analysis of the measured temperature profile gave a maximum heat release-rate of 20 (± 2) cal cm^{-3} sec^{-1} at 900° K, while the maximum hydrogen atom concentration, measured by studying the rate of the $H + D_2$ exchange reaction in the flame, was about $2{\cdot}5 \times 10^{-8}$ mole cm^{-3} at this temperature. Further, at 900° K $(O_2) \sim 1$, $(H_2) \sim 11{\cdot}3$ and $(H_2O) \sim 7{\cdot}2$ mole per cent.

Now the second limits of hydrogen–oxygen mixtures in potassium chloride coated reaction vessels at temperatures up to about 850° K are normally assumed to be ultimately controlled by a competition between reactions (1) and (2). At the limit the partial pressures of the reactants and inert gases obey the relationship $2k_1/k_{2\mathrm{H}_2} = (\mathrm{H}_2) + k_{\mathrm{O}_2}(\mathrm{O}_2) + k_M(M)$, where k_M denotes the efficiency of molecule M (relative to hydrogen) as the third body in reaction (2). Clearly, the ratio $2k_1/k_{2\mathrm{H}_2}$ may be found from a study of the variation of the second limit with mixture composition. A short extrapolation of the Arrhenius plot for this ratio from second limit data leads to $k_1/k_{2\mathrm{H}_2} = 150$ mm at 900° K. Second limit data[3–5] also show that $k_{2\mathrm{N}_2} = 0{\cdot}45 k_{2\mathrm{H}_2}$ and $k_{2\mathrm{H}_2\mathrm{O}} \sim 6{\cdot}5 k_{2\mathrm{H}_2}$. For the flame composition at atmospheric pressure it might therefore be expected that reaction (2) is some four to four and a half times as fast as reaction (1), that is, that HO_2 reactions are important at the position of maximum reaction-rate. This conclusion is supported by a simple calculation of the heat release-rate in the flame using the experimental concentration values. In the absence of HO_2 forming reactions, and using $k_1 = 2{\cdot}1 \times 10^{10}$ cm^3 mole^{-1} sec^{-1}, at 900° K (a value which is consistent with the recent literature[5]), together with recent experimental values[6] for the hydrogen atom recombination rate constant, a maximum heat release-rate of about 3 cal cm^{-3} sec^{-1} is obtained (cf. experimental 20 cal cm^{-3} sec^{-1}). Similarly, the measured rate of oxygen consumption in the flame is some four to five times larger than would be predicted from the foregoing value of k_1. It seems highly likely, therefore, that much of the reaction path in this flame is by way of HO_2.

By making the assumption that the HO_2 concentration assumes a kinetic steady state value, it is possible to make an estimate of the HO_2 concentration in the part of the flame near the maximum reaction-rate and also to suggest its main reaction path. Work[1,2] on the hydrogen–oxygen slow reaction and explosion limits suggests that reactions (3)–(6) may have to be considered as steps consuming HO_2.

$$HO_2 + H_2 = H_2O_2 + H \qquad (3)$$

$$HO_2 + H_2O = H_2O_2 + OH \qquad (4)$$

$$H + HO_2 = OH + OH \qquad (5)$$

$$HO_2 + HO_2 = H_2O_2 + O_2 \qquad (6)$$

The ratios of rate constants $k_3^2/k_6 = 0{\cdot}96$ cm^3 mole^{-1} sec^{-1} and $k_5^2/k_6k_2^2 = 1{\cdot}2 \times 10^{-4}$ mole cm^{-3} sec at 500° C have been derived by Baldwin and Mayor[1] on the basis of reaction mechanisms which satisfactorily interpret in detail the features of the hydrogen–oxygen reaction in aged boric acid coated vessels at that temperature. Taking $k_2 = 4{\cdot}7 \times 10^9$ at 500° C, $k_5^2/k_6 = 2{\cdot}6 \times 10^{15}$ cm^3 mole^{-1} sec^{-1}, a value only slightly less than the ratio $Z_5^2/Z_6 = 4{\cdot}8 \times 10^{15}$ quoted by Baldwin and Mayor. Foner and Hudson[7] have recently obtained $k_6 = 1{\cdot}8 \times 10^{12}$ cm^3 mole^{-1} sec^{-1} at room temperature, using mass spectrometry to measure HO_2 concentrations. Further, the very reasonable inclusion of reactions (5) and (6) in the mechanism proposed by Burgess and Robb[8] for the mercury photosensitized reaction of hydrogen and oxygen at room temperature would require the activation energy E_6 to be low, regardless of the actual value of k_6. Taking $E_6 = 0$, the values $k_3 = 1{\cdot}3 \times 10^6$ and $k_5 = 6{\cdot}9 \times 10^{13}$ cm^3 mole^{-1} sec^{-1} at 500° C their result.

An alternative value for k_6 ($= 6{\cdot}5 \times 10^{13}$ cm^3 mole^{-1} sec^{-1} at about 30° C, and implying a collision efficiency close to unity for both reactions (5) and (6)) has been derived by Burgess and Robb[8] in the work already quoted. For reaction (6) such a high collision efficiency seems to us to be somewhat surprising. Taking $E_6 = 0$, it would lead to $k_3 = 7{\cdot}9 \times 10^6$ and $k_5 = 4{\cdot}1 \times 10^{14}$ at 500° C. It should be noted also that both values of k_3 are more than 50 times greater than a third value[9-11] of $1{\cdot}2 \times 10^{11} \exp(-24{,}000/RT)$, giving $k_3 = 2{\cdot}2 \times 10^4$ at 500° C, due to Voevodsky and Tal'Rose[10], and derived from slow reaction and third limit studies of the hydrogen–oxygen system in vessels coated with potassium chloride. In view of the more recent developments in connexion with the hydrogen–oxygen system, values derived from older third limit mechanisms may be open to question.

In the flame at 900° K, $(H)/(H_2) \approx 10^{-3}$ and, for $E_3 - E_5 \approx 25$ kcal mole^{-1}, $k_5(H)/k_3(H_2)$ has a minimum value of the order of 10^4. Reaction (3) is therefore unimportant in this region of the flame. Reaction (4), which is endothermic to the extent of about 29 kcal mole^{-1}, is also unlikely appreciably to affect the kinetics. The main reaction path for the HO_2 is therefore most likely to be via reactions (5) and (6), which together with the HO_2 forming reaction (2) would lead to a kinetic steady state concentration $(HO_2) \sim 8 \times 10^{-10}$ mole cm^{-3} (or about one-thirtieth of the hydrogen atom concentration), if Foner and Hudson's value for k_5 is used, or $(HO_2) \sim 1{\cdot}3 \times 10^{-10}$ mole cm^{-3} using Burgess and Robb's value. Further, the rates of reactions (5) and (6) at 900° K in the flame may now be compared approximately. The ratio, using either value of k_6, is:

$$\frac{R_5}{R_6} = \frac{k_5(H)}{k_6(HO_2)} \approx 1{,}200$$

It therefore seems that reaction (5) provides the main reaction path, and that HO_2 concentration in the flame is considerably smaller than the hydrogen atom concentration. The figures quoted depend, of course, on the kinetic steady state assumption, which is not strictly true in the flame due to the diffusion and gas flow processes. A more accurate numerical calculation will be published in due course.

Determination of the Adsorption of Ethylene on Platinum Electrodes using a Radiotracer Method

THERE has been a recent surge of interest in the mechanism of the electrochemical oxidation of hydrocarbons. Important to any determination of mechanism is a knowledge of the fractional surface coverage of reaction species. This communication deals with the adsorption of ethylene labelled with carbon-14 at the platinum-electrolyte interface as a function of potential and time.

The method for measuring the electrode surface concentration of carbon-14 containing species under electrochemically controlled conditions consists basically in an adaptation of the Joliot method[1,2]. In this work the electrode under study is a thin metal foil (10^4 Å thick), which is placed over the window of a proportional counter (suitable for detecting weak β-rays). The electrode is brought into contact with the solution, and from the count rate, after suitable calibration, it is possible to determine the surface concentration of carbon-14 and from that the surface

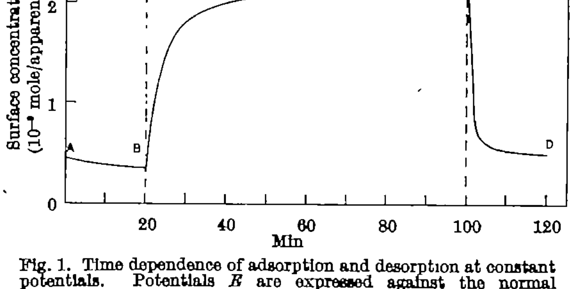

Fig. 1. Time dependence of adsorption and desorption at constant potentials. Potentials E are expressed against the normal hydrogen electrode

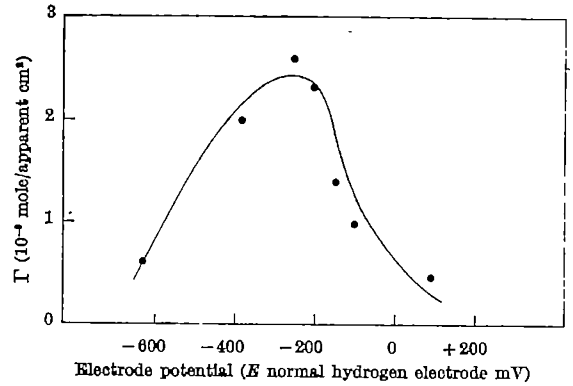

Fig. 2. Dependence of adsorption on potential

concentration of carbon-containing species. Details of the method will be published elsewhere[3].

The electrolysis cell consisted of the usual three-electrode arrangement: a working electrode (metal foil) with reference electrode separated from an auxiliary electrode. The electrode potential of the working electrode was controlled using an electronic potentiostat.

Our results refer to the electrode platinum/1 M sodium hydroxide, ethylene (diss.). The platinum electrode was prepared by electrodepositing a thin layer of platinum black on a gold foil. The electrode was brought into contact with sodium hydroxide solution with an inert (nitrogen) atmosphere above the electrolyte. The working electrode was cleaned by alternate anodic-cathodic pulsing (going from oxygen evolution to hydrogen evolution) and terminating always on a cathodic pulse. The evolved oxygen and hydrogen were removed from solution by sweeping with nitrogen. The electrode was then brought to a potential of +250 mV (normal hydrogen scale). At this stage an aqueous solution of ^{14}C-labelled ethylene was added to the electrolyte of the working electrode compartment so that the concentration of dissolved ethylene was 4×10^{-5} mole/l. The ethylene solution had been prepared in a separate vacuum line. Carbon-14 adsorption measurements, as a function of potential and time, were then started. The solution was kept stirred throughout and the temperature of the system air-thermostatted to 60° C.

The dependence on time of the adsorption at constant potentials is given in Fig. 1. It can be seen that most of the adsorption occurs within 10 min (*BC*). The rate of desorption is somewhat faster (*CD*). The equilibrium values for different potentials are plotted in Fig. 2.

The dependence on potential of adsorption is in general agreement with the adsorption of methanol on platinum determined by an electrochemical method[4]. The potential ranges of desorption correspond to those potentials where a significant increase in coverage of the electrode with hydrogen and oxygen occurs[5].

The electrochemical oxidation of ethylene under identical experimental conditions only proceeds in that range of potential where there is significant ethylene adsorption. At more anodic potentials, where rapid desorption of ethylene occurs (Fig. 1), the electrochemical oxidation of ethylene does not take place[6].

Determination of the roughness factor of our electrode by a gas adsorption method yield surprisingly low values, typically 14. It is thought that this low value may be ascribed to oxidation of the electrode on exposure to air. However, even if we use this roughness factor we find that the maximum fractional coverage of carbon-14-containing species on our electrodes does not rise above about 0·1.

Mass-Spectrometric Observations of Negative Ions in Flame Gases

In view of recent interest in negative ions, it seems useful to report certain results obtained here in the early stages of a programme concerned with negative ions in flames. We have described elsewhere[1] a mass-spectrometric system suitable for the abstraction of ions from hot flame gases, and their subsequent analysis. This has so far largely been used for positive ions[2,3], but it is adaptable to the study of negative ions, albeit with a somewhat reduced sensitivity. A small flame plays directly on a very small sampling hole in a platinum diaphragm, on the other side of which a low pressure is maintained by pumping. It has been shown that the positive ions produced in flames may in some cases undergo reaction to produce other ions in the course of traversing the cooler boundary layer near the walls of the sampling hole[3,4]. In the work described here, no attempt has been made to ascertain whether the negative ions were produced in the flame or in the boundary layer, the primary interest lying rather in the wide variety of ions found.

Flames of premixed hydrogen, oxygen and nitrogen, without additives, showed no detectable negative ions. This implies a concentration of less than 10^7 ions cm^{-3} in the flame gases. Even when alkali metal salts were introduced in small quantities, so as to give electron concentrations of at least 10^{10} electrons cm^{-3} in or near the reaction zone, no negative ions were found there. The species which might have been expected would be OH^- (mass 17) and possibly O^- (mass 16), the corresponding neutral species being the only ones with reasonably high electron affinities known to be present. The absence of OH^- suggests strongly that the electron affinity of the hydroxyl radical is much closer to Branscomb's value[5] of 40 kcal/mole than to that of 65 kcal/mole given by Page[6].

Extension of the observations to the region of the visible tip of the burnt gases, about 3·5 cm downstream from the reaction zone, however, showed a large variety of negative ions in readily measurable amounts. This suggests attachment of the electrons in the cooler regions of the burnt gases, and is in broad agreement with the results of Kinbara and Ikegami[7] on the mobility of negative charge carriers at different

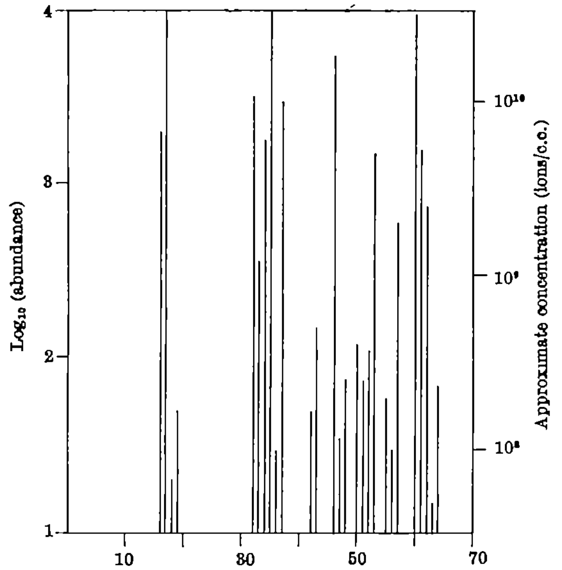

Fig. 1. Relative abundance of negative ions in the burnt gases of a pre-mixed hydrogen–oxygen–nitrogen flame ($H_2/O_2/N_2$ = 3·3/1·0/4·0) at atmospheric pressure with approximately 1 part in 10^6 of added sodium chloride. Measurements relate to a position 3·5 cm downstream from the reaction zone, near the inside tip of the gases

points in the flame. The negative ion count-rates observed at 3·5 cm from the reaction zone are shown in Fig. 1.

Approximate concentrations in the flame gases, to be taken from the right-hand ordinate axis, were obtained by calibration with positive potassium ions at the same sensitivity of detection.

Attention may first be directed to the major peaks. Mass 17 is undoubtedly OH^-, an assignment strengthened by the sizes of the isotopic satellites at masses 18 and 19. Masses 35 and 37 are largely Cl^-, from chlorine derived from the sodium chloride spray, although 35 may be partially a monohydrate of OH^-. Masses 46 and 60 are difficult to assign otherwise than to NO_2^- and CO_3^- respectively, the carbon arising from either flame or atmospheric impurities.

Masses 16 and 32 suggest O^- and O_2^- respectively, while 34 may be assigned to a monohydrate of O^- (not $H_2O_2^-$). Hydrated positive ions have already been found with this apparatus[1], and have been shown to be formed in the cool boundary layer[3,4]. Hydrated negative ions are expected to be less stable than positive ones, but will be most stable for small parent ions. The relative sizes of the peaks at masses 53 and 55 imply that 53 is rather a dihydrate of OH^- than a monohydrate of the larger Cl^- ion.

The other relatively abundant negative ions are at masses 33, 57, 61 and 62. In assigning possible formulæ to these, there seem to be few alternatives to the respective suggestions of HO_2^- (or HS^-), $C_2O_2H^-$, HCO_3^- and NO_3^-. So far as the remainder are concerned, the group 50–52 could be hydrated forms of the group 32–34, 47 a satellite of 46, 48 O_3^- (or possibly SO^-), 63 a satellite of 61 or 62, and 64 SO_2^-. Masses 42 and 43 are here unassigned, and it is hoped that future work will reveal the nature of these, and confirm and strengthen the other suggestions made.

No attempt is made to give mechanisms of formation, although it is clear that, while certain negative ions may form by direct attachment of electrons to the small amounts of the parent species present (for example, OH, O, NO_2), in some cases (for example, CO_3^-) this cannot be the case.

We thank the Research Laboratory of the General Electric Co. (Schenectady) for financial support of this work.

Surface Tension of Aqueous Solutions of Potassium Hydroxide

MANY inorganic substances behave as volume active agents when they are dissolved in water. One such substance is potassium hydroxide. Surface tension measurements were made on a series of aqueous solutions of potassium hydroxide ranging in concentration from 6·5 to 41·2 weight per cent potassium hydroxide.

The potassium hydroxide solutions were prepared with A.C.S. reagent grade potassium hydroxide pellets. The water used in making the solutions was distilled twice in Barnstead tin-lined stills and then put through a two-stage fused quartz still. The specific electrical conductivity of this water at 25° C ranged from $1{\cdot}0 \times 10^{-6}$ to $1{\cdot}2 \times 10^{-6}$ Ω^{-1} cm^{-1}. In preparing these solutions no precautions were taken to eliminate the absorption of carbon dioxide from the atmosphere. The density values of each solution were measured at 20° and at 40° C using vacuum-jacketed pycnometers. Density values at 25° C were calculated assuming linear variation of density with temperature between 20° and 40° C.

The surface tensions were determined by the sessile drop method as prescribed by Bashforth and Adams[1]. The sessile drop was supported by a 'Teflon' block in an air atmosphere. The drops were 20–25 mm in diameter. The 'Teflon' block was cut from a large cylinder obtained from the A–1 Plastics Company, Dallas. The surface of the block was carefully prepared on a lathe; the surface profile is illustrated in Fig. 1.

The system was housed in a special cell made of optical glass, with a loose-fitting cover.

Measurements were made quickly to minimize the effect of atmospheric carbon dioxide. The drop dimensions did not seem to be affected by carbon dioxide during the first hour that a drop stood in the

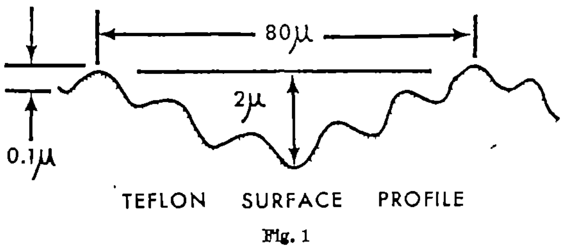

Fig. 1

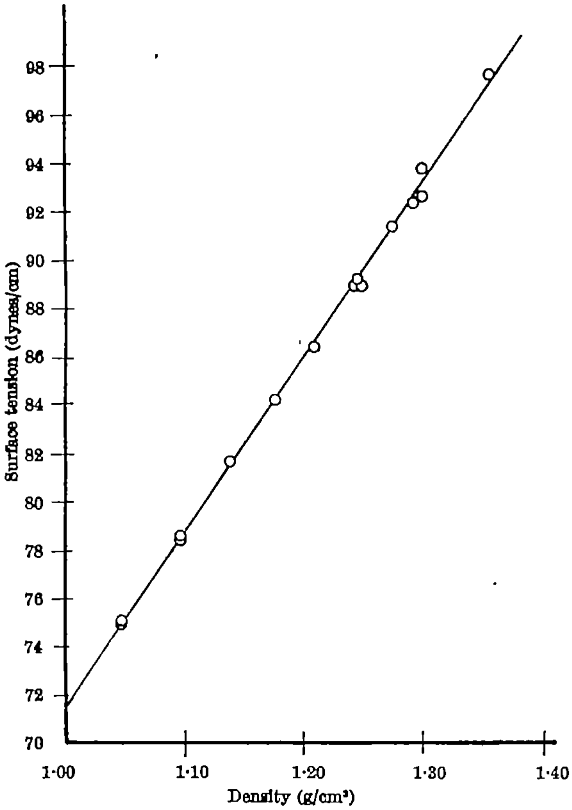

Fig. 2

cell. However, all measurements were completed within 20 min after the drop was formed.

Table 1. SURFACE TENSIONS OF AQUEOUS POTASSIUM HYDROXIDE SOLUTIONS, 25° C

Solution density (g/cm³)	Surface tension (dynes/cm)	Solution density (g/cm³)	Surface tension (dynes/cm)
1·0479	75·1	1·2433	88·9
1·0480	75·1	1·2438	89·2
1·0484	74·9	1·2480	88·9
1·0943	78·5	1·2785	91·4
1·0947	78·5	1·2980	93·4
1·0953	78·7	1·3012	92·6
1·1368	81·7	1·3015	93·8
1·1763	84·2	1·3023	93·9
1·2092	86·4	1·3515	97·6

The surface tension results at 25° are listed in Table 1. Their agreement with a least-squares relationship is shown in Fig. 2. The least-squares line passes through a surface tension of 71·32 at a density of 0·997, while a value of 71·97 dynes/cm is given in the literature[2] for the surface tension of pure water. The surface tension values were collected over a temperature range of 24·7°–25·5° C. During any one measurement the temperature range was never broader than 0·2° C.

BIOCHEMISTRY

Calcium Hydroxide in Sucrose Solution as a Reagent for the Preparation of Water-dispersible Calcium Proteinates

CALCIUM caseinate is extensively applied in nutritional work and in therapeutic practice. Precise details regarding its preparation are not available in the literature. Mechanical drying of mixtures of ammoniacal solution of casein and aqueous calcium hydroxide in our experience offered several practical difficulties. The operations became comparatively easy when a solution of calcium hydroxide in sucrose was used as the reagent. The final drum-dried product so prepared is comparable with pharmaceutical calcium caseinate in all its properties and has met our requirements for nutritional studies. It is a light, white powder, highly acceptable organoleptically, with a good water dispersibility and has a *p*H of 5·8 in solution. The preparation contains 87 per cent protein, and about 6 per cent sucrose. Details of the method (Indian patent application pending) as developed by us with the use of calcium hydroxide in sucrose will be published elsewhere later. We have been regularly producing in this manner small batches of the material for our requirements from easily available and comparatively cheap commercial casein.

Inherent defects in the use as such of aqueous solutions of calcium hydroxide for incorporating calcium into proteins are: (*a*) its low solubility, necessitating the addition of large volumes of the solution for every 1 per cent calcium to be added to the protein; (*b*) the increased heat requirement to remove such large excess of water in the subsequent process of drying; (*c*) the difficulty of adding aqueous calcium hydroxide as a pure solution without its containing some amounts of calcium carbonate. Calcium hydroxide in sucrose solution, wherein a concentration as high as 5 per cent Ca^{++} can be easily built in, overcomes these disadvantages to a large extent. Besides, calcium hydroxide (in sucrose solution) and protein (dispersion in ammonia) would provide an ideal condition, both the reactants being in a homogeneous phase, for the calcium proteinate formation to proceed smoothly and fast. Experiments have shown that such indeed is the case.

Besides casein, the use of calcium hydroxide in sucrose for the preparation of water-dispersible powders from ammoniacal dispersions of proteins or protein-rich preparations of peanut, fresh-water fish and mutton have been tried. Preliminary observations have revealed some remarkable features. Though the calcium-treated proteins from these sources, unlike calcium caseinate, are not fully water dispersible, even so treatment with calcium endows highly acceptable organoleptic and physical properties to the proteins; for example, protein from fresh-water fish acquires a pleasing birefringence. The calcium-treated and drum-dried product obtained in each case, including fish, has remained remarkably free from odour for months. These improved properties are not shared by the products obtained from the same sources (peanut, mutton and fish), but without the use of calcium. Thus this method of processing meat, fish and vegetable proteins would appear to offer scope for extended practical application especially in the preparation of protein-rich foods from those natural sources which by themselves are not readily acceptable. This would depend on proving whether the destruction of odours by treatment with calcium hydroxide is a general phenomenon.

It cannot be stated definitely whether the concepts with regard to binding of calcium as calcium caseinate in milk would hold good for drum-dried preparation of calcium caseinate. In this product, the calcium-protein bond, whatever its nature, has withstood drastic heat treatment (drum drying at 50 lb./in.^{2}) and has preserved easy water dispersibility. We could not obtain evidence for even a trace of Ca^{++} as seen with calcium precipitants or with ethylenediamine tetraacetic acid (EDTA). Indeed, we could add EDTA to the reaction mixture and this made no difference to the water dispersibility and *p*H of the final drum-dried product. More interesting is the observation that even after Ca^{++} in sucrose solution was all chelated with excess EDTA, addition of this chelate to casein in ammonia gave, after drum-drying, a product having the normal water-dispersibility and *p*H characteristics, suggesting that the protein can combine even with EDTA-bound calcium under such conditions. Further experiments to understand this phenomenon are in progress.

These observations give rise to the suggestion that calcium hydroxide in sucrose can possibly find general application as a calcium reagent for reactions of chemical or industrial importance where residual sucrose in the final preparation would not matter.

Influence of Molecular Weight of Deoxyribonucleic Acid on its Incorporation into Neoplastic Cells

In previous publications some kinetic investigations concerning the optimal physico-chemical conditions of incorporation of heterologous and homologous DNA into Novikoff hepatoma cells and Ehrlich ascites carcinoma cells have been given[1,2]. The first phase of incorporation of DNA process into somatic cells is an adsorption of donor DNA molecules on to the cell surface. This adsorption process is not dependent on time and temperature in the Novikoff hepatoma cells. The amount of radioactive DNA is the same at 0° C and 37° C, but is significantly dependent on the kind and composition of the incubation medium (optimum: Robinson's medium and 1/15 M phosphate buffer, *p*H 6·5, v/v).

Preliminary investigations of interaction between tracer DNA and Novikoff hepatoma cells showed that the amount of donor DNA which we found to be resistant to DNase increased during 3–5 h at 0° C, and after reaching a maximum value, did not change at prolonged exposition time. Recent publications[3,4] showed that donor DNA molecules are able to penetrate into the cell nucleus.

The experiment described by Amos[5] suggested that incorporation of donor DNA into chick embryo cells is strongly influenced by basic proteins. We have found that as a result of basic protein interaction with DNA molecules an insoluble complex was formed and precipitated. The enhancing effect of basic proteins could be ascribed rather to the extra-cellular contamination than to incorporation of donor DNA. This phenomenon leads to the conclusion that perhaps the incorporation of donor DNA depends on its molecular weight. Recently published results have shown that only DNA molecules with high molecular weight are able to demonstrate their transforming activity in the bacterial cells.

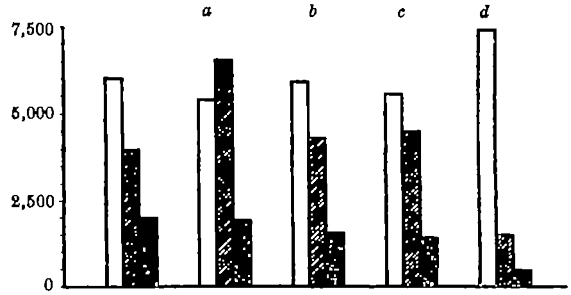

Fig. 1. Incorporation of ^{14}C-DNA into Ehrlich ascites carcinoma cells. DNA-^{14}C (thymidine-^{14}C, biosynthesis *in vitro*). Incubation mixture: 0·8 ml. Ehrlich ascites carcinoma cells, 1 : 1 in Davidson's medium with ascites fluid, 1·5 ml. Davidson's medium, 150 μg DNA-^{14}C, 13,700 c.p.m./150 μg DNA, 120 min at 37° C. The cells were separated from the medium, three times washed with 0·14 M sodium chloride solution, incubated with excess of DNase, five times washed with 0·14 M sodium chloride containing sodium fluoride, and the radioactivity was measured in a Tracerlab flow counter. The DNA was determined at 260 mμ in a Beckman *DU* spectrophotometer. Similar experiments were performed with ^{32}P-DNA samples. Left, control DNA; denatured DNA, *a*, ultra-violet light; *b*, heating; *c*, X-radiation; *d*, homogenization. White, medium; shaded, DNase; black, DNA

The general experimental procedure in our investigations was as follows:

(1) Preparation of radioactive DNA (carbon-14, phosphorus-32), by extraction with 1 M sodium chloride solution and deproteinization with chloroform-*n*-amyl alcohol. Our samples of DNA contained 0·8 per cent protein (Lowry), 1·1 per cent RNA and had a molecular weight of $5·4 - 6·1 \times 10^6$ as measured by viscosity determination. The differentiation of native and denatured DNA was examined as described by Hotchkiss[6]. (2) Exposure of Ehrlich ascites tumour cells in optimal conditions[1] to donor DNA. (3) Separation of the cells from the medium. (4) Determination of the radioactivity in both medium and various cell fractions, for example, free nucleotide fraction, phospholipid fraction, phosphoprotein fraction, free phosphate fraction and in DNA and RNA fractions by various methods. Immediately before exposure of recipient cells to donor DNA, the samples of DNA were degraded and denatured by: (*a*) exposure to 2,000-r. X-radiation; (*b*) exposure to ultra-violet light, λ_{max} 256 mμ, distance 15 cm, for 15 min; (*c*) heating at 100° C for 20 min, followed by rapid cooling; (*d*) homogenization in a glass Potter–Elvehjem homogenizer at 0° C for 5 min at 1,000 r.p.m.

The viscosity decreased significantly only after homogenization. In some experiments the exposed recipient cells were treated with excess of DNase in optimal conditions. The detailed description of materials and experimental methods were published previously[1,4]. It was clearly demonstrated by our experiments that after exposition at 0° C a small amount of donor DNA changes into a form resistant to DNase treatment. Perhaps this form represents the amount of donor DNA which is incorporated and adapted in the cells.

Fig. 1 shows the effect of adsorption and incorporation of various degraded donor DNA samples. Lerman and Tolmach[7] point out that only highly polymerized DNA molecules possess a transforming activity. Fig. 1 also shows that DNA molecules after depolymerization procedure lose their adsorption and incorporation ability. The recipient cells fixed only a very small part of donor DNA added. It is possible that the transforming activity of small DNA molecules is not demonstrated because the incorporation of small DNA molecules is highly decreased. The mechanism of the transforming process is not sufficiently proved as yet. It is not known what amounts of nucleotides are present in a DNA molecule to enable it to demonstrate its transforming activity after incorporation into the genetic apparatus of recipient cells. Neither is it certain whether an oligonucleotide can be incorporated into the terminal position of DNA molecules, which are localized in the genetic apparatus of recipient cells. If it is so, the problem remains whether the process is a mutation or one dependent on transformation.

Isolation from Cottonseed Oil of a Halphen-negative Fraction which causes Pink-'White' Discoloration in Stored Eggs

Sterculic acid, isolated from *Sterculia fœtida* seed oil by Nunn[1] and from cottonseed oil by Shenstone and Vickery[2], and malvalic acid, isolated from cottonseed oil by Shenstone and Vickery[3,4], contain the *cyclo*-propene ring[5], give positive Halphen colour reactions[4,6], and cause pink-'white' discoloration in stored eggs from hens fed these compounds[2,7]. That cottonseed oil may contain a substance, other than malvalic and sterculic acids, which causes pink-'white' discoloration in stored eggs was indicated by our observation that crude cottonseed oil that had been heated at 150° for 4 h or at 200° for 1 h and no longer gave a positive Halphen colour reaction still produced discoloration[8].

We saponified crude cottonseed oil by mixing it with alcoholic potassium hydroxide and allowing the reaction to proceed overnight at room temperature. The fatty acids obtained after acidification were dissolved in acetone, and a fraction soluble at – 60° was obtained. Further fractionations were made by formation of urea inclusion compounds and by crystallization at – 60° from petroleum ether (b.p. 30°–60°) and from acetone. A fraction consisting of 45 g of fatty acids obtained from 4,000 g of crude cottonseed oil gave a strong Halphen reaction. Eggs produced by hens fed this fraction in the ration to supply 89 mg/hen/day developed very pink 'whites' after storage.

Urea inclusion compounds were prepared from 45 g of the active fatty acids and 45 g of urea. A fatty acid fraction (25 g) isolated from the insoluble urea inclusion compounds gave a strong Halphen colour reaction. When this fraction (as urea inclusion compounds) was mixed in the ration to give 50 mg of fatty acids/hen/day varying degrees of pink-'white' discoloration of stored eggs occurred in two experiments, but none occurred in a third. Gas-liquid chromatographic separation of the fatty acid methyl esters indicated that this fraction contained 2·8 per cent methyl sterculate and 56·6 per cent of fatty acid methyl esters with gas-liquid chromatographic retention times similar to methyl linoleate (Table 1). Malvalic acid methyl ester has a retention time similar to methyl linoleate. This fatty acid fraction probably contained 8·2 per cent or more malvalic acid, depending on whether sterculic and malvalic acids were in the same proportion as in cottonseed oil[9] or whether sterculic acid was selectively precipitated in certain steps of the isolation procedure. The variable degrees of pink-'white' egg discoloration obtained were probably caused by losses of the *cyclo*-propenoid fatty acids during the 6 weeks the fractions were mixed with the rations, even though urea inclusion compounds are more stable than the free acids[10].

Table 1. Fatty Acid Composition of Cottonseed Oil Fractions
(Percentage of total fatty acids)

Fatty acid	Urea-insoluble	Soluble
Myristic	1·0	0
Palmitoleic	18·6	5·8
Oleic	19·1	2·8
'Linoleic'	56·5	90·5
Sterculic	2·8	0
Halphen reaction	+	–
Egg 'white' discoloration	slightly pink	very pink

Fatty acids not precipitated by an equal weight of urea (25 g) gave a negative Halphen colour reaction but still produced pink-'white' discoloration consistently when included in the hens' diet at a level to supply 40 mg/hen/day. More than 90 per cent of the methyl esters of these fatty acids had gas-liquid chromatographic retention times similar to methyl linoleate (Table 1). The small amount of fatty acid fraction required to produce pink-'white' discoloration (40 mg/hen/day compared with 25 mg of *cyclo*-propenoid fatty acids given by Shenstone and Vickery[2]) indicates that the active material is present in quite high concentration and must be a constituent of the 'linoleic' peak. The active material in the soluble fraction did not contain a *cyclo*-propenoid ring (negative Halphen reaction), formed a urea inclusion compound less readily than the *cyclo*-propenoid fatty acids, was readily soluble in acetone or in petroleum ether (b.p. 30–60°) at – 60°, had an equivalent chain-length similar to linoleic acid, and was more heat-stable than the *cyclo*-propenoid fatty acids but was still labile on prolonged heating at high temperatures.

Although we believe that crude cottonseed oil contains a fatty acid, other than malvalic and sterculic acids, which causes pink-'white' discoloration of stored eggs, the possibility has not been ruled out that this fatty acid was formed from malvalic or sterculic acid in the isolation procedure.

This work was supported in part by a grant from the National Cottonseed Products Association. We thank Dr. Phillip D. Aines, of Buckeye Cotton Oil Division for the crude cotton-seed oil used in this work.

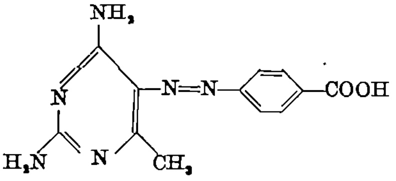
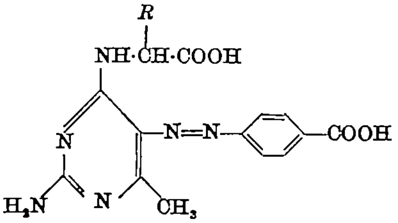
N-(5-Arylazo-4-Pyrimidyl)-Amino-Acids as Growth Inhibitors of *Streptococcus faecalis*

It was shown by Tanaka *et al.*[1,2] that 5-arylazo pyrimidines having different groups (for example, hydroxyl, methyl or amino) at the 2, 4 and 6 positions are strong folic acid antagonists and that some of these possess marked anti-neoplastic properties. They also found that the nature of substituents in the benzene ring of the phenylazo radical was the determining factor for this activity.

We considered it to be of interest to investigate the biological properties of pyrimidine systems containing a 5-arylazo as well as an amino-acid moiety. It is expected that in the proposed compounds the amino-acid side-chain would increase penetration and help maintain a higher blood-level and thus render the molecule as a whole more effective. In continuation of our synthesis of *N*-pyrimidyl amino-acids[3,4], we have, therefore, synthesized several *N*-(2-amino-5-*p*-carboxybenzeneazo-6-methyl-4-pyrimidyl)-amino-acids (compounds II–VII) and have examined their action on *S. faecalis*. The parent compound (I) was also synthesized for comparison. (So far as we know, these compounds (I–VII) are being reported for the first time.)



(I)



(II–VII) (Table 1)

We chose the *p*-carboxybenzeneazo moiety because pyrimidines having this group in the 5-position show marked anti-tumour activity although their inhibitory action on certain micro-organisms are somewhat less pronounced than that of some other compounds of this type[1,2].

All the compounds synthesized were found to inhibit the growth of *S. faecalis*. However, the amino-acid moiety was found to decrease the inhibitory effect to some extent. Thus compounds (II–VII) are less inhibitory than the parent compound (I). It has also been found that among the compounds II–VII the inhibitory activity decreases with the increase of the bulk of the amino-acid moiety (Table 1).

Inhibition studies have also been carried out using other concentrations of pteroylglutamic acid (PGA) and leucovorin and it has been observed that all these compounds can be regarded as competitive antagonists of both PGA and leucovorin in regard to the growth of *S. faecalis*. These compounds also inhibit the growth of *S. faecalis* when PGA in medium (†) is replaced by a combination of adenine and thymine, but to a much lesser extent. The inhibition can be reversed by certain metabolites.

Table 1. INHIBITION OF *S. faecalis* BY *N*-(5-ARYLAZO-4-PYRIMIDYL)-AMINO-ACIDS

Compound	Concentration (μg/ml.) required for 50 per cent inhibition of growth* PGA†	Leucovorin‡
I	0·105	2·17
II : $R = -\mathrm{H}$	1·07	50 00
III§ : $R = -\mathrm{CH_3}$	2·25	178·00
IV§ : $R = -\mathrm{CH_2.CH_3}$	2·70	380 00
V§ : $R = -\mathrm{CH(CH_3)_2}$	7·19	¶
VI§ : $R = -\mathrm{CH(CH_3)CH_2CH_3}$	7·80	¶
VII§ : $R = -\mathrm{CH_2.C_6H_5}$	22·80	¶

* Growth measured turbidimetrically after 18 h at 37° C (micro-organism used was *Streptococcus faecalis* A.T.C.C. 8043).

† Folic acid assay medium (ref. 5) excluding the purine and pyrimidine metabolites was used. Medium contained pteroylglutamic acid (PGA) (0 001 μg/ml.).

‡ Medium same as in †. No PGA used. Concentration of leucovorin (0 001 μg/ml.) refers to 50 per cent of the weight of 'leucovorin' used, since synthetic leucovorin is half as active as naturally occurring citrovorum factor due to the presence of an inactive isomer.

§ All these compounds are of DL-variety.

¶ Half-inhibition concentration could not be reached because the compound was not sufficiently soluble in the basal medium to permit the attainment of the required high concentration.

The metabolites used in the reversal experiments were adenine, guanine, xanthine, uracil, thymine, orotic acid, thymidine, cytidine, PGA, leucovorin, serine and methionine. The inhibition caused by the compounds could, however, be reversed only by thymine, thymidine, PGA and leucovorin. Although PGA and leucovorin are both equally effective for the growth of *S. faecalis*, these *N*-pyrimidyl amino-acid derivatives are much more inhibitory in presence of PGA than in presence of leucovorin (Table 1). These facts suggest that the compounds exert their inhibitory activity mainly by interfering with the enzymatic conversion of PGA to citrovorum factor in the metabolic pathway of *S. faecalis* cell.

We thank the Council of Scientific and Industrial Research, Government of India, for financing this investigation.

Glucose-6-Phosphate and 6-Phosphogluconate Dehydrogenase Activities in Erythrocytes of Monkeys infected with *Plasmodium knowlesi*

CERTAIN drugs, when administered to individuals deficient in erythrocyte glucose-6-phosphate (G-6-P) dehydrogenase, can cause hæmolytic crises. Episodes of acute hæmolytic anæmia caused by a variety of infections have been reported in enzyme-deficient individuals[1]. To investigate if the presence of a similar deficiency in monkeys could explain the severe hæmolysis which is a frequent feature of acute *Plasmodium knowlesi* infections in monkeys, quantitative estimations of erythrocyte G-6-P dehydrogenase were carried out. Fifty-eight rhesus monkeys, *Macaca mulatta*, of both sexes, were examined, and no evidence of dehydrogenase deficiency was found. This finding is in agreement with the recent report of Lie-Injo Luan Eng[2].

Blood was obtained from the saphenous veins of monkeys under general anæsthesia and was stored at 4° C in acid–citrate–dextrose solution. The test was normally performed within 3 h. Glucose-6-

* All erythrocyte preparations for assay were suspended in Krebs–Ringer-phosphate solution (*p*H 7·4) following removal of the plasma and leucocytes.

† Figures in parentheses refer to the concentration of parasites achieved expressed as a percentage of the total number of erythrocytes in the preparation used for assay of both enzymes, otherwise this was more than 90 per cent.

phosphate dehydrogenase was assayed by following the rate of reduction of added nicotinamide–adenine dinucleotide phosphate (NADP) spectrophotometrically at 340 mμ in the presence of substrate (Motulsky, private communication, 1959). All experiments were carried out at 25° C. The individual results gave a mean value of 265 units/min/100 ml. erythrocytes (*S.D.* ± 70), which is very similar to the mean level found in 30 British human subjects of both sexes (275 units/min/100 ml. erythrocytes, *S.D.* ± 62).

The dye test of Motulsky and Campbell[3] was also performed on some of the same animals, but it was found that complete decolorization was not obtained in many of the tests. The difficulty in assessing complete dye reduction was overcome by increasing the amount of NADP in the reagent mixture from 0·1 mg to 0·3 mg, after which a range of incubation times necessary for complete decolorization agreed well with those reported by Lie-Injo Luan Eng[2] for *M. mulatta*. It was thought that the incomplete decolorization might have been due to inefficient hydrogen acceptance by the final acceptor, brilliant cresyl blue, since parallel tests with samples of this dye from different sources gave very variable times of decolorization, a finding in accord with the observations of Knight[4]. Recently, we have performed ageing experiments at 37° C on lysates of monkey erythrocytes and have found that the glucose-6-phosphate dehydrogenase is inactivated much more rapidly than that of similar preparations of human blood. The coenzyme NADP has been shown, in our laboratory and elsewhere[5], to protect the enzyme against inactivation by heat and on dilution.

No linear relationship was found between the levels of parasitæmia in monkeys infected with *P. knowlesi* and the time of decolorization in the Motulsky dye test, although there were indications that parasitæmias of 50 per cent or more shortened the necessary time. This was further investigated by quantitative measurements of erythrocyte G-6-P and 6-phosphogluconate (6-PG) dehydrogenases throughout the course of the infection. Increases in both enzymes were found on parasitization. Moreover, the increases were restricted to the parasitized cells, which were separated from the unparasitized cells by differential centrifugation or sedimentation on standing at 4° C. The uninfected cell enzyme contents remained at the pre-infection levels. Results from 10 experiments are shown in Table 1. There was no reticulocytosis during the course of this acute infection to account for the increased enzyme levels found in infected blood by virtue of the higher levels present in young erythrocytes. Extracts of liberated parasites prepared by a variety of methods revealed virtually no enzyme activity.

Such increases in erythrocyte dehydrogenases were normally detectable within 2 h of parasitization of the cell. Opportunities of observing these changes were facilitated by the synchronous nature of the 24-h asexual life-cycle of *P. knowlesi*.

These findings indicate either that activation of inactive forms of the enzymes, as suggested for G-6-PD (ref. 5), occurs as a result of parasitization, or that the parasite is able to produce the enzymes and to secrete them into the cytoplasm of the host erythrocyte. The second possibility is the less likely, since no residual enzyme activity was found in the parasite extracts. Whether activation is initially an erythrocyte response to the presence of a parasite or is brought about by the parasite for its own requirements, the same material benefits will in either case be derived by both parasite and erythrocyte. Hence, any changes which attempt to stabilize erythrocyte integrity and function are likely to help in maintaining a suitable environment for the parasite.

Such changes in erythrocyte dehydrogenases can regenerate increased amounts of NADPH, which, in addition to parasite requirements, may be required for reduction of any oxidized glutathione or methæmoglobin formed in the host erythrocyte. The results may also suggest that *P. knowlesi* utilizes the pentose phosphate pathway not only for regeneration of NADPH but also for production of the pentose sugars which are required for nucleotide synthesis. That the malaria parasite can synthesize large amounts of nucleic acids has been demonstrated in the studies by Ball *et al.*[6] of *P. knowlesi* and by Whitfeld[7] of *P. berghei*. An increased turn-over of NADPH is required for the large amount of lipid synthesis carried out by *P. knowlesi*[8], for enhancing synthesis of proteins[9] (such synthesis has been shown to occur in *P. knowlesi*[8]), and for regeneration of reduced glutathione which contributes to the sulphur requirements of *P. knowlesi*[10]. An increased rate of NADPH regeneration resulting from an increased utilization of the pentose phosphate pathway is also likely to be required for many other essential syntheses in a rapidly growing parasite.

These observations offer further explanations of why the malaria parasite is an obligate intracellular parasite within the erythrocyte. Furthermore, if deficiency of erythrocyte G-6-PD in young African children is shown convincingly to afford some degree of protection against *P. falciparum* malaria, as suggested by Allison and Clyde[11] on the basis of their investigations, our findings would possibly explain this phenomenon. If *P. falciparum* has a vital requirement of the pentose phosphate pathway similar to that which *P. knowlesi* appears to have, the parasite is unlikely to thrive in enzyme-deficient erythrocytes.

Further experiments with erythrocytes from *P. berghei*-infected mice and from *P. vinckei*-infected hamsters have revealed no significant increases in the levels of these enzymes on infection, but the erythrocytes of both animals before infection have much higher enzyme levels than those of uninfected monkeys. There was no evidence of any reticulocytosis in either of these infections.

Isolation of an Anabolic, Uterotrophic Compound from Corn infected with *Gibberella zeae*

A METABOLITE with possible anabolic and marked uterotrophic activity has been isolated from extracts of the fungus *Gibberella zeae* (*Fusarium graminearum*).

Numerous reports of genital involvement in animals fed spoiled grain[1–4] prompted us to investigate the possible relationship of micro-organisms to this syndrome. During 1957 and 1958 we observed seven widely separated swine herds showing vulvar hypertrophy and occasional vaginal eversion in females, preputial enlargement in castrated males and prominent mammary glands in both sexes. In each case the animals were fed moulded corn. Spoiled grain was procured from each farm, treated with sodium hypochlorite and plated on potato–dextrose agar. Predominant micro-organisms isolated from the samples were *Penicillium* spp., *Cladosporium* sp., *Mucor* spp. and *Gibberella zeae*. Cultures of these moulds were grown on sterile ground corn (35 per cent moisture) in flasks stored at about 24° C for 2–3 weeks. This moulded corn was fed *ad libitum* to sexually immature female pigs. Within four days, vulvar and mammary enlargement were elicited only in those animals fed corn seeded with *G. zeae* isolates. Similarly prepared corn fed for six days to five mature, ovariectomized mice produced an average uterine weight of 94·3 mg compared with 22·6 mg for the control animals. An alcoholic extract of the *Gibberella* moulded corn incorporated in sesame oil and injected subcutaneously into 10 castrated female mice at a dose of 0·1 ml. per animal daily for 3 days produced an average uterine weight of 60·7 mg compared with 20·6 mg for the controls. Nine isolates of *G. zeae* were obtained which produced varying degrees of uterotrophic activity.

To obtain material for chemical and pharmacological tests, a study was made of the cultural requisites for the production of the active principle. Suitable substrates include wheat or barley as well as corn or a synthetic medium containing mineral salts and carbohydrates including corn starch, high test molasses or D-glucose. An easily separable, water-soluble fraction, toxic for mice, is occasionally produced concurrently with the metabolite. This confirms the earlier work of Christiansen and Kernkamp[5] and Mitchell and Beadles[6] associating toxicity with the ingestion of *G. zeae*-infected grain.

Recovery of the metabolite is effected by water extraction of the corn–mycelial mixture in a high-speed blender to remove the water-soluble fractions. The wet cake remaining after filtration is repeatedly blender-extracted with anhydrous ethanol to remove the active principle. The alcoholic extracts are combined and the solvent removed by distillation. An aqueous-organic phase partition of the resulting residue is followed by application of the concentrate to a column of synthetic magnesium-silicate. Subsequent development by gradient elution using solvents of increasing polarity separates the active component. The solvent mixture is evaporated from the active fraction resulting in a white, crystalline mass which upon recrystallization has a melting point range of 161°–163° C, $(\alpha)25^\circ/\mathrm{Hg} = -82^\circ$ ($c. = 2{\cdot}4$ ethanol). A methanolic solution of the metabolite exhibits a bright, greenish-blue fluorescence when exposed to ultra-violet light. Ultra-violet absorption peaks occur at about 237, 275 and 315 mμ (methanol). Additional chemical, physical and structural data will be forthcoming as pure material becomes available.

Preliminary experiments indicate that partially purified concentrates of the active principle are effective in improving growth-rate and feed efficiency in sheep.

Bile Pigment in *Eucypris virens* (Jurine)

Eucypris virens (Crustacea : Ostracoda) is a common ostracod with green patches on the valves of its carapace. When treated with yellow nitric acid these green patches become purple, then red, orange and finally yellow. This sequence is typical of the later stages of the Gmelin reaction, indicating the presence of a bile pigment.

Several hundred *E. virens* were soaked overnight in acid methanol (5 per cent hydrochloric acid), to give a clear blue-green solution with an absorption maximum at 655 mμ. The pigment passed readily into chloroform after dilution of the acid methanol with water. In dry chloroform absorption maxima were found at 362 and 660 mμ. The chloroform solution was then evaporated and the pigment taken into methanol. The solution in methanol did not fluoresce in ultra-violet light, nor did it fluoresce on the addition of zinc acetate, but when a trace of iodine was added a brilliant pink fluorescence appeared. This fluorescent solution, stabilized with a trace of ammonia, showed a strong absorption maximum at 625 mμ. This indicates that the pigment was mesobiliverdin, or a pigment very similar to it.

A pigment with similar properties has been obtained by cold acid hydrolysis of C-phycocyanin[1]. This raises the possibility that the original pigment in the ostracod was not a bilatriene of the mesobiliverdin type, but a biladiene similar to those occurring in the blue-green algae on which this ostracod feeds. This possibility was tested by taking fresh *E. virens* which had been passed through several changes of clean water to allow them to empty their intestines, and homogenizing them in 2 per cent hydrochloric acid in methanol. The blue-green solution was cleared by centrifuging, then diluted with water and the pigment taken, not very easily, into chloroform. The chloroform solution was washed with dilute sodium bicarbonate, and a small volume of methanol was added. This solution showed a pink fluorescence in ultraviolet light, and the fluorescence was greatly intensified by the addition of zinc acetate. Addition of iodine increased the fluorescence slightly, but then turned it to a pale green. The pink fluorescence was completely quenched by the addition of mineral acids, thus distinguishing it from the fluorescence of porphyrins, and indicating that the pigment was a biladiene of the a, b type.

It has previously been shown[2] that another ostracod, *Heterocypris incongruens* (Ramdohr), accumulates biladienes, derived from blue-green algae, in the form of small granules in the wall of its gut, but not outside the gut in the valves of the carapace. *Eucypris virens* also accumulates biladienes in the wall of its gut, but in addition transfers some to the valves of its carapace. The mesobiliverdin obtained from the first extract was due to the hydrolysis of the biladiene in the strong acid; when the pigment was extracted in weaker acid and examined immediately to minimize hydrolysis the indications were that in the ostracod the pigment was present as a biladiene.

It is probable that the green colour in the carapace valves of other ostracods is due to bile pigments: the patches on the shell of *Cypridopsis aculeata* (O. G. Costa) give a positive Gmelin reaction.

PHYSIOLOGY

Injection of Alkaline Cations into Cat Spinal Motoneurones

The effects of electrophoretic injection of some cations into cat spinal motoneurones have already been reported[1]. The injection of K^+ displaces only the equilibrium potential of the inhibitory post-synaptic potential because of the increased intracellular chloride concentration which is caused by the inward movement of Cl^- ions during the flow of the potassium-injecting current. On the other hand, the effects of Na^+ injections are characterized by changes in the resting-, spike-, and after-potentials and the inhibitory post-synaptic potential, which can be explained by the intracellular increase of Na^+, the reciprocal decrease of K^+, and the secondary increase of Cl^-. The recovery of these potentials subsequent to a Na^+ injection represents the time-course of the sodium extrusion from the motoneurones. According to a recent analysis, the increased intracellular sodium concentration decreases exponentially with a mean time constant of 91 sec; virtually full recovery being attained after about 6 min[2]. Several other cations have now been injected into cat motoneurones, and this article will describe the effects of injections of Li^+, Cs^+, and Rb^+ ions on the motoneurone potentials and the rates of their removal from the cells.

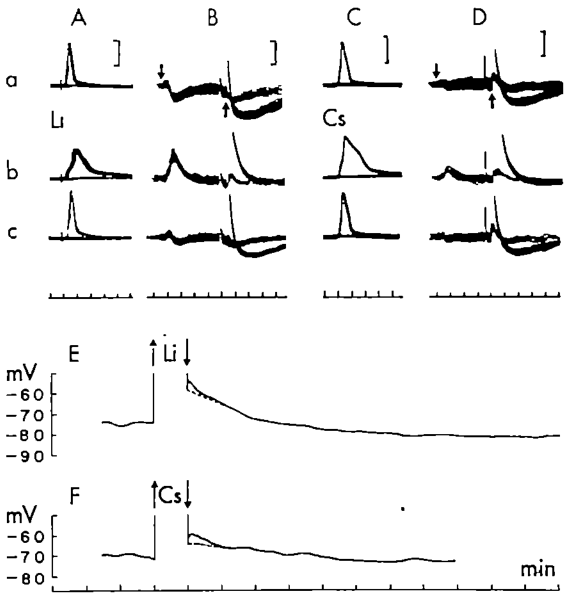

Fig. 1. *A* and *C*, antidromically evoked spike potentials in two different motoneurones which were impaled with Li^+ and Cs^+ containing micro-electrodes respectively. *B* and *D*, illustrating, with higher amplification and slower sweep velocity, the polysynaptic inhibitory post-synaptic potentials (stimulation at downward arrows) and the after-potentials following the spikes in *A* and *C*, respectively. The ventral root stimulus was at threshold intensity for the axon which belonged to the impaled motoneurone, so as to induce an antidromic invasion in about half the trials. Traces without invasion show the inhibitory post-synaptic potential evoked through the Renshaw pathway. Note that in *D* the antidromic invasion was facilitated by the monosynaptically induced excitatory post-synaptic potential. Records in upper row (*a*) of *A–D* were taken before injection, those in *b* of *A* and *B* at 41 sec after the Li^+ injection and of *C* and *D* at 35 sec after the Cs^+ injection. Records in *c* were taken at 660 sec for *A* and *B* and at 355 sec for *C* and *D*, after respective injections. Time-scales, 2 msec for *A* and *C* and 10 msec for *B* and *D*. Voltage calibrations, 50 mV for *A* and *C* and 5 mV for *B* and *D*. *E* and *F*, resting potential before and after injections of Li^+ (*E*) and Cs^+ (*F*) in trials from which records *A–D* were obtained. Solid lines were reproduced from charts of an ink-writing recorder and the interrupted lines superposed thereon indicate the correction for the artefact that was introduced by the passage of the ion-injecting current through the recording micro-electrode (ref. 3)

A laminectomy including all lumbar vertebræ was made in cats anæsthetized with pentobarbitone sodium. The cord was transected at the L_1- or L_2-level. Glass micro-electrodes were filled with solutions containing 2 M lithium sulphate, 1 M cæsium sulphate or 1·6 M rubidium sulphate, and inserted into motoneurones at the L_7- and S_1-levels. Intracellular recording from motoneurones and electrophoretic injections of cations into them were done as described previously[3]. The injections described here were performed by the passage of a current of 5×10^{-8} amp for 60 sec.

Fig. 1, *A*, *B* and *E*, shows changes in a motoneurone following an injection of Li^+ ions. Immediately after the injection, there was a depolarization of the resting potential (*E*) and a decline of the spike with a concomitant decrease of its rising and falling slopes (*A*). The active membrane potential (overshoot or reversal) at the spike peak was reduced, or there was even failure of reversal. There was also a reduction of the after-hyperpolarization and a conversion of the inhibitory post-synaptic potential from the original hyperpolarization to a depolarization (*B*). The pattern of these changes due to a Li^+ injection is the same as that obtained by a Na^+ injection[1]; the decrease of the active membrane potential and of the rising slope of the spike indicates that the enhanced permeability which causes the spike potential fails to discriminate between Li^+ and Na^+, which also occurs with other excitable membranes[4–6]. The effects of a Li^+ injection on the resting potential, after-potential and the falling slope of the spike can be explained by the displacement of intracellular K^+ ions.

The effects of Cs^+ ions are illustrated in Fig. 1, *C*, *D* and *F*. The most striking difference between Li^+ and Cs^+ was the lack of depression of the rising slope and active membrane potential of the spike subsequent to a Cs^+ injection. As was assumed already for choline ions[1], Cs^+ appears to be distinguished from Na^+ and Li^+ by the sodium-carrier system which is activated in the spike initiation[7]. Changes in the falling slope of the spike, the after-potential, and the resting potential were qualitatively identical to those produced by Li^+ or Na^+, thus indicating that Cs^+ ions are not effective substitutes for K^+ ions in the generation of these potentials. In contrast, injection of Rb^+ did not affect the motoneurone potentials except for the inhibitory post-synaptic potential that was reduced or sometimes reversed to a depolarizing potential, just as was observed on injection of K^+. It was not possible to discriminate between the effects of Rb^+ and K^+, either qualitatively or quantitatively.

The depolarizing action on the resting membrane can be related to the permeability of the motoneurone membrane to the injected cations, which determines the degree of depletion of the intracellular K^+ during their injection as well as their ability to replace the intracellular K^+ in generating the resting potential. Since, however, the depolarization produced by Na^+ injections varied according to the level of the resting potential[2], a precise comparison of this effect between different cations requires further statistical treatment. Nevertheless, it may be pointed out that the depolarizing action decreases in the order: $Li^+ > Na^+ > Cs^+$; the membrane depolarization actually obtained was up to 47 mV with Li^+, up to 35 mV with Na^+, and never more than 13 mV with Cs^+. The sequence of the order of permeability of the cat motoneurone membrane thus would be given by the series: $K^+ = Rb^+ > Cs^+ > Na^+ > Li^+$, which is in reasonable agreement with those reported in other tissues[4,8].

Changes induced by Li^+ injections completely recovered within 13 min. The recovery of the action potential and of the inhibitory post-synaptic potential was exponential with a mean time constant of 188 sec. Li^+ ions thus appear to be extruded from motoneurones at a rate about half that for Na^+. Since the inefficacy of the active extrusion of Li^+ ions has been shown in frog muscle[4], human erythrocytes[9], frog skin[10] and, though indirectly, in mammalian C fibres[11], the fast rate of Li^+ extrusion here obtained for cat motoneurones would provide a peculiar and unique feature of the membrane of mammalian nerve cells. The pharmacological action of Li^+ on the human central nervous system may not be attributable to accumulation of Li^+ ions in nerve cells[4,12]. The effects of Cs^+ injections decreased exponentially with a mean time constant of 81 sec, full recovery being attained within 6 min. Cs^+ ions are thus removed from motoneurones at a rate comparable with that for Na^+.

Dissociation of Electrocortical Activation and Behavioural Arousal

THE fact that electrocortical 'activation' and behavioural 'arousal' are often correlated has led to interchangeable use of these terms in recent years. This identity stems from the extensive research of Magoun and Lindsley[1], who have put forward the unifying hypothesis that both wakefulness and low-voltage, fast electro-corticographic (ECG) activity depend on the 'tonic' facilitatory effect of the ascending reticular system on the cerebral cortex. Early work by Ranson[2] and Hess[3] had demonstrated that: (*a*) stimulation of the posterior hypothalamus results in behavioural arousal from sleep; (*b*) bilateral lesions of this region are accompanied by a chronic state of somnolence, or coma. Such effects were later duplicated by: (1) stimulation or (2) extensive destruction of the midbrain reticular formation[1]. In the interest of parsimony it was proposed that the posterior hypothalamus is involved in maintaining the waking state only in so far as it is a part of the ascending reticular system[1]. The present experiments were designed to test the following hypothesis: while the ascending reticular system mediates electrocortical 'tone', the posterior hypothalamic region has a functionally separable role in maintaining the waking state.

Thirty cats were used. Under pentobarbital anæsthesia, bilateral lesions were made in the posterior hypothalamic region by passing radio-frequency currents through stereotaxically placed electrodes. Bipolar stimulating electrodes were permanently implanted in the reticular formation, approximately 3 mm lateral to the midline at the level of the superior

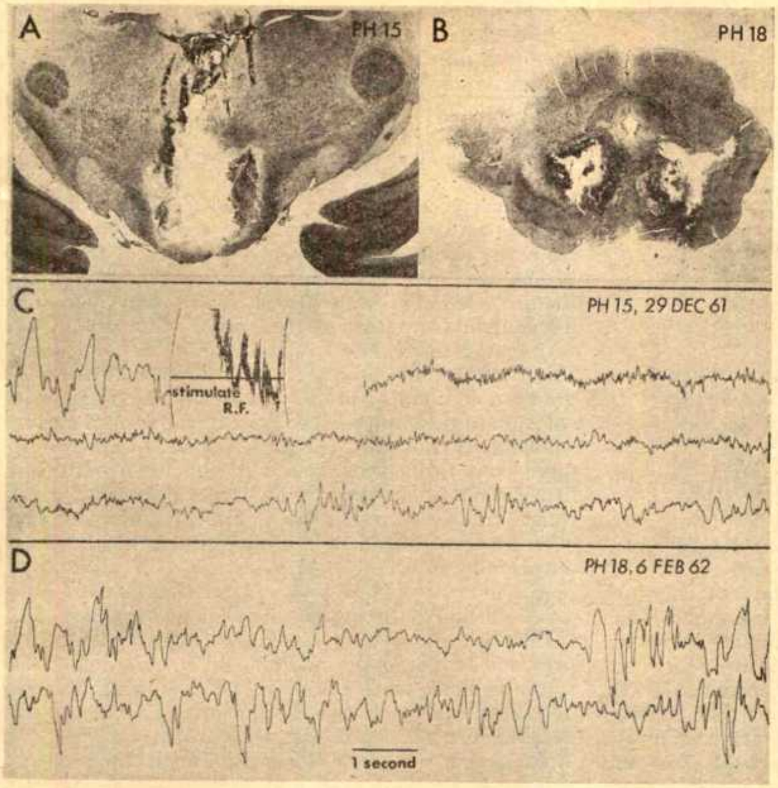

Fig. 1. ECG activity following lesions in posterior hypothalamic region and reticular formation. *A*, 40μ frozen section, stained with cresyl violet, showing hypothalamic lesion in cat *PH*-15; *B*, 40μ frozen section, stained with cresyl violet, showing tegmental lesion in cat *PH*-18; *C*, effect of reticular formation stimulation on activity of left posterior cortex of somnolent cat (*PH*-15) with lesion in posterior hypothalamic region. Line 2 starts 60 sec, line 3, 120 sec, after stimulus termination (cal. = 100 μV); *D*, activity of left posterior cortex during visual tracking, in awake cat (*PH*-18) with tegmental lesion. This ECG pattern was also present before and after the tracking session. The two tracings are continuous. (Cal. not available)

colliculus; recording electrodes were positioned epidurally on anterior and posterior cortex. After recovery from anæsthesia, the state of the surviving cats ranged from uninterrupted somnolence throughout the period of survival, to alert, attentive behaviour, depending on the locus and extent of the lesions. Animals with nearly complete lesions of the posterior hypothalamic region (sparing the ventromedial nuclei anteriorly and caudal portion of the mammillary bodies posteriorly, but including varying amounts of lateral hypothalamus, Fig. 1*a*) were apparently unresponsive to sensory stimuli. They required tube-feeding, showed no spontaneous movement, and could not be behaviourally aroused.

Beginning with the second postoperative day, ECG recordings were taken. One to two-second trains of 0·1 msec pulses were delivered to the midbrain reticular formation at a frequency of 100/sec when the cats appeared to be behaviourally asleep and when the ECG was also characterized by high-voltage, slow activity. It was found that cats with hypothalamic lesions resulting in somnolence showed a clear-cut dissociation between ECG activation and arousal. Although ECG desynchronization resulted from midbrain reticular formation stimulation, the only behavioural response of the somnolent cats was a highly stereotyped head and limb extension during the stimulus strain, followed by passive return to the sleeping posture within a few seconds. When stimulus intensity was at ECG desynchronization threshold, not even the passive return outlasted the stimulus. These movements were never accompanied by orientation to visual or auditory stimuli and clearly could not be interpreted as arousal. The ECG activation, on the other hand, outlasted the stereotyped, stimulus-bound movement by periods ranging from one or two seconds to more than four minutes, depending on the intensity of stimulation (Fig 1*c*). Peripheral stimulation also induced lasting ECG activation despite the absence of signs of behavioural arousal or orientation to the environment. This desynchronization of ECG activity can be distinguished from what has been described by Jouvet[4] as 'paradoxical sleep'. Stimulation of the midbrain reticular formation, which produced ECG activation alone in somnolent cats, produced desynchronization and behavioural arousal in normal or drowsy cats; the desynchronization pattern in the somnolent cats is therefore what has commonly been identified with behavioural arousal.

Since these data show that it is possible to dissociate behavioural arousal and ECG activation, the next problem to be considered was whether it is possible to dissociate behavioural sleep and ECG synchronization[5]. Bitateral lesions were placed in the midbrain reticular formation, sparing most of the peduncles and periventricular grey (Fig. 1*b*). Such lesions were followed not by somnolence but rather by sluggish behaviour. The animals fed themselves, attended to visual and auditory cues, and showed alternation of sleep and wakefulness. The ECG pattern, however, showed spontaneous shifts from slow, high-voltage activity to fast, low-voltage activity which correlated only approximately with behavioural arousal. In the record shown in Fig. 1*d*, for example, the animal followed a visual stimulus during the 24-sec period shown. This pattern persisted for 5 min, and was only momentarily interrupted by low-voltage, fast activity during the course of the experimental session, although the cat was awake and attentive throughout.

These experiments confirm the classical findings of Ranson[2] that lesions of the posterior hypothalamus are accompanied by behavioural somnolence. The critical findings of this study are: (*a*) that behavioural arousal is lost following posterior hypothalamic lesions despite the functional integrity of an ascending pathway from the midbrain reticular formation which can provide ECG desynchronization; (*b*) that slow ECG activity is the dominant pattern following lesions of the midbrain reticular formation, despite the integrity of a conducting pathway which can mediate arousal and alert attentive behaviour. This leads to the conclusion that although behavioural arousal requires the integrity of the posterior hypothalamic region, induced ECG activation is not critically dependent on pathways funnelling through this region.

Independence of Transfer of Solute and Solvent across the Rat Ileum

FROM experiments on the rat ileum *in vitro* Fisher[1] and Smyth and Taylor[2], using glucose-free media and metabolic inhibitors, suggested that the movement of water across the ileum was an active, metabolic dependent process. Parsons and Wingate[3] observed that net movement of water took place against an osmotic gradient, that is, with the mucosal solution hypertonic to the serosal there was a net water movement from the mucosal to the serosal surface. These workers again suggested that the process was an active one relatively independent of osmotic forces. Also, Smyth and Taylor[4] using a glucose-free medium with isolated rat ileum found that the water movement was lowered in the absence of glucose and interpreted the process of water movement as being an active one. Hendley and Smyth[5] have reported experiments showing that the concentration of sodium in the fluid appearing on the serosal surface is higher than the concentration on the mucosal surface of the rat intestine, indicating that there was active sodium transport, but have drawn no conclusions as to its primary role in solvent movement. Curran and Solomon[6] and Curran[7], on the other hand, have shown, both *in vivo* and *in vitro*, that the movement of water across the rat ileum is secondarily dependent on active transport of solute. Removal of the glucose from the medium results in a lowering of the solute transport and hence a fall in water movement. Similarly, using metabolic inhibitors the primary action of these was demonstrated to be on the salt transport mechanism and the water movement was shown to be only a secondary effect. Furthermore, the experiments of Curran[7] show that, with isotonic conditions on both sides of the gut, a gradient of water activity is established as a result of the net solute transfer, and this is sufficient to explain the net solvent movement, thus affirming the passive nature of the water transfer.

The quantitative relation between water movement across the ileum and the sugar concentration in the medium, particularly that of glucose, which has been demonstrated by many authors (Smyth *et al.*[8]; Crane[9] and Wilson[10]) would appear to be a secondary phenomenon, the glucose being primarily required to supply the necessary energy for the active salt transport.

The active salt transport (both sodium and chloride are transported, Curran[7]) across the isolated ileum is from the mucosal to the serosal surface of the membrane, and under isotonic conditions the net movement of water is towards the serosal surface (Table 1). To demonstrate further the passive nature of the water movement, and to illustrate the dependence of this transfer on water activity gradients, an osmotic gradient could be established with the mucosal surface solution hypertonic with respect to the serosal surface solution. The net water movement and sodium fluxes determined in such experiments would confirm either of the two main hypotheses concerning water transfer across the rat ileum. If the water were actively transported then it should be moved against an activity gradient (for definition of 'active transport' see reviews by Rosenberg[11] and Ussing[12]); however, as the results indicate, this is not the case.

Female rats (Wistar strain) were starved for 18 h previous to the experiments, and after ether anaesthesia the intestines were removed following washing in cold 0·9 per cent saline solution. The ileum was divided into five equal length segments (16–17 cm); only the first three portions beginning at the duodenal end were used, however, and everted sacs made from them according to the method of Wilson and Wiseman[13], using the modification of Parsons, Smyth and Taylor[14] for longer pieces of intestine. The sacs were filled with 1 ml. of Krebs–Ringer bicarbonate solution containing 0·5 per cent glucose, and suspended in 10 ml. of this medium. After 3 min gassing with a 95 per cent oxygen–5 per cent carbon dioxide mixture, the flask was sealed and placed in a water bath at 37° C. The sacs were weighed empty and when containing the saline medium, both before and after the incubation period of 1 h. From these results the net water movement and the tissue water uptake were determined. In the same experiments influx and outflux of sodium was determined using sodium-24 (R.C.C., Amersham). The influx and outflux, however, were measured in different experiments. Counting was done, using dried 0·2 ml. samples of the solutions labelled with sodium-24, with an end-window Geiger–Müller tube; the suitable corrections were applied to the counts for decay during the time of the experiment, all counts being corrected to zero time.

Six animals were treated as already described, with identical solutions of the saline medium on either side of the membrane. A further group of six animals differed in having on the mucosal surface the saline

containing 150 mmoles/l. of mannitol, resulting in an osmotic gradient of 150 mmoles from the serosal to the mucosal side of the gut. Mannitol has been shown to penetrate very slowly through the rat gut and thus the osmotic gradient used would not be expected to vary significantly during the course of the experimental period[7,15]. In each group of six animals three animals were utilized (that is, nine pieces of ileum) for determining sodium outflux by placing the sodium-24 on the serosal surface, that is, inside the sac, and three animals (again nine pieces of gut) were used for determining the sodium influx with the sodium-24 on the mucosal surface. In all the experiments the net flux of water was determined by changes in weight of the tissue and of the serosal fluid. There was no statistical difference between the water movement measurements irrespective of whether the sodium-24 was inside the sac or in the outside solution.

The results of this experiment are summarized in Table 1, where each of the three segments per animal are given, segment 1, the most anterior, being taken from the ileum immediately posterior to the duodenum. The results show that with isotonic conditions on each side of the membrane, in each segment there is a net transfer of solvent from mucosal to serosal fluids occurring together with a net transport of sodium (expressed as μequiv./cm length/h).

When the mucosal surface is made hypertonic to the serosal, with no change in the sodium concentration on either side of the membrane, there is still active sodium transport of quantitatively the same order as that obtained under isotonic conditions. The net water transfer, however, is almost negligible, the hypertonicity of the mucosal fluid reducing the net water flux to zero. In addition the tissue fluid is reduced when non-isotonic conditions prevail. These results clearly indicate that the water transfer across the ileum of the rat is dependent on the water activity gradients alone. That the process is not an active one is seen from the fact that the transfer is entirely accounted for by the physical properties of the two phases separated by the membrane.

Although concentration gradients of the magnitude used in these experiments are perhaps not those found in the intact animal, they do offer a method of separating the active and passive processes occurring across the membrane, and demonstrate that water is not absorbed against an osmotic gradient.

Since the net sodium flux remains unaltered with isotonic or hypertonic conditions existing across the ileum this further suggests that the sodium and water move in different channels across this membrane. Evidence has been presented by Ussing and Andersen[16] and Koefoed-Johnsen and Ussing[17] that solvent drag, as a result of osmotic water flow, may alter the ionic flow ratio ($M_{\text{in}}/M_{\text{out}}$) in the case of frog skin. It has also been shown recently by Schoeffeniels and Tercafs[18] that in isolated frog skin the passive movement of sodium (that is, outflux) and the water flux take place through spacially separate structures.

Our results indicate, since outflow of water does not cause any alteration in the sodium outflux, that also in rat ileum this spacial separation of the passive sodium movement and water movement may exist. The sodium influx, which is an active process taking place in the non-short-circuited membrane against an electrochemical gradient (serosa positive with respect to mucosa), remains unaffected by the reduction in net water movement, thus indicating that solvent drag plays only a small part in the salt transport across the rat ileum. Since our results indicate that there is no 'drag' effect on the influx of sodium, as well as none on the outflux, then it may be that the active movement of sodium (that is, influx) and the water movement take place through spacially separate structures. This appears to be unlike the conditions in amphibian skin, where evidence has been presented by Ussing and Andersen[16] that the sodium influx takes place through water-filled pores in the membrane. Curran[7], like ourselves, regards the solvent drag as playing virtually no part in the transport process across the rat ileum.

The results obtained here support the concept of a passive movement of water through the rat ileum, as in many biological membranes, and provide further information for the understanding of cellular permeability problems.

We thank the Nuffield Foundation for providing a research studentship for one of us (K. G.), and the British Council for a bursary (B. S.).

PHARMACOLOGY

Ability of Some Antirheumatic Drugs to uncouple Oxidative Phosphorylation

Adams and Cobb[1] directed attention to the fact that certain non-hormonal antirheumatic (anti-inflammatory) drugs uncouple oxidative phosphorylation in liver mitochondria, citing phenylbutazone and salicylic acid as two examples. This correlation can now be extended to include certain analogues of these two drugs and at least three other types of anti-inflammatory agents not chemically related to either salicylate or phenylbutazone, exemplified by cinchophene, glycyrrhetinic acid and certain derivatives of anthranilic acid.

Cinchophene (2-phenylcinchoninic acid) and its 3-hydroxy derivative were formerly used as analgesic-antirheumatic agents but are now known to cause hepatic injury. Glycyrrhetinic acid (3-hydroxy-11-oxo-olean-12-en-30-oic acid), the aglycone of glycyrrhizin from liquorice, is a relatively powerful anti-inflammatory drug in animals[2-4]. Glycyrrhizin itself also exhibits some anti-inflammatory activity[5]. *N*-(α,α,α-trifluoro-*m*-tolyl)anthranilic acid (*CI*-440, flufenamic acid)[6] and *N*-(2,3,xylyl)anthranilic acid (*CI-473*, mefenamic acid)[7] are comparable with phenylbutazone in anti-inflammatory assays with laboratory animals. We have now found that these drugs also uncouple oxidative phosphorylation and stimulate the adenosine triphosphatase (ATPase) activity of rat liver mitochondria. Furthermore, we have evidence that these particular drugs also uncouple oxidative phosphorylation in at least two connective tissues, that is, tissue upon which antirheumatic drugs must exert some effect *in vivo*. All these drugs and 2 : 4-dinitrophenol, a powerful uncoupler of oxidative phosphorylation, inhibited both the incorporation of orthophosphate into organic phosphates and the ATP-dependent biosynthesis by cartilage and cornea of mucopolysaccharide sulphates (which are characteristic structural components of animal connective tissues).

Oxidative phosphorylation with succinate as substrate at 30° and mitochondrial ATPase activity at 20° were measured by described procedures[8,9]. Drugs were added either as solutions in 25 µl. *N,N*-dimethylformamide or in aqueous solutions neutralized with sodium bicarbonate. These drugs were also tested for their effect on: (1) the incorporation of sulphur-35 from sodium sulphate-^{35}S into tissue mucopolysaccharide sulphates by corneal and cartilage slices[10,11]; (2) the oxidation of octanoate-1-^{14}C to carbon dioxide-^{14}C by cartilage slices[11]; (3) the incorporation of phosphorus-32 from sodium orthophosphate-^{32}P into organic phosphates by cartilage slices incubated in a Krebs–Ringer type buffer solution constituted with *tris* hydrochloride, *p*H 7·4. The incubated tissue slices were digested with papain[11] to release non-protein constituents. Inorganic phosphate-^{32}P was precipitated together with added non-radioactive orthophosphate, *p*H 7·4, by magnesium and ammonium ions at 4° and *p*H 9·2, leaving the bulk of the organic phosphates in solution. 1,2-Diphenyl-3,5-dioxo-4(3′-hydroxybutyl)-pyrazolidine, a metabolite of phenylbutazone (metabolite II), was freshly prepared from the tautomeric lactone, δ-caprolactone-α-carboxylic-*N,N*′diphenylhydrazide (*G* 28,423) by treatment with alkali[12].

Table 1 shows that the relative activity of these drugs and some of their chemical analogues as inhibitors of phosphate and sulphate metabolism by cartilage slices *in vitro* parallels their activity as uncouplers of oxidative phosphorylation and agrees with their relative potencies as anti-inflammatory agents, where this is known[6,13,14]. More hydrophilic analogues of these antirheumatic drugs such as their principal *in vivo* metabolites (oxyphenbutazone), 'stripped down' chemical analogues (anthranilic acid, isonicotinic acid) or a glycoside (glycyrrhizin) were in all cases less potent drugs *in vitro*; the only exception being 3-hydroxycinchophene, which is also an analogue of salicylic acid, in contrast to cinchophene itself. Rendering salicylic acid more lipophilic by conversion to its anilide greatly enhanced its activity *in vitro*, not associated with the anilide group *per se* (cf. benzanilide). These relationships fully support the generalization that the activity of anti-inflammatory drugs is intimately associated with their lipophilic character[10] and are reminiscent of the Meyer–Overton hypothesis for narcotic action.

Only phenylbutazone, flufenamic acid and salicylanilide at concentrations which inhibited sulphate metabolism by more than 50 per cent inhibited octanoate oxidation by cartilage to any significant degree. The following isoprenoids, which contain one or more of the functional groups of the glycyrrhetinic acid molecule, neither uncoupled oxidative phosphorylation in liver mitochondria nor inhibited cartilage metabolism at 5×10^{-5} M: oleanolic acid, *O*-acetyl oleanolic acid, morolic acid, cholest-4-ene-3-one, deoxycorticosterone (DOC), menthol. This inactivity of DOC suggests that the mineral corticoid activity of glycyrrhetinic acid[4] is largely dissociated from its anti-inflammatory properties.

RADIOBIOLOGY

Sensitization of Radio-resistant Bacteria to X-rays by Iodoacetamide

IODOACETATE has been shown to sensitize animals[1,2], cells in tissue culture[3] and bacteria[4] to X-rays. We have found[5] using iodoacetamide that the sensitization was particularly marked with the more radio-resistant bacteria.

Bacterial cells were suspended in 0·1 M phosphate buffer *p*H 7·0 and iodoacetamide added to give a concentration of 10^{-3} M or less. Exposure to iodoacetamide at 10^{-3} M alone for a period of 1 h caused no cell inactivation. After 20-min treatment with

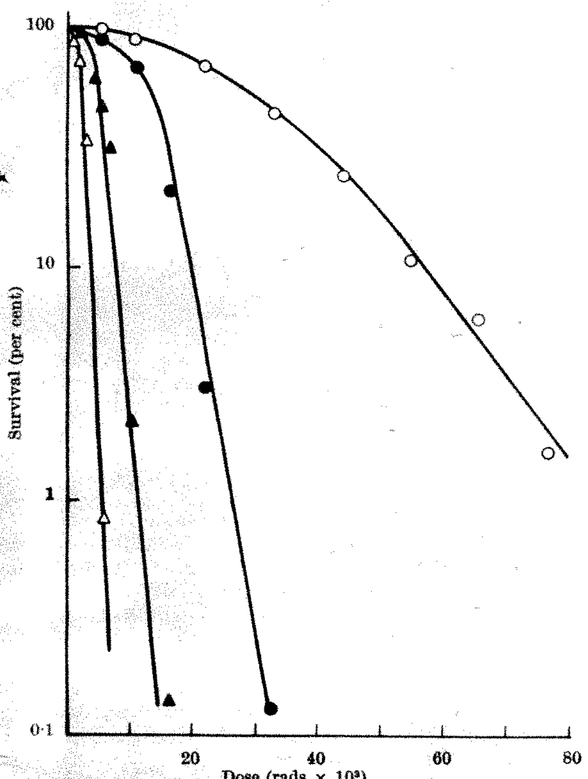

Fig. 1. Effect of iodoacetamide (added to the phosphate buffer in which the organisms were suspended) on the inactivation by X-rays of *Micrococcus sodonensis*. ○, No iodoacetamide; ●, 10^{-4} M iodoacetamide; ▲, 3×10^{-4} M iodoacetamide; Δ, 10^{-3} M iodoacetamide

iodoacetamide at room temperature samples were irradiated under controlled gas conditions with 220 kVp X-rays. The dose-rate was $1{\cdot}1 \times 10^3$ rads/min. Survivors were estimated by the surface viable count technique[6] on 'Oxoid' nutrient agar.

In aerated conditions we found no sensitization of *E. coli. B* by 10^{-4} M iodoacetamide. With *Pseudomonas fluorescens* there was a slight increase in sensitivity but the slope of the exponential survival curve was increased by not more than 10 per cent. With *E. coli B/r*, however, there was a marked increase in sensitivity. Not only was the initial shoulder of the survival curve decreased but there was also an increase in the slope of the exponential part. The lethal dose (expressed as dose required to give 37 per cent survival, D_{37}) was decreased from 13 krads to 6 krads, a dose enhancement factor of approximately 2·2. Both the initial shoulder and the final slope were equally affected in *Micrococcus sodonensis* (Fig. 1). The degree of sensitization was increased by raising the concentration of iodoacetamide; the dose enhancement factors being 2·6, 5·8 and 12·6 for concentrations of 10^{-4}, 3×10^{-4} and 10^{-3} M iodoacetamide respectively. At the highest concentration used (10^{-3} M) the lethal dose was reduced from 38 krads to 3 krads. Under anaerobic conditions *Micrococcus sodonensis* was 2·0 times as resistant to X-rays than when irradiated in aerated conditions (based on the slope of the exponential part of the survival curve). Iodoacetamide also sensitized the organism under anaerobic conditions and the magnitude of the effect was approximately the same as in air, that is, 10^{-4} M iodoacetamide reduced the anaerobic D_{37} from 89 krads to 39 krads, a factor of 2·3.

Micrococcus radiodurans, an organism exhibiting extreme radio-resistance, showed a very great increase in sensitivity when exposed to iodoacetamide during irradiation (Fig. 2). In air 3×10^{-4} M iodoacetamide reduced the lethal dose (D_{37}) from 263 krads to 37 krads and with 10^{-3} M iodoacetamide it was reduced to 3 krads. At the latter concentration the dose enhancement factor was nearly 90, and again both the initial shoulder and the slope of the final exponential curve were reduced.

Although the time and temperature of treatment with iodoacetamide before irradiation did not influence the sensitization of *Micrococcus sodonensis*, the effect was lost if the iodoacetamide was removed immediately before irradiation by dilution into buffer at 0° C. The addition of iodoacetamide immediately after irradiation produced no sensitization. Suitable experiments showed that the increased cell inactivation was not due to toxic irradiation products of the iodoacetamide produced in the external medium. Apparently the only condition necessary to obtain sensitization was the presence of iodoacetamide in the buffered suspension during irradiation.

We have no explanation to offer for the mechanism of sensitization of these resistant organisms to X-rays by iodoacetamide, but biochemical investigations indicate that the action may involve the cell membrane. In addition to sensitizing the inactivation of cells, two radiation-induced biochemical changes, namely the bleaching of the yellow pigment in *Micrococcus sodonensis* and the reduction in the oxidation of pyruvate by this organism, were considerably enhanced if the irradiation was carried out in the presence of iodoacetamide. As in the case of cell inactivation, iodoacetamide by itself had no effect on pyruvate metabolism or the pigment. From spectrophotometric data the extinction of the pigment was reduced by 50–60 per cent for a dose of 110 krads given in the presence of 10^{-3} M iodoacetamide, but only by 10 per cent in its absence.

The oxidation of pyruvate measured manometrically was reduced by less than 10 per cent with a dose of 110 krads. When 10^{-4} M iodoacetamide was present during irradiation the oxygen consumption was reduced by 58 per cent. On the other hand, the

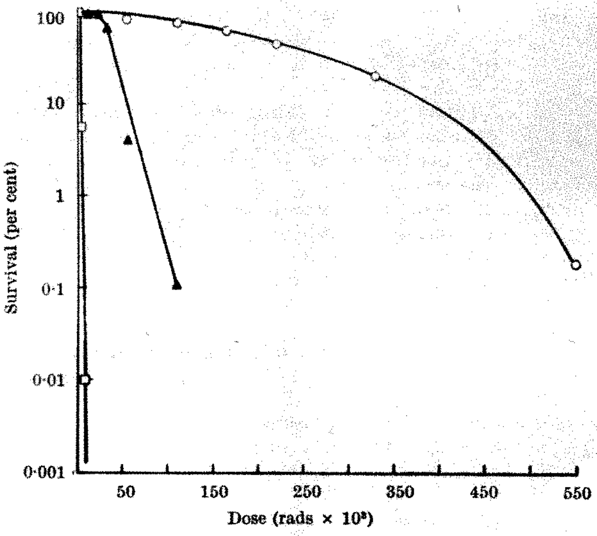

Fig. 2. Effect of iodoacetamide on the inactivation by X-rays of *Micrococcus radiodurans*. ○, No iodoacetamide; ▲, 3×10^{-4} M iodoacetamide; □, 10^{-3} M iodoacetamide

degradation of DNA, measured viscosometrically, in samples extracted from *E. coli B/r* immediately after irradiation was not influenced by the presence of iodoacetamide.

We thank Dr. S. E. Jacobs for advice and facilities given to us at the Imperial College of Science and Technology.

Influence of X-rays on the Incorporation of Deoxyribonucleic Acid Precursors into some Mammalian Cells *in vitro*

Dose-response curves for the influence of ionizing radiations on *in vitro* incorporation of DNA precursors into human bone marrow[1] and experimental tumours[2,3] irradiated in the period of synthesis of DNA are well known. Recently published investigations[4] showed a striking similarity between these curves for human bone marrow and Ehrlich ascites carcinoma while both systems were oxygenated. Our experiments show the relationship between the dose of X-rays and the depression of thymidine incorporation in anoxic suspensions of rat bone marrow and Ehrlich ascites tumour.

The suspensions[5] contained an average amount of $2 \cdot 4 \times 10^7$ nucleated bone marrow cells together with $0 \cdot 7 \times 10^7$ erythrocytes or $1 \cdot 1 \times 10^7$ tumour cells in 1 ml. of medium, consisting of 50 per cent of supplemented Hanks's solution and 50 per cent of rat serum. The suspension of cells was irradiated in room temperature with X-rays, 160 kVp, dose-rate of 140 r./min. Thymidine-2-^{14}C, 0·75 μc./ml. culture, specific activity 16·0 or 18·3 mc./mM, was added immediately afterwards. 2-ml. aliquots of cell suspension were incubated at 37·5° C in a number of screw-cap bottles for 2 h without shaking. After incubation the cells were washed twice in ice-cold solution of 0·85 per cent sodium chloride and once in a 2 per cent acetic acid. Each time the cell suspension was centrifuged for 10 min at 0° C (2,000*g*). Finally, the sediment was suspended in 2 ml. of 2 per cent acetic acid and three aliquots of 0·3 ml. were placed in aluminium planchettes. A windowless gas-flow counter was used for measuring the activity. The mean values of the experimental groups were expressed as a percentage of the control group. For each dose 4–6 separate experiments were carried out. Standard deviation of individual experiments are indicated on the graph (Fig. 1). The tendency of the resulting curves to converge allowed us to draw a common curve for both tissues.

In the foregoing experiments both systems are anoxic: the suspension of Ehrlich ascites tumour cells does not contain red blood cells; the ratio of erythrocytes to nucleated bone marrow cells is about 1 : 3, while Berry *et al.*[4] added 50–100 red blood cells for each tumour cell to the suspensions so as to oxidize the cells of Ehrlich carcinoma. The same X-ray dose-response curves for the inhibition of incorporation of thymidine were obtained even though the compared suspensions contained cells that were taken from two species of animals and were of a different tissue character, one being a rather homogeneous population of tumour cells of epithelial origin, and the other normal, inhomogeneous, hæmopoietic tissue. Finally, they also differ in the rate of incorporation of thymidine that was found in other experiments[6] in which irradiation was not performed.

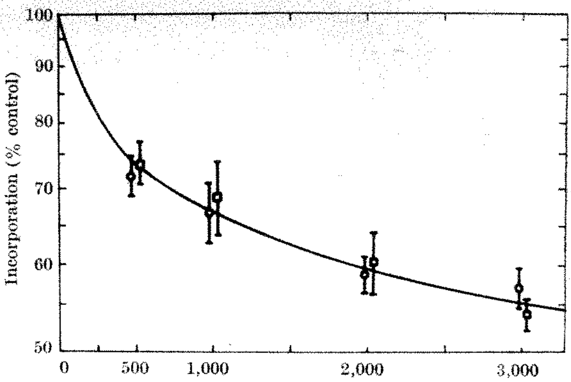

Fig. 1. Dose–response curve for X-rays on incorporation of thymidine-2-^{14}C into rat bone marrow and Ehrlich ascites tumour cells *in vitro* (S period). □, Bone marrow; ○, Ehrlich ascites tumour

This lack of specificity of X-ray action on incorporation of thymidine into different tissues depends probably on the environment of the cell. The kind of serum used seems to be an important factor. Berry, Hell, Lajtha and Ebert obtained similar results testing oxygenated suspensions of human bone marrow and Ehrlich ascites tumour cells; in both cases they used human serum. Lajtha[7], on the contrary, noticed changes in the effect of X-rays on synthesis of DNA induced by various sera. This may account for the differences between dose-response curves for Ehrlich carcinoma obtained by Berry *et al.*[2] and by us.

BIOLOGY

Tumour Induction by an Indolyl-3-Acetic Acid–Kinetin Interaction in a *Nicotiana* Hybrid

It has been demonstrated that auxins influence the ability of bacteria to induce plant tumours[1], and that kinetin in the presence of auxin can substitute for extracts of tumours in the production of tumours on isolated tobacco pith tissue[2].

Table 1. EFFECTS OF SEVERAL GROWTH FACTORS* ON TUMOUR FORMATION AND GROWTH OF THE HYBRID, AMPHIDIPLOID *Nicotiana suaveolens-langsdorffii*. PLANTS WERE TREATED 16 DAYS AFTER SEEDING AND SCORED 15 DAYS AFTER TREATMENT

Treatment	No. of plants	Plants with tumours (per cent)	Mean length of second leaf (mm) ± *S.D.*
Control	14	0·0	40·0 ± 5·6
IAA	12	8·0	—
Kinetin	16	44·0	—
GA	14	7·0	59·0 ± 6·8
IAA + kinetin	14	86·0	40·0 ± 6·6
IAA + kinetin + GA	12	92·0	48·0 ± 5·2
*p*CiBA	12	0·0	—
IUDR	14	0·0	

* Micromoles of each growth factor applied per seedling: $4{\cdot}70 \times 10^{-4}$ μm IAA, $1{\cdot}53 \times 10^{-3}$ μm kinetin, $2{\cdot}14 \times 10^{-3}$ μm GA, $4{\cdot}7 \times 10^{-4}$ μm *p*CiBA, and 1×10^{-3} μm IUDR.

It was of interest to determine whether spontaneous genotypically determined tumour formation in *Nicotiana* hybrids[3] involves the same or similar hormonal and biochemical alterations as occur in tumours induced by the crown-gall bacterium. Earlier work with *Nicotiana* species and crosses[4] has shown that the hybrid, amphidiploid *N. glauca-langsdorffii*, has a higher free auxin-level as well as a greater capacity for the conversion of tryptophan to auxin than the parental species. This report describes the interaction of indolyl-3-acetic acid (IAA), 6-furfurylaminopurine (kinetin) and gibberellic acid (GA) on tumour induction in seedlings of the interspecific hybrid, amphidiploid *Nicotiana suaveolens-langsdorffii*.

The tobacco seedlings were grown aseptically in 125-ml. Erlenmeyer flasks containing 1 per cent agar and a modified Hildebrandt–Riker nutrient medium[5] with 'Versene'-chelated micronutrients. The plants were maintained in cotton-stoppered flasks in a constant temperature chamber at 22° C, with an 18-h photo-period at 600–650 ft.-candles. Seedlings 16 days old, including the controls, were pre-treated with 1 drop of 0·1 per cent 'Tween-20' surfactant for 1 h after which the excess was removed with sterile cotton. The seedlings were then treated separately and in several combinations with IAA, kinetin, GA, *p*-chlorophenoxyisobutyric acid (*p*CiBA) and 5-iododeoxyuridine (IUDR). The growth-factor solutions containing IAA and kinetin as well as the 'Tween-20' were prepared in White's basal inorganic medium[6] as a carrier. The solutions were adjusted to *p*H 4·5 and autoclaved for sterilization. The heat-labile compounds, GA, *p*CiBA and IUDR, were added aseptically to the mineral-growth-factor mixtures after autoclaving. Measured volumes (5 μl.) of the growth factors were applied aseptically over the leaf axils enclosing the shoot apex. Care was exercised to avoid wounding the apex and the surrounding tissues.

As shown in Table 1, kinetin in the presence of IAA exerts a strong influence on tumour induction in these *Nicotiana* seedlings. Spontaneous tumours usually form on the plants only late in development subsequent to flowering. The treatment results clearly show a synergistic effect of IAA and kinetin. IAA and GA alone exert little effect on tumour induction. The IAA–kinetin mixture partially suppresses excessive elongation caused by GA. This is illustrated in Table 1 by the measurements of the length of the second leaf. Tumour induction by kinetin alone may reflect an IAA–kinetin interaction with endogenous IAA. It may be that kinetin interacts with IAA to interfere with normal apical control since the IAA–kinetin-treated seedlings seldom produce a normal apex. The anti-auxin *p*CiBA and the nucleic acid analogue IUDR obviously had no effect on tumour induction at the concentrations used.

The foregoing results from IAA and kinetin treatments suggest that hormonal interactions may be involved in tumour formation on genetically tumour-conditioned plants. The synergistic role of IAA with kinetin in the *Nicotiana* hybrid system and the fundamental role of IAA in the bacterially induced tumour system suggests that the two systems may be basically similar. This system, however, does not require wounding, and seems uniquely suited for future investigations in various aspects of plant tumour induction and development as well as for research on metabolic inducer phenomena as they relate to differentiation and morphogenesis in plants.

Numerous possibilities exist for the function of the IAA–kinetin interaction in the formation of the hybrid tobacco tumours. One is that kinetin may act directly as a purine analogue causing the production of abnormal nucleic acids and cellular proteins. Perhaps a better argument would be that the IAA–kinetin treatments elicit the production of a variety of cell constituents in the hybrid which can induce tumours and that precursors for similar compounds are lacking or are diverted in the parental species. This concept is supported by the findings that kinetin in the presence of IAA stimulates the production of certain specific compounds which may function in governing morphogenesis and development[7]. The natural cell metabolites produced during development, which mediate morphogenesis and differentiation, are believed to be concerned with the repression of certain specific components of the total genetic potential[8,9]. By an extension of this hypothesis, the IAA–kinetin treatment can be viewed as affecting the synthesis or activation of certain cell constituents which interfere with the action of normal repressors. Metabolic antagonists to normal repressors could have a direct effect on the synthesis of messenger RNA and consequently on proteins concerned with differentiation from meristematic cells.

Methylcholanthrene-induced Lymphosarcomas in *Xenopus laevis*

THE number of spontaneous neoplasms found in Amphibia[1] and the success of Leone[2,3] in chemically inducing tumours in newts uphold the view[4] that Amphibia, like other vertebrates, are susceptible to the occurrence of neoplastic growth.

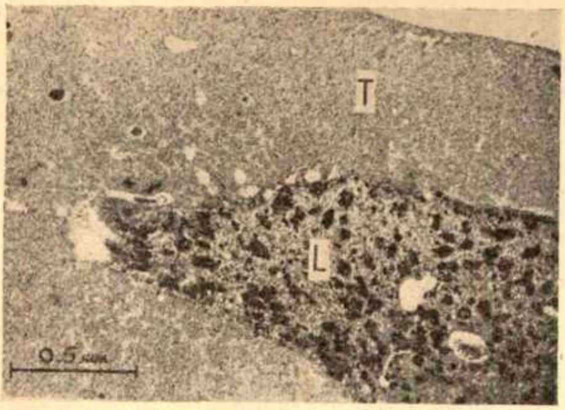

Fig. 1. Case 2, showing an unpigmented, vacuolated mass of lymphoid cells (*T*) around the pigmented liver tissue (*L*), which also contained many tumour cells. (Stained with hæmatoxylin and eosin)

Attempts at the chemical induction of tumours in Amphibia have, until recently, been unsuccessful. Thus Lucké and Schlumberger[5] were able to conclude that there was no convincing evidence that true neoplasia had been induced by the chemicals used. However, the success of Breedis[6] and Leone[3] in obtaining sarcomas in newts, using methylcholanthrene, and that of Briggs[7] with the anuran *Rana pipiens* indicate that this topic should be re-investigated.

Experiments have been performed in an attempt to induce neoplasia in adult *Xenopus laevis* using methylcholanthrene. Single doses of the chemical were given, either by injection in sterilized arachis oil into the dorsal lymph sac, abdominal cavity, thigh muscle or under the skin (14 animals), or by the implantation of the crystals alone into the dorsal lymph sac (12 animals).

The results of the experiment in which methylcholanthrene was given with oil are summarized in Table 1. The first individual (case 1) became emaciated and was killed 263 days after the injection. The kidneys were enlarged and yellow, while the enlarged liver was covered with white nodules. Microscopical analysis showed that the kidney, liver and spleen were being actively infiltrated and destroyed by masses of small, spheroidal cells the nuclei of which stain deeply and in which the amount of cytoplasm is very small. Fig. 1 shows the appearance of the liver in another animal (case 2), which was killed 384 days after injection and showed infiltration of the kidney, liver, oviduct, spleen and bladder by the same type of cells as observed in case 1. Four other animals, including 1 control, showed lymphoid tumours of varying degrees of development. No evidence of neoplastic change was found in 7 of 8 control animals injected with oil alone or in the other 5 experimental animals. The lipogranulomatous reaction observed in four of the latter group was probably due to the combined effect of oil and carcinogen, since no such reaction was found in the controls.

Two cases of lymphosarcoma were found among the 12 animals given methylcholanthrene crystals alone. One animal bore many nodules on the floor of the dorsal lymph sac when it was killed 365 days after crystal implantation. The nodules were composed of lymphocytes, which were also invading the kidney, liver, spleen and rectum. A small, yellow bump in the dorsal skin of the second animal was found to consist of lymphocytes, which had destroyed the glands of the dermis and were invading the epidermis and dermal muscle.

Table 1. EFFECTS OF INJECTING METHYLCHOLANTHRENE IN OIL

Case	Sex	Injection site	Days after injection	Tumour sites	Diagnosis	Total No. of cases
1	F	UAS	263	liver, kidney, spleen	transplantable lymphosarcoma	2
2	F	UAS	384	liver, kidney, oviduct, spleen, bladder		
3	M	UAS	83	lung, liver	lymphosarcoma	2
4	F	AC	384	lung		
5	F	DLS	388	kidney	probable lymphosarcoma	2
6	F	AC control	385	liver, lung		
7–15 plus 7 controls	—	—	78–484	—	negative	16

UAS, Under abdominal skin; AC, abdominal cavity; DLS, dorsal lymph sac.

The induced tumours appeared to be histologically very similar to the spontaneous lymphosarcomas previously described in *Xenopus*[1] and invaded similar sites, particularly the liver and kidney. Small fragments from three of the induced tumours were successfully transferred to other hosts. During the experiments no spontaneous lymphoid tumours became evident in any other of the one thousand adult animals of the colony.

Since most of the positive results in these experiments were found more than 300 days after the introduction of the chemical, it may be that earlier attempts[8,9] using methylcholanthrene with Amphibia have failed because the animals died too soon after injection and long before any neoplastic change had taken place. Furthermore, the proximity of the carcinogen to the host cells would vary with the viscosity of the oil injected with it, the viscosity depending on the temperature of the host itself. Since amphibians live at the temperature of their external environment and their maximum length of life varies from 10 to 40 years, it does not necessarily follow that the results of experiments using these animals would be the same as those using laboratory mammals. Indeed, Leone[3], who induced lymphosarcomas in newts (*Triturus cristatus*), found that lesions developed at the site of methylcholanthrene implantation 1–3 months later, and metastases, usually to the liver and spleen, 3–5 months after implantation. The difference in latent period in Leone's and the present experiments could be an expression of a difference between the urodele and anuran amphibia.

The results of these experiments with the anuran *Xenopus laevis* support the conclusion of Leone[2,3] that the implantation of methylcholanthrene into Amphibia leads to the development of sarcomas.

I thank Prof. M. Fischberg for his advice. This work was supported by grants from the Medical Research Council (U.K.) and the Fonds National Suisse pour la Recherche Scientifique.

Manatees of Guiana

Having recently returned from a conservation survey of manatees in British Guiana, we now put forward our views about the present status of these animals and their suggested deliberate use for the clearance of weeds from artificial waters. More detailed information will be published elsewhere.

American manatees still live, but in small numbers, in many places around the Gulf of Mexico and the Caribbean Sea. The sub-species on the coasts of Central and South America is *Trichechus manatus manatus*, while *T. manatus latirostris* is found on the Florida peninsula. Both sub-species occur in the coastal rivers and in the sea and both grow to a length of about 10–11 ft. and a weight of about 1,000 lb.

In British Guiana the manatees live primarily in the rivers of the coastal plain. Nowhere can they be said to be abundant: nor should they be described as rare, though they are certainly less frequently seen than formerly, suggesting greater scarcity. The increasing use of powered boats, including dug-out canoes with outboard engines, is probably scaring the animals away from many reaches of the rivers and so restricting their distribution. Also they are far from being immune from casual slaughter for food despite the protective legislation so wisely introduced in 1961. But they have not, in recent times, been deliberately hunted to an important degree, though at earlier dates it seems that they suffered an active fishery.

Venezuela probably also contains a considerable stock of these manatees, but information from here and from countries farther west is inadequate. Surinam has fewer than British Guiana and farther east the coastal plain disappears and there are no suitable rivers. In the Amazon Basin the formerly large stock of *Trichechus inunguis* seems to be sadly depleted following regular hunting for meat and hides which probably still continues. This is a smaller animal which seems to be restricted to fresh water.

Little information about the life-history of *T. manatus manatus* is yet available and it is now difficult to obtain without unsuitable and deliberate killing. It seems that the animals are slow breeders: young are very rarely seen. Evidence from captivity suggests longevity. In habits manatees are shy and unobtrusive, unable to leave the water and only appear at the surface to breathe, feed or occasionally lie at rest. They feed entirely on vegetable matter, which may be rooted on the bottom, floating on the surface or growing on the banks close above the water. They are largely unselective in their feeding and will eat any plants which are soft enough to be torn off by the muscular lips. Manatees tend to be gregarious.

In 1960 Mr. W. H. L. Allsopp, British Guiana fisheries research officer, directed attention to the fact that in certain circumstances manatees could be used for keeping water channels clear of both floating and standing vegetation[1]. This revival of interest in these animals received world-wide publicity, for it coincided with the problem of excessive weed growth in the new Lake Kariba. There grew up much exaggerated views on the useful potentialities of manatees as weed clearers if translocated to distant lands. However, for large areas of water the numbers needed to have any significant effect would seem to make the idea quite unrealistic. The picture began to be restored to its proper perspective by the publication of a paper by the Fisheries Division of the U.N. Food and Agriculture Organization in 1961[2].

Yet under particular conditions in British Guiana the local manatees are beginning to prove themselves efficient in weed clearance. They are being so used by the Department of Drainage and Irrigation on an experimental basis; and following a programme initiated by Mr. Allsopp, some seventy individuals have been caught since 1959 and introduced into channels varying in width from about 6 ft. to 60 ft. Reports on their performance are encouraging, and catching on a small scale continues. Further, in the Georgetown Waterworks two large ponds, about 150 and 250 yards by 15 yards, have been kept completely clear since 1950 by three manatees. However, the number of waters where these animals can be used efficiently is very limited, for they are easily disturbed by traffic and vulnerable to illicit human attack in restricted areas. The need to use the water channels for transporting cane makes it impracticable to use manatees in the sugar plantations.

Though potentially economic in a limited number of water ways, this use of manatees is at present all too expensive from the point of view of the stock. Despite improvements in technique, the losses in catching and transport are high. But even more important is the fact that there has been no breeding (apart from occasional births in the Georgetown Botanical Gardens some decades ago). Until this serious deficiency can be overcome, and manatees can be induced to breed regularly in a state of semi-domestication, the large-scale use of these animals for weed clearance cannot be sensibly recommended. Although the British Guiana stock may be able to survive under present pressures, it certainly could not stand the removal of large numbers of expendable individuals.

Effect of Skeletal Muscle Homogenates on the Differentiation of the Chick Chorio-Allantoic Membrane

The hyperplastic and metaplastic effects of muscle homogenates and muscle extracts on the chorio-allantoic membrane of the chick have recently been the objects of a number of investigations[1-4]. Van Haefton contends that cell-free muscle homogenates pipetted on to the chorio-allantoic membrane can induce the development of non-striated 'myocytes' within the mesoderm of the membrane[3]. Ebert[1] has also reported the induction of occasionally striated 'muscle' cells following the introduction of ribonucleic acid extracted simultaneously from chicken cardiac muscle and Rous sarcoma virus. Ebert recognizes the possibility that van Haefton has observed the proliferation of cells remaining in the 'cell-free' homogenate rather than a response of the membrane itself[5]. Wilt and Stolz[4] have recently repeated the experiments of van Haefton with similar results. They conclude that the non-striated, oriented, elongated cells found within the chorio-allantoic membrane mesenchyme are of host rather than graft origin, thereby representing a genuine response of the chorio-allantoic membrane to components of the muscle homogenate. They further conclude that

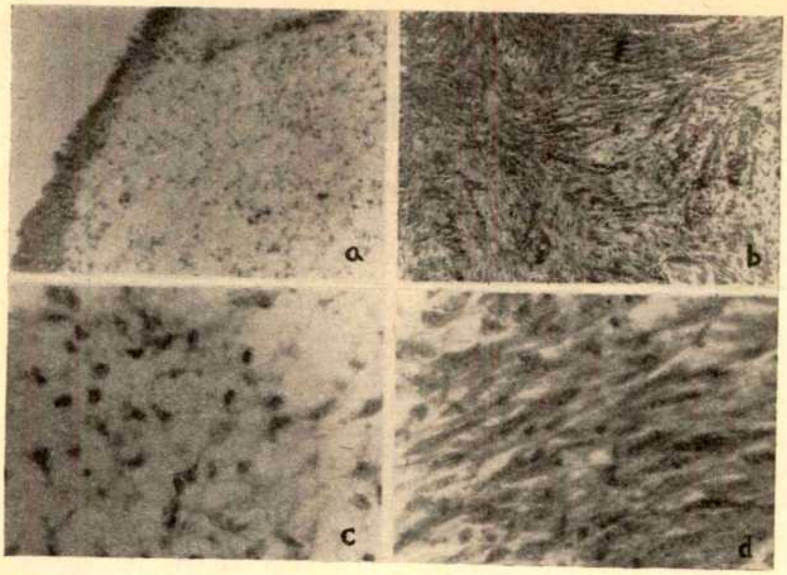

Fig. 1. *a*, Section through the normal chorio-allantoic membrane showing the chorionic epithelium at the left and mesenchyme cells to its right (× *c*. 50); *b*, elongated, oriented cells in the chorio-allantoic membrane mesoderm following treatment with muscle homogenate (× *c*. 50); *c*, mesenchyme cells of the normal chorio-allantoic membrane (× *c*. 200); *d*, induced response in mesoderm of chorio-allantoic membrane seven days after treatment with muscle homogenate (× *c*. 200)

present evidence does not justify statements regarding the nature of the response.

In our experiments homogenization of adult chicken breast muscle for injection on to the chorio-allantoic membrane was as follows: after sterile excision small pieces of muscle were blended with chick Ringer's solution for 25 min in a Waring blender at 4° C. 1 c.c. of this preparation contained 0·09 g of muscle by dry weight. The preparation was alternately frozen and thawed ten times and finally homogenized for 10 min in a motor-driven micro-homogenizer. Microscopical examination of the homogenates revealed the presence of nucleated cell fragments; however, intact cells were not found.

Under sterile conditions, the eggs of White Leghorn chickens were fenestrated on the eighth or ninth day of development. By means of a hypodermic syringe a well-vascularized area of the chorio-allantoic membrane was injected with 0·3–0·5 c.c. of the muscle homogenate. Control embryos were injected with 0·3 c.c. of sterile Ringer's solution. All eggs were sealed with a glass window and re-incubated for 7 days. At the end of this time the eggs were re-opened, the embryos were examined for grossly visible defects, and pieces of the membranes in the region of the homogenate were recovered for histological examination.

Of 36 control embryos, 24 (67 per cent) survived until the completion of the experiment. Histological examination showed that none of these survivors had a chorio-allantoic membrane with elongated, linearly oriented mesoderm cells. Of 70 experimental embryos, 11 (16 per cent) survived for 7 days after treatment with the homogenate. All these exhibited characteristics similar to those described by van Haefton[3] and Wilt and Stolz[4]. 'Non-specific' responses of the experimental membranes generally included vascular invasion of the chorio-allantoic membrane adjacent to the site of the homogenate; proliferation and stratification of both the ectodermal and endodermal epithelia; and metaplastic changes, typically cornification and erosion, in the chorionic epithelium. Mesodermal hyperplasia was also marked and occasional mesenchymal invasion by epithelial 'pearls'[3,6] was noted.

In addition to these 'non-specific', the chorioallantoic membrane of 6 (54 per cent) of the surviving experimental embryos exhibited a mesenchymal metaplastic change comparable with those considered 'muscle-specific' by Ebert[1] and van Haefton[3]. Groups of mononuclear mesenchymal cells became elongated and linearly oriented, lying parallel to the surface of the membrane. Consistent with other experiments of this type[3,4], the presence of cross-striations was never noted. Fig. 1 illustrates the kind of change occurring in the mesoderm of the chorio-allantoic membrane.

Our results differ from those of other investigators[1,3,4] in that the mortality-rate of the experimental animals was very high; also a higher percentage of surviving embryos exhibited linearly oriented, elongated mesoderm cells in the chorio-allantoic membrane. It is possible that the freezing and thawing of the homogenate is responsible for both these differences. However, properly controlled experiments will be necessary to demonstrate this conclusively.

In conclusion, we agree with van Haefton[3] and Wilt and Stolz[4] that cell-free homogenates of adult chicken muscle can elicit a response from the chorio-allantoic membrane of the developing embryo. To define this response, on the basis of present evidence, as the induction of muscle tissue would be premature. We agree with Wilt and Stolz[4] that specific histochemical, immunological and biochemical tests are necessary to demonstrate a relationship between striated muscle cells and the cells found in the mesoderm of the chorio-allantoic membrane of the treated embryos.

Variation in Pathogenicity in the Cereal Root Eelworm

VARIATION in the pathogenicity of the cereal root eelworm (*Heterodera avenae* Wollenweber, 1924) was first demonstrated in Denmark by Andersen[1] using various barleys as differentials. Four of these barleys, No. 191, No. 14, Drost and Fero, with Rika as control, have been tested here against seven populations of the cereal root eelworm obtained from various parts of Britain.

Table 1. TOTAL NUMBER OF MATURE FEMALES OF THE CEREAL ROOT EELWORM FROM FIVE PLANTS OF EACH OF FIVE BARLEY VARIETIES IN SEVEN SOILS

Barley varieties	Cereal root eelworm populations 1	7	8	4	5	6	9
Rika (control)	796	1,581	2,018	1,390	2,245	1,964	1,949
Drost	0	94	183	860	2,215	1,358	1,501
Fero	0	95	209	1,245	2,068	1,753	1,133
No. 14	0	0	0	6	0	1	3
No. 191	0	0	0	5	0	0	2

The material was sown February 1962 in infested soil in pots in the glasshouse, and the number of mature cereal root eelworm females on the plant roots was counted in June 1962. The results are summarized in Table 1.

Clearly, Rika barley is susceptible to all seven cereal root eelworm populations, while No. 191 and No. 14 can be classed as resistant, although this resistance is not complete since a small number of females was found on some plants when tested against certain eelworm populations; but they never exceeded three on a single plant.

The reaction of Drost and Fero shows that there are differences in pathogenicity between some of the eelworm populations. These two varieties are resistant to population 1 of the cereal root eelworm but completely susceptible to populations 4, 5, 6 and 9, while to populations 7 and 8 their reaction is intermediate.

It also appears that there are genetic differences between the resistances of some of the barley varieties; this is being investigated.

I thank Mr. S. Andersen, Den Kgl. Veterinaer-og Landbohøjskoles, Copenhagen, Denmark, for his co-operation. This work was supported by an Imperial Chemical Industries, Ltd., research fellowship.

Influence of Hypophysectomy and of an Adrenocortical Inhibitor (*SU*-4885) on the Stress-Response of the White Blood Cells in the Teleost Fish, *Mollienesia latipinna* Le Sueur

PREVIOUS work has shown that stress by brief immersion in ice-water induces characteristic changes in the number of circulating leucocytes in the male killifish, *Fundulus heteroclitus*: at 20° C, an initial fall (leucopenia) 1 h after stress is succeeded at 2 h by an increase above the normal level (leucocytosis)[1,2]. Single injections of ACTH[3] produced leucopenia at low doses (0·15 I.U./g), and leucocytosis at higher doses[2]. Single injections of cortisol (5 μg/g), while causing leucopenia in regressed males and females, produced leucocytosis after 2 h in both breeding and hypophysectomized fish of either sex[1].

In the warm-water cyprinodont *Mollienesia latipinna*, injections of ACTH into intact adult males at 25° C induced leucocytosis at 4 h at all doses tried, the lowest being 0·075 I.U./g. Maximum leucocytosis (× 6) followed a dose of 0·15 I.U./g; 0·225 I.U. and 0·30 I.U. only doubled the white cell count. Control injections of 0·6 per cent sodium chloride produced mild leucopenia[4].

These earlier results suggested that the stress reaction was mediated by the pituitary-adrenal axis.

Table 1. WHITE BLOOD CELL COUNTS (MEAN NUMBER OF CELLS/MM^3, ± *S.E.*) OF *M. latipinna* FOLLOWING COLD SHOCK

	Group	Unshocked controls	Time after shock 1 h	4 h	6 h
A	Intact males	30,583 ±1,429	2,654* ±233	55,633* ±1,426	22,809† ±1,739
B	Intact males	31,408 ±4,535 (5 fish)	9,970* ±1,575	48,444‡ ±4,706 (5 fish)	24,020 ±2,863
C	Intact males in *tris*	27,746 ±2,241	7,796* ±766	45,320† ±3,280	27,793 ±1,833
D	Intact males in *SU* 4885	21,000 ±1,454	22,716 ±3,096	21,486 ±3,073	18,313 ±1,817
E	Hypophysectomized males	12,246 ±2,033	5,327† ±1,443	8,014 ±639	9,119 ±1,250

Each value is the mean for 7 fish except where indicated. In comparisons with unshocked controls, t tests showed:

* Highly significant, P = 0·001 or less.
† Significant, P = 0·001 – 0·05.
‡ Barely significant, P = 0·05 – 0·1.

In work reported here we have pursued the matter by investigating the response of male *M. latipinna* to cold-shock, using intact fish, hypophysectomized fish, and fish treated with the drug *SU*-4885 (Ciba), which has been shown to inhibit the 11-hydroxylation enzyme system of the mammalian adrenal cortex with little or no toxic or other endocrine effects[5-7,11].

Adult male fish were shipped from Florida through a local dealer, and were acclimatized to laboratory conditions for at least two weeks before being used in an experiment. Since hypophysectomized *M. latipinna* survive for only 2 days in fresh water[8,14], all the fish were kept in dilute sea-water (12 parts per thousand) at 25 ± 1° C, so that results from hypophysectomized fish could be compared with results from the other groups. The fish were stressed by being plunged into ice-water at 0–1° C; after 2 min. they were returned to 25° C in individual flasks and killed at various intervals. At autopsy the fish were anæsthetized in *MS* 222 (1 : 2,000), sexual maturity was confirmed, the pericardial cavity opened and blotted dry, and blood obtained by cardiac puncture from the auricle. The blood was withdrawn into a fine heparinized glass pipette by oral suction, transferred to a measuring pipette[9], diluted with the fluid of Reese and Ecker, and cell counts made in the standard way using a counting chamber.

The arrangement of the experiments is summarized in Table 1. The hypophysectomized fish (group *E*) had been operated two weeks previously, and intact fish of the same dealer's batch served as their controls (group *B*). The drug-treated fish (group *D*) and their controls (group *C*) were set up as follows. *SU*-4885 was available[10] as a solution of the ditartrate (100 mg/ml.), and was administered by adding it to the aquarium water at a rate of 1·5 ml./l. This produced an acid solution which was restored to approximately pH 7·6 by adding 7 ml./l. of a 0·2 M solution of *tris* (2-amino-2-hydroxymethyl-1,3-propanediol). This solution then contained approximately 150 mg *SU*-4885 ditartrate per litre. Assuming equal distribution between the fish tissues, this represented a dose of about 150 μg/g bodyweight. One-tenth of this dose in man promptly reduces the adrenal output of cortisol[11], and doses up to 320 μg/g in the rat have been shown to be without side-effects on the sex organs, thyroid gland, liver and growth, and had no anæsthetic properties[12]. At the dose used in our experiments, 2–4 days treatment was shown previously to result in histological evidence of hyperstimulation in the interrenal cells of *M. latipinna*, in comparison with *tris*-treated controls, presumably a consequence of enhanced ACTH-secretion following reduction in the

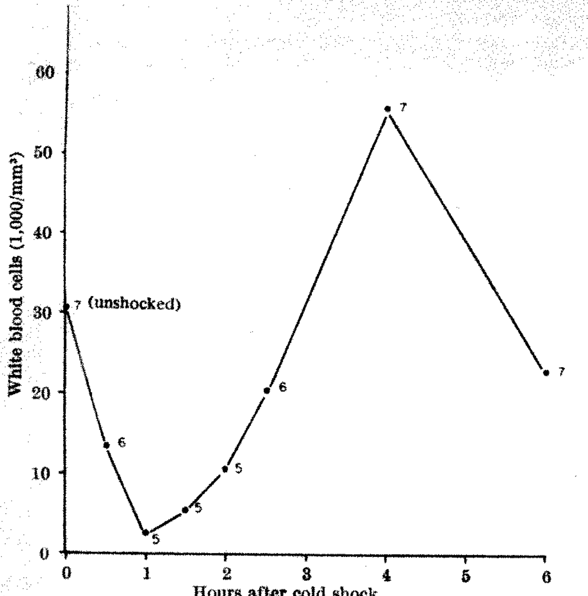

Fig. 1. Effects of cold shock on the white blood cell count of male *M. latipinna*. Number of fish at each point

output of 11-oxy-corticoids[13]. Fish were placed individually in flasks in the *SU*-4885 solution for 24–30 h before cold-shock and were returned to the same solution between cold-shock and autopsy. Control fish from the same dealer's batch were placed for the same period in flasks containing 7 ml. *tris*/l. adjusted to *p*H 7·6 by adding a small amount of tartaric acid.

Results of a detailed run with intact *M. latipinna* are shown in Fig. 1. Repetitions showed that though the actual numbers of leucocytes might differ between experiments, the pattern of the response remains the same: leucopenia followed by slight or marked leucocytosis (Table 1, groups *A*, *B*, *C*). Treatment with *tris* did not alter the response, but *SU*-4885 had marked effects, abolishing both the leucopenic and the leucocytic phases (Table 1). In contrast, and in agreement with the work on *Fundulus*[2], hypophysectomy abolished only the second phase and allowed leucopenia to be expressed at the usual time. It will be seen that hypophysectomized fish have much lower white cell counts than intact individuals. These counts can, however, be elevated by suitable stimulation, as evidenced by the leucocytosis induced in hypophysectomized *Fundulus* by ACTH and by cortisol injections[1].

Collateral effects of *SU*-4885 on pigmentation were also observed. The fish tended to darken, even on a white background, in the drug as compared with controls in *tris*: darkening commenced within a few hours and became more intense in 24 h. These changes coincided with the appearance of lethargy, suggesting mild anæsthesia, and since innervated melanophores of *M. latipinna* are not responsive to intermedin (MSH) or ACTH (ref. 14), the darkening probably depends on direct inhibition of the melanophore-concentrating innervation. However, faded denervated caudal bands[15] became more intensely darkened by treatment with *SU*-4885 than adjacent innervated areas. Since these bands are responsive to ACTH and to intermedin[14], this observation is most reasonably interpreted as indicating elevated ACTH-levels, the intrinsic melanocyte-stimulating hormone-like activity of the ACTH molecule being well known[16].

It is apparent from consideration of these results, together with the previous findings, that stress leucocytosis depends on the release of ACTH and a consequent increased output of 11-oxy-adrenocorticoids. Equally clearly, the leucopenic phase is independent of the pituitary. The abolition of leucopenia by *SU*-4885 but not by hypophysectomy is surprising, and may mean that this phase depends on the release of corticosteroids, presumably at a very low level, by some mechanism independent of pituitary ACTH. However, the slight narcosis observed in *SU*-4885-treated fish emphasizes the possibility that some non-adrenal action of the drug may be paramount in this phase. This matter is at present being investigated.

We are grateful to Dr. Grace E. Pickford for advice and criticism.

Growth Responses of *Avena* Stem Segments to Various Sugars

THE internodal extension which occurs in stems of grasses with onset of reproductive phase is a remarkably striking morphogenetic process[1], the causal basis for which has not been elucidated. We have been attacking this problem from several points of view, one of which is to culture excised stem segments on various substrates to assay by quantitative means the intercalary growth that occurs in internode portions of these segments. We wish to report here on the growth responses of *Avena* segments to a variety of sugars. It is quite possible that several of these may be directly implicated in intercalary growth of internodes of this plant *in vivo*.

Plants of *Avena sativa* L. cultivar Clinton were cultured in the greenhouse at a mean day tempera-

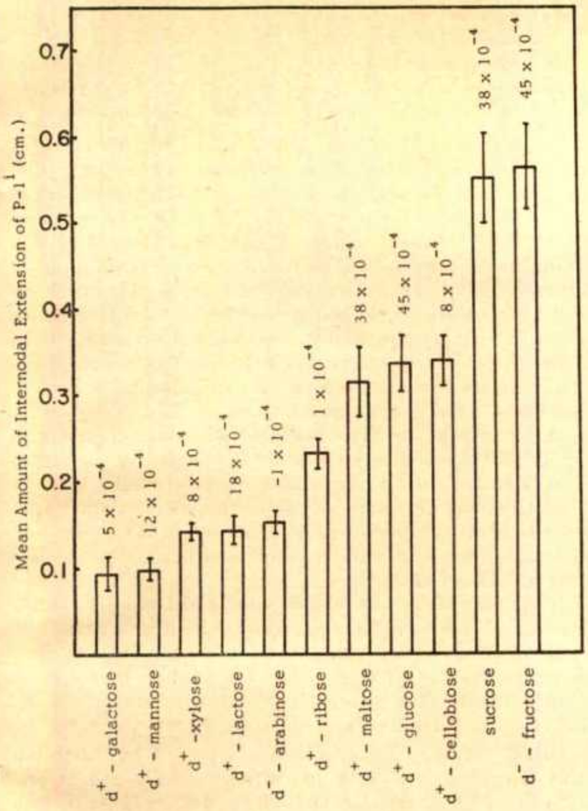

Fig. 1. Amount of internodal extension in $P-1^{n-i}$ segments cultured on various sugars (0·1 M) for 8 days in the dark. Change in dry weight per segment (g) is indicated above each bar of the histogram. The minus sign before net change for arabinose indicates loss in dry weight. *S.E.* for internodal extension data is shown for each sugar

ture of 80° F and a mean night temperature of 70° F under conditions of natural day-length. Plants (42 ± 2 days old) used for excision of stem segments were chosen from a population in which the majority of individuals showed evidence that the lamina of the last leaf had emerged from the sheath of the next oldest leaf. Segments utilized for culture studies were obtained when the internode ($P-1^i$) below the peduncular internode was 1·5–3·0 cm in length. This was done with the intent of incubating segments in which extension growth of this internode has essentially entered the phase of maximum rate of extension. We have found that 1-cm segments obtained when $P-1^i$ is in this length-range give a maximum internodal growth response in culture. Selection of shoots with $P-1^i$ in this length-range is done accurately with *Avena* shoots by observing the position of the peduncular node within the sheath of the leaf that surrounds this node. This node is darker (due to higher chlorophyll density) than the internodes above and below it and thus appears as a dark band when light is allowed to pass through the shoot. The 1-cm stem segments ($P-1^{n-i}$) utilized in our experiments include the base of $P-1^i$ and its associated node ($P-1^n$), an axillary bud, and sheath portion. We have found that the surrounding sheath portion does not elongate appreciably in culture, but the internode portion does. Thus the amount of extension of the latter can be measured to ascertain its growth response in various substrates and environments.

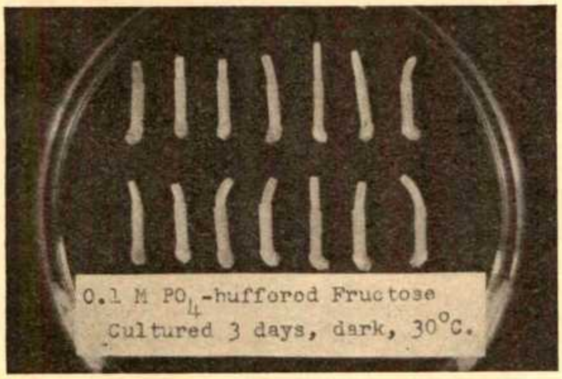

Fig. 2. Growth response of *Avena* $P-1^{n-i}$ stem segments cultured on 0·1 M PO_4-buffered fructose (× *c.* 0·75)

Excised segments (1 cm long) were surface-sterilized *en masse* by immersion in 10 per cent 'Clorox' (sodium hypochlorite) for 5 min. After draining off excess 'Clorox', segments were transferred under sterile conditions to plastic Petri dishes containing 20 ml. liquid medium. 30 segments were used for each treatment. After a 3- to 8-day incubation period at 25° C in the dark, internode-lengths were measured and dry weights of segments obtained.

Fig. 1 illustrates the amount of internodal extension and changes in dry weight for $P-1^{n-i}$ segments cultured on various sugars (0·1 M, phosphate–citrate buffer, *p*H 5·0) for 8 days in the dark. 0·1 M concentration was selected for this comparison of sugars because of superior growth of these segments on both sucrose and fructose at this concentration. Based on internodal extension, we find minimal growth response to galactose, mannose, xylose, lactose, and arabinose; intermediate growth on ribose, maltose, and glucose; and maximal response on sucrose and fructose. No significant difference is seen in linear growth of segments on fructose and sucrose at 0·1 M concentration. Fig. 2 illustrates the growth response of internodes in $P-1^{n-i}$ segments cultured on 0·1 M fructose. In another experiment, we found that *d*-sorbitol, myo-inositol, and *d*-mannitol (also 0·1 M) also induced an intermediate level of growth. Dry weight results for maltose, glucose, sucrose, and fructose indicate that increase in dry weight of the segments is rather substantial in comparison with segments cultured on other sugars.

In a comparison of growth responses of segments on different concentrations of fructose as opposed to sucrose (same *p*H and buffer), we again found no significant difference in growth response at 0·1 M concentration; but at 0·25 M, we clearly found superior growth with fructose (0·69 ± 0·05 cm/segment for fructose, 0·55 ± 0·06 cm/segment for sucrose). The same held true at 0·5 M concentration (fructose = 0·36 ± 0·07 cm/segment, sucrose = 0·14 ± 0·03 cm/segment). That fructose serves as such an excellent carbon source might be explained by its rapid exchange across membranes in excised segments[2] or its ready conversion to sucrose, one of the primary sugars that serves as a precursor in synthesis of polysaccharides[3].

Type Species of Foraminiferal Genera

IN the course of economic palæontological research we have found it necessary to consult some early nineteenth-century collections of Foraminifera, giving particular attention to those specimens which are the types of type-species of genera. We have examined original material in the A. d'Orbigny, Terquem, Berthelin, Michelin and Munier-Chalmas collections in Paris and, contrary to popular belief, have found that many of the original syntypic specimens are still extant in the authors' collections. The state of preservation as fossils and the state of curation as museum specimens of almost all the material found and listed here is such as to warrant their retention, with due selection of typical specimens, as the authentic types of the nominal species and, consequently, of the genera based on them.

In a number of cases the critical re-examination of the species and the selection and isolation of lectotypes has already been done by A. R. Loeblich and H. Tappan, some of whose selections have already been validated by publication[1,2], and the remainder of which we presume are about to be so validated.

We are now in a position to state that in addition to those specimens isolated and selected by Loeblich and Tappan for the genera which they examined, specimens of the following species have been selected by us as types and are now clearly so marked on the original mountings. We propose, in conjunction with other workers, to validate these selections, in strict accordance with the International Code of Zoological Nomenclature, by publication. In the interim we emphasize that, for the taxa listed here, with the three exceptions noted, no neotypes are required. In these lists, the genera for which the species are type are given in parentheses.

(1) Species published by d'Orbigny in 1826[4] (*Tableau Méthodique de la Classe des Céphalopodes*):

Lectotypes selected by us: *Alveolina quoii* (*Alveolinella*), *Amphistegina quoii* (*Amphistegina*), *Bulimina marginata* (*Bulimina*), *Clavulina communis* (*Martinottiella*), *Dendritina arbuscula* (*Dendritina*), *Lingulina carinata* (*Lingulina*), *Marginulina raphanus* (*Marginulina*), *Planorbulina mediterranensis* (*Planorbulina*). *Quinqueloculina secans* (*Massilina*), *Rotalia dubia* (*Pegidia*) (specimen isolated by Heron-Allen), *Rotalia italica* (*Turbinulina*).

Neotypes have been selected from ideotypic material for: *Truncatulina variabilis* (*Cibicidella*), *Valvulina triangularis* (*Valvulina*).

(2) Species published by d'Orbigny in 1839 (in work on Cuba[5], Canary Islands[6] and Central America[7]):

Lectotypes selected by us: *Biloculina sphaera* (*Pyrgoella*), *Nodosaria quadrilatera* (*Orthocerina*), *Orbiculina compressa* (*Cyclorbiculina*), *Peneroplis proteus* (*Puteolina*), *Rosalina squammosa* (*Cymbaloporetta*).

(Neotype selected from ideotypic material: *Glandulina laevigata* (*Glandulina*.))

(3) Species published by d'Orbigny in 1840[8] (*Belemnitella mucronata* zone Chalk of Paris Basin).

Lectotypes selected by us, in direct consultation with M. Pierre Marie: *Bulimina brevis* (*Eggerellina*), *Cristellaria recta* (*Enantiovaginulina*), *Gaudryina rugosa* (*Gaudryina*), *Globigerina elevata* (*Hagenowella*, designated by P. Marie), *Rosalina lorneiana* (*Pseudovalvulineria*), *Valvulina gibbosa* (*Hagenowella*, designated by J. A. Cushman).

(4) Species published by d'Orbigny in 1846[9] (in work on the Tertiary of the Vienna Basin).

Lectotypes selected by us: *Bulimina pupoides* (*Protoglobobulimina*), *Frondicularia annularis* (*Annulofrondicularia*), *Uvigerina aculeata* (*Euuvigerina*).

(5) We have also been able to select lectotypes for the following: *Annulina metensis* Terquem, 1862 (*Annulina*), *Involutina polymorpha* Terquem, 1874 (*Silicina*), *Rosalina lateralis* Terquem, 1878 (*Poroeponides*), *Triloculina laevigata* Terquem, 1878 (*Miliolina* Williamson), *Frondicularia paradoxa* Berthelin, 1879 (*Berthelinella*), *Pleurostomella barroisi* Berthelin, 1880 (*Pleurostomellina*), *Rhabdogonium liasinum* Berthelin, 1879 (*Tristix*), *Spirillina trochoides* Berthelin, 1879 (*Conicospirillina*), *Orbitolites pratti* Michelin, 1846 (*Orthophragmina*), *Cyclopsina steinmanni* Munier-Chalmas, 1887 (*Cyclopsinella*).

A lectotype of *Frondicularia bicostata* d'Orbigny, 1850 (*Ichthyolaria*) has been selected by us from Terquem collection material, as it is virtually certain that this was Terquem's type of the species, the name of which must, however, be credited to d'Orbigny as the name was first validly published in his *Prodrome*[10] (see also Macfadyen[3]).

Syntypes of *Gyroidina orbicularis* (d'Orbigny, 1826) Parker, Jones and Brady, 1865, exist in Paris, but their nature is such that a lectotype for this species, the type species of *Gyroidina*, has had to be selected from the Parker, Jones and Brady collection in London (British Museum (Natural History)).

(6) The following lectotypes, selected by Loeblich and Tappan, are present in the Paris collections examined by us: d'Orbigny, 1826[4]: *Adelosina laevigata* (*Adelosina*), *Clavulina angularis* (*Clavulina*), *Nonionina sphaeroides* (*Pullenia*), *Planorbulina vermiculata* (*Cyclocibicides*), *Rimulina glabra* (*Rimulina*)[1], *Rotalia turbo* (*Trochulina*), *Sphaeroidina bulloides* (*Sphaeroidina*).

d'Orbigny, 1839[5-7]: *Asterigerina carinata* (*Asterigerina*), *Conulina conica* (*Conulina*), *Cruciloculina triangularis* (*Cruciloculina*)[2], *Faujasina carinata* (*Faujasina*), *Nonionina browni* (*Cushmanella*), *Oolina laevigata* (*Oolina*), *Polystomella poeyana* (*Elphidiononion*), *Sagrina pulchella* (*Sagrina*), *Webbina rugosa* (*Webbina*)[1].

d'Orbigny, 1840[8]: *Flabellina rugosa* (*Neoflabellina*), *Pyrulina acuminata* (*Pyrulinoides*), *Sagrina rugosa* (*Heterostomella*), *Verneuilina tricarinata* (*Verneuilina*).

d'Orbigny, 1846[9]: *Cyclolina cretacea* (*Cyclolina*), *Hauerina compressa* (*Hauerina*)[1], *Lingulina rotundata* (*Ellipsonodosaria*), *Spirolina agglutinans* (*Ammobaculites*).

Terquem, 1866: *Marginulina colliezi* (*Pseudocitharina*).

We thank M. Pierre Marie and Mme. Y. Le Calvez of the Bureau de Recherches Géologiques et Minières for facilities, help and encouragement in locating and working on type material, MM. Lehmann, Fischer and Sornay of the Muséum National de l'Histoire Naturelle, M. Beauvais and Prof. J. Jung of the Laboratoire de Géologie, Faculté des Sciences à la Sorbonne, and M. l'Abbé de Lapparent of the Institut Catholique for their help in enabling us to examine the collections in their care. All the foregoing specimens (with the single exception of *Cyclopsina steinmanni*, which is in the Sorbonne) are deposited in the care of the Muséum Nationale de l'Histoire Naturelle, Paris.

We thank the Chairman and Directors of the British Petroleum Co., Ltd., for permission to publish this

communication and also acknowledge the assistance of colleagues on the staff of BP associated companies in France.

MICROBIOLOGY

Bacteriolytic Principles of *Myxococcus fulvus*

MEMBERS of the Myxococcaceae are ideal for the examination of some fundamental phenomena unique in the world of bacteria: (1) the mechanism of the gliding movement of the vegetative forms on solid media[1]; (2) the morphogenesis of the fruiting body, following the gathering in of the swarming rods with the simultaneous transformation into microcysts[2]; (3) the production of lytic principles capable of attacking different bacterial and fungal cells on which the formation of fruiting bodies readily takes place[3,4].

This communication deals with some observations made on *Myxococcus fulvus* which may throw some light on the mode of action of the lysis of bacteria by myxobacteria.

Singh, Oetker, Kühlwein *et al.*[3,5,6] have described the lytic activities of myxobacteria. Most of their work was concerned with the breakdown of eubacteria. Nolte[4] also compared the lytic activity of several myxobacteria, for example, *M. fulvus*, *M. virescens*, *M. stipitatus* and *Podangium erectum*, on yeast and mycelial fungi of various orders, as well as algæ and myxomycetes. In most cases growth and formation of fruiting bodies would occur on bacteria and lower fungi, while higher fungi and other thallophyta seemed to be resistant to the attack of the myxobacteria, presumably due to the presence of chitinic substances in the structure of the cell wall[6].

One might conceive three possibilities for the mode of action of myxobacteria on living bacteria:

(1) The lytic principle of myxobacteria is capable of both the inactivation of the organism as well as its lysis by a mechanism similar to that of lysozyme[7].

(2) Living bacteria are susceptible to the action of myxobacteria only if they are primarily attacked by an antibiotic substance or some similar principle, the actual lysis being carried out by some unspecific proteolytic enzyme(s) which would be responsible for the complete dissolution of the bacterial cell contents and/or cell wall.

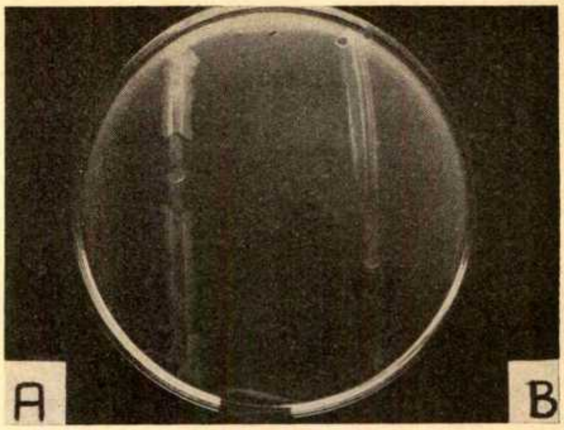

Fig. 1. *Myxococcus fulvus* on *E. coli* (nutrient agar). *A*, Living *E. coli* ; *B*, dead cells

(3) Lysis of bacteria can occur only in the case that as a result of some sort of a trigger action of the myxobacteria on the substrate organism (for example, the deprivation of some vital nutrilite) death would occur followed by rapid autolysis.

Working with a strain of *M. fulvus* isolated from local garden soil the following technique was utilized. The organism was grown on 0·3 per cent casein agar which was prepared by stirring the casein at *p*H 9·0 (sodium hydroxide) until complete dissolution of the protein. The solution was then neutralized before the addition of agar–agar and autoclaved. The inoculum consisted of an agar disk (5 mm diameter) taken from the peripheral, non-fruiting part of a colony. The following observations were made:

(1) There is virtually no difference between the lysis of Gram-positive and Gram-negative bacteria. This can be best demonstrated by comparing the lysis and formation of fruiting bodies on bacteria applied in a thick paste on water agar (2 per cent agar–agar in tap water). Within 3–5 days lysis and fruiting would occur upon Gram-negative bacteria (*Escherichia coli*, *Serratia marcescens*), on non-sporing Gram-positive bacteria (*Lactobacillus arabinosus*, *Micrococcus* sp.); though some difference in the rate of lysis and fruiting can be observed with bacilli (*B. subtilis*, *B. mycoides*) probably due to the formation of endospores as already pointed out by Oetker[5].

(2) There are practically no differences in the lysis or formation of fruiting bodies on living or autoclaved bacteria, when applied on nutrient-free water agar.

(3) When living cells are streaked on nutrient agar, *E. coli* would be lysed by *M. fulvus*, but not to the same extent as autoclaved cells applied similarly (Fig. 1).

(4) Repeating the foregoing experiment on 0·3 per cent casein agar the following picture was obtained. Around every disk of inoculation a distinct halo of proteolysis was formed. While this would correspond to the extent of lysis of autoclaved cells, the zone of proteolysis would be much larger than the lysis of living *E. coli* (Fig. 2).

(5) Although antibiotic activity has been attributed to some myxococci such as *M. virescens* against Gram-positive bacteria[8] and against virus[9], no water-soluble antibiotic could be demonstrated from *M. fulvus*, using *E. coli* as test organism.

From the foregoing observations some theory on the mode of action of *M. fulvus* was attempted. The lytic principle of the *Myxococcus* is most probably

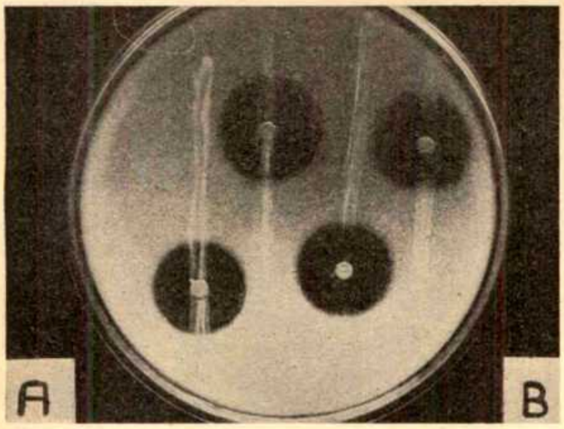

Fig. 2. *M. fulvus* on *E. coli* (0·3 per cent casein-agar). *A*, Living *E. coli*; *B*, dead cells

unlike that of lysozyme in not distinguishing appreciably between Gram-positive and Gram-negative bacteria. The lysis of actively growing cells occurs at a much lower rate than that of dead cells, probably due to metabolic products produced by the former which inhibit the growth of the myxobacterium. Whereas growing cells of *E. coli* are killed by the *Myxococcus* on contact, and not by a diffusable substance, the dead cells are lysed by the proteolytic enzyme(s) practically to the same extent as the breakdown of another protein substrate.

The lysis of living cells seems, therefore, to be the result of the common effort of two principles: a 'killer' and a proteolytic enzyme. So far, practically nothing is known about the nature of the 'killer' although its non-specificity towards its substrate organisms is one of its striking features.

I thank Prof. M. Aschner for his interest in this work and Mr. S. Handelsman for the photographs.

Binding of Chlortetracycline on the Sporulating Cells of Bacilli and the Atypical Development of Spores

THE affinity of tetracycline antibiotics for divalent metal cations[1-2] led to the hypothesis that the biological effect of these antibiotics is dependent on the presence of these cations and is brought about by complexing with macromolecules through metal ions. The formation of metal bridges was proved, for example, in binding of tetracyclines on serum albumin or deoxyribonucleic acid[3]. Metal-mediated binding of tetracyclines to macromolecules or cells assumes the presence of specific receptors, binding the metal cation.

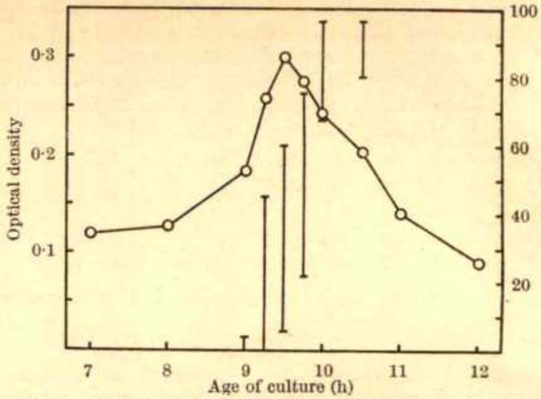

Fig. 1. Binding of chlortetracycline on the sporulating cells of *Bacillus cereus*. Vertical abscissæ stand for the percentage of spores formed during contact with CTC

Sporogenesis of bacilli is connected with the intensive incorporation of calcium into the cells and, therefore, the primary mobilization of binding sites for calcium inside or on the cell surface might be expected. To test the possibility of interference of tetracycline antibiotics with sporogenesis the cells of *B. cereus* (N.C.I.B. 8122) grown in bactopeptone-glucose-salts liquid medium were kept in contact with chlortetracycline for 60-min intervals, chlortetracycline (CTC) being added in the different stages of stationary phase. Concentration of calcium in the medium was 1×10^{-4} M and chlortetracycline ('Aureomycin' Lederle) was added into individual flasks with culture in the concentration 5 µg/ml. of medium. The binding of chlortetracycline on the cell was estimated by measuring the fluorescence of the cells in ultra-violet light. The values (Fig. 1) express the optical density of fluorescent filters with cells measured by a transparometer[4] and the individual values, with regard to the time axis, stand for the moment of addition of chlortetracycline. Simultaneously the percentage of pre-spores and spores was estimated in the moment of addition of CTC and after 60 min contact. Spore formation is expressed by vertical abscissæ, the bottom values standing for the

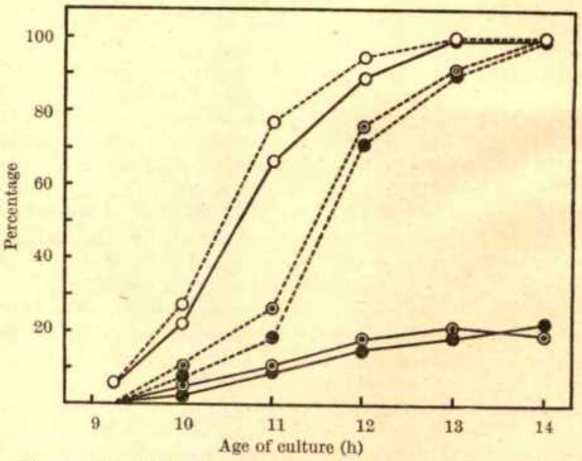

Fig. 2. Sporulation, incorporation of calcium-45 and synthesis of dipicolinic acid in control (dotted lines) and CTC-treated (full lines) culture (values expressed in percentage, final values of control culture being taken as 100 per cent). ○, Sporulation; ●, DPA synthesis; ⊙, incorporation of calcium-45

percentage of spores at the moment of adding CTC, the upper ones for that at the moment of sampling.

Although the method of measuring the fluorescence is only semi-quantitative it shows the relative changes in the amount of CTC bound on cells. The fluorescence tests show that during the period of spore formation the ability of cells to bind chlortetracycline is much increased. Chlortetracycline can be washed out by different washing procedures using *tris* buffer, 0·001 M citric acid, etc. Similar results were obtained with *Bacillus megaterium*.

During my investigations of binding of calcium-45 on the cells in the stage of pre-spores I found that in this period the adsorption of calcium on the cell surface is markedly increased. Also this calcium can be easily washed away and the removal of this 'labile' calcium by different solutions is practically the same as that of chlortetracycline bound during sporulation. It may be assumed that this 'labile' calcium mediates the binding of CTC on the cell surface.

The penetration of calcium inside the cells is accompanied by the synthesis of dipicolinic (pyridin-dicarboxylic) acid (DPA). I therefore followed the influence of CTC on the calcium-45/1 μc./ml./uptake by sporulating cells and the formation of dipicolinic acid. DPA was estimated by the method of Janssen, Lund and Anderson[5]. Chlortetracycline was added (3 μg/ml.) into experimental flasks after formation of about 5 per cent of pre-spores. The results are given in Fig. 2. Chlortetracycline blocks the penetration of calcium inside the cells and the synthesis of dipicolinic acid.

The blockade of uptake of calcium by sporangia and of the synthesis of dipicolinic acid leads to the changes in morphology of spores. The spores formed are less refractive and usually more spherical. Their appearance resembles the so-called 'defective spores' formed in the excess of cystine or its breakdown product, hydrogen sulphide[6]. The post-sporulation autolysis of sporangia treated with chlortetracycline is disturbed, as it was in the case of 'cystine inhibition'.

It is possible that chlortetracycline inhibits some of the processes leading to the synthesis of DPA. On the basis of highly increased binding of chlortetracycline on sporulating cells it may be assumed, however, that the inhibition of calcium uptake and DPA synthesis is more likely brought about by blocking the cell surface. The molecule of tetracycline attached to calcium bound on the cell surface forms a complex which may not penetrate into the cell and/or is unable to induce DPA synthesis.

Effect of Multi-site Mutation to Colicine Resistance on Recombination and Segregation in *Escherichia coli*

SOME phage-resistant mutants of *Escherichia coli* are resistant to some colicines, and vice versa[1,2]. Among mutants selected for resistance to colicine *B* four different classes result from mutation near the *try* (tryptophan-requirement) locus: (1) resistant to colicines *B* and *I*; (2) resistant to colicines *B*, *I* and *V* and to phage *T*1; (3) like (2), but tryptophan-exacting, responding also to indole; (4) like (2), but tryptophan-exacting, not responding to indole. The phenotypes of these four classes and genetic analysis by transduction using phage *P*1 and several tryptophan-exacting mutants[3] of *E. coli K*12 suggest that mutants of classes (2), (3) and (4) arise by multi-site mutations (presumably deletions) of variable extent (Fig. 1), in class (3) involving the *try* 2 locus, with resulting inability to convert indole glycerophosphate to indole, and in class (4) involving both *try* 2 and *try* 1, with resulting inability to convert indole glycerophosphate or indole to tryptophan. Yanofsky and Lennox[3] similarly concluded that tryptophan-exacting phage-*T*1-resistant mutants, which include classes (3) and (4), arose by deletion.

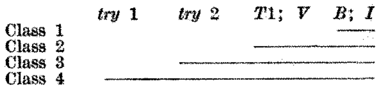

Fig. 1

In crosses, by conjugation or transduction, with phage *P*1, between strains one of which carried a 'deletion' mutation of types (2), (3) or (4), minute colonies containing persistent heterozygotes, at least for the *try* region, were observed; delayed recombination led to production of stable *try*$^{+}$ segregants. Clones heterozygous for several loci not closely linked to *try*, including *gal*, *met*, *azi* and *str*, segregated the parental and various recombinant types. The following results indicate that these effects result from the deletion, rather than merely from mutation involving the *try* region.

In a control $F+$ by $F-$ cross an $F+$ streptomycin-sensitive strain requiring anthranilic acid (or indole or tryptophan) through point mutation in *try*4 was crossed with a streptomycin-resistant F-strain tryptophan-exacting through point mutation in *try*1; on a casein–hydrolysate–streptomycin medium *try*1^{+} *try*4^{+} recombinant colonies of normal size developed with a frequency of about 2×10^{-5} per $F+$ bacterium. In one experimental cross the $F-$ parent was likewise tryptophan-requiring, but because it carried deletion (4) which includes *try*1. The number of large colonies obtained was less than in the control cross and there also appeared numerous small colonies, each consisting largely of *try*4 *str-r* cells fed by some tryptophan precursor, probably anthranilic acid, excreted in large amount by the deletion-4 parent. After several days faster growing sectors of *try*1^{+} *try*4^{+} recombinants developed in many of the small colonies, which must therefore have contained clones heterozygous for *try*4. Enumeration of *try*$^{+}$ bacteria by re-spreading at intervals after plating showed an abnormal delay, of variable duration, before such recombinants began to multiply. In another experimental cross the $F+$ parent was *try*4^{-}, as in the control cross, but also carried deletion (2), conferring resistance to colicine *B*, *I* and *V* and phage *T*1; the $F-$ parent was *try*1^{-}, as in the control cross. The number of colonies obtained on casein–hydrolysate–streptomycin medium was much less than in the control cross. Some additional colonies, of variable size but mostly small, appeared on prolonged incubation. These correspond to the fast-growing *try*$^{+}$ sectors developing in the small, mainly *try*4^{-}, colonies seen in the other experimental cross; the expected $try4^-$ component could be recognized on replication to medium supplemented with anthranilic acid. In this cross also re-spreading experiments showed that the number of bacteria able to produce try^+ colonies did not begin to increase until after a variable abnormal delay. Thus in $F+$ by $F-$ crosses the presence of a deletion mutation in either parent causes: (1) delay in the production of try^+ recombinants, a class which requires crossing-over near the deletion; (2) the development of small colonies apparently through multiplication of cells heterozygous for the *try* region, since they produce both $try4^-$ and $try4^+$ progeny.

The presence of a deletion in either parent also modified the outcome of *Hfr* to $F-$ crosses, as follows. In crosses of *HfrH* (met^-, transmitting *thr* and *leu* early and *try* later[4]) with F-strains marked by thr^-, leu^- and $try4^-$, the presence or absence of a deletion in the *Hfr* parent did not affect the yield of recombinants selected for thr^+ leu^+ from the *Hfr* parent. But when $try4^+$ was also selected for, the presence of deletion (2) in the *Hfr* parent greatly reduced the number of colonies obtained, which were of variable size. Testing of clones derived from 20 such colonies showed them to be heterogeneous, indicating delayed segregation at several loci, including *thr*, *leu* and *try*4. The presence of deletion (4) in the $F-$ parent also caused aberrations, though less apparent ones. Colonies selected on tryptophan-supplemented medium for possession of thr^+ and leu^+ from the *Hfr* parent and found by replication to contain some try^+ cells showed delayed segregation for try^+ and other characters derived from the *Hfr* parent. The number of recombinants was not reduced when thr^+, leu^+ and try^+ from the *Hfr* parent were selected for, but re-spreading experiments showed a delay of 4 h before they began to multiply, compared with two h for thr^+ leu^+ recombinants in the same cross and for thr^+ leu^+ try^+ recombinants in a control cross in which neither strain carried a deletion. When the *Hfr* parent was $try4-$ instead of try^+ and the $F-$ parent was tryptophan-exacting because of deletion (4) small colonies, made up in large part of $try4-$ recombinants, were obtained on a medium selective for thr^+ leu^+ try^+; only large colonies, of try^+ recombinants, were obtained in a control cross with an $F-$ parent carrying $try1^-$ instead of deletion (4). Thus in *Hfr* by $F-$ crosses a deletion in either parent, but especially in the donor, causes failure or delay in recombination and a variable persistence of heterozygosis for part of the chromosome, but only among those F-cells which receive the *try* region transmitted by the *Hfr*.

When the *try* or *his* regions were transduced by phage $P1$, a deletion in either donor or acceptor strain resulted in persistent heterozygosis among the *try* but not the *his* transductants, the effect being greater when the donor carried the deletion.

Thus on mating or transduction, the presence in either parent of a deletion causing resistance to certain colicines and phage $T1$ inhibits or delays recombination in the adjacent *try* region and causes a variable persistence of partial heterozygosity among the progeny of bacteria which receive the *try* region of the donor. The effect of mutation at other loci controlling sensitivity to colicines and phages, and the relation of the present observations to the 'Het' factor inferred by Lederberg[5,6] from experiments with a mutant resistant to phage $T1$, are being investigated. Examination of persistent heterozygotes has now shown that sensitivity to colicine B, V, I and K, like sensitivity to phage $T1$, $T5$ and $T6$, is dominant to resistance.

ENTOMOLOGY

Neurosecretion and the Transport of Secretory Material from the Corpora Cardiaca in Aphids

THE development of differential staining techniques for neurosecretory material in animals made it theoretically possible to trace secretions from their source to their point of release or utilization. In most cases, however, insufficient secretory material is present to enable more than a very incomplete picture to be obtained. In adult aphids which are several days old large amounts of material tend to accumulate in the axons of some neurosecretory cells and it has been possible to follow its course.

The following account is based on studies of serial sections of several species of aphids, principally *Aphis fabae* Scop. and *Drepanosiphum platanoides*. The most effective stain was found to be Gomori's paraldehyde fuchsin, and this stains the secretion of only a few of the neurosecretory cells present in the brain and other ganglia.

Two large neurosecretory cells are situated near the mid-line on the dorso-anterior surface of the protocerebrum. Secretory granules can be traced from the cell bodies along their axons, each of which passes through the brain and then branches so that

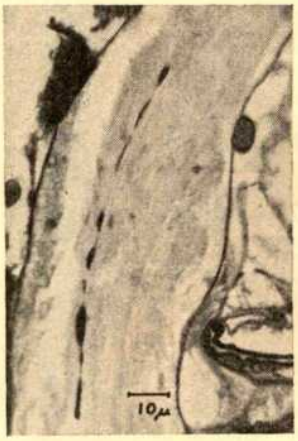

Fig. 1. Photomicrograph of a longitudinal section of the sub-œsophageal ganglion of an old virginopara of *A. fabae* Scop. showing extensive deposits of neurosecretory material along one of the axons which pass from the brain neurosecretory cells to the hindgut. (Stained with Gomori's paraldehyde fuchsin after permanganate oxidation)

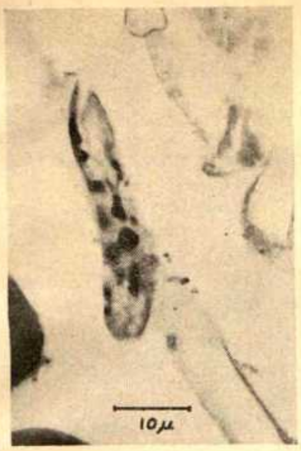

Fig. 2. Photomicrograph of the lateral nerve from the corpus cardiacum of a virginopara of *D. platanoides* as it passes over a trachea in the prothorax. The dark staining inclusions are secretory material from the corpora cardiaca. (Stained with Gomori's paraldehyde fuchsin after permanganate oxidation)

one branch of each axon passes along the nervus corporis cardiacus while the other goes into the circum-œsophageal connective and continues along the ventral nerve cord. Similar cells with axons containing neurosecretory granules passing along the ventral nerve cord have recently been described in larvæ of a mosquito *Corethra*[1].

The branches of the axons which pass along the nervi corporis cardiaci appear to terminate in the corpora cardiaca where copious amounts of fuchsinophilic material sometimes accumulate. This material differs in character from that found in the axons of the neurosecretory cells in that it is not granular and it occurs in relatively large drops. In aphids in which large amounts of this secretion are present, it can clearly be followed from the corpora cardiaca into two pairs of nerves, a lateral and a medial pair. In cross-section these nerves can each be seen to consist of a single giant axon which appears to function as a duct transporting secretion from the corpora cardiaca. The nerves are not of uniform thickness and in *Drepanosiphum* individual axons vary in width from 3μ to 10μ. They have no nuclei except where they branch.

The medial pair of nerves pass over the centrally placed fused corpus allatum and join together to form a single nerve which continues along the ventral surface of the aorta; attached to this nerve are the pericardial cells. The lateral pair of nerves, which are larger and contain more secretory material, follow tracheæ to the vicinity of the prothoracic spiracles and then pass downward and backward into the abdomen. Branches have been traced to various muscles in the prothorax and near the metathoracic and first abdominal spiracles; another branch from each nerve passes upward and rejoins the medial nerve in the abdomen. Although the lateral nerves pass close to the ecdysial glands, which are situated near the prothoracic spiracles, they do not appear to have any direct tissue connexion with them.

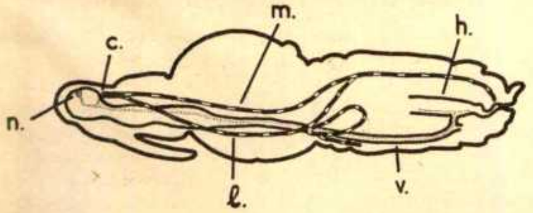

Fig. 3. Pathways of secretory material along nerve axons from the brain neurosecretory cells and corpora cardiaca in *Drepanosiphum platanoides*. *n*, Neurosecretory cell; *c*, corpus cardiacum; *m* and *l*, medial and lateral nerves from the corpus cardiacum; *v*, ventral nerve cord; *h*, hindgut

The neurosecretory axons which pass along the ventral nerve cord were also traced. After continuing along it for some distance into the abdomen they pass into two nerves which go to the ventral surface of the hindgut. Adhering to the hindgut each of the axons then divides again: one branch of each going forward, the other backward, the two axons running parallel to one another and extending over about one-third of the hindgut. The secretory material is distributed along the axons on the hindgut in a series of bead-like swellings. In some aphids vacuoles have been found in the swellings.

Secretions from the corpora cardiaca in insects have been shown to influence a number of different functions. These include moulting[2], water metabolism[3], rate of heart-beat[4], contractions of parts of the intestine[5] and oviducts[6], physiological colour change[2] and protein synthesis[7]. In some of these the corpus cardiacum extract is known not to act directly but to stimulate an intermediate system. Rate of heart-beat and hindgut contractions have recently been shown to be influenced by an indolalkylamine which is released by pericardial cells and cells of the colon when they are activated by corpus cardiacum extracts[4,5]. In aphids both these tissues appear to receive secretory material which originates from the same neurosecretory cells in the brain and which is transported to them along nerve axons.

Secretions from the corpora cardiaca are generally believed to be released directly into the blood[8] although direct evidence of this is lacking. The fact that in aphids large amounts of secretory material appear to leave the corpora cardiaca along the lateral and medial nerves suggests that this may be the main method of release and that the material does not normally enter the blood at all but is transported directly to the tissues it influences. The presence in aphids and *Corethra* larvæ of neurosecretory material extending right along the ventral nerve cord further indicates that the neuroendocrine system of insects may be more of a closed system than has previously been thought.

This work was done during my tenure of a Nuffield Dominion travelling fellowship. I thank Prof. G. C. Varley for allowing me to work in his department.

GENETICS

A Gene synthesizing Deoxyribonuclease in the Polyhedral Pre-viral Genome

IT has been reported[1] that in the chromosome of larvæ of *Bombyx mori* there is a pre-viral genome containing a gene synthesizing protease. We have now shown that the genome contains a gene controlling the synthesis of an alkaline deoxyribonuclease.

Our previous work[2] showed that the pupa of *B. mori* possesses no alkaline deoxyribonuclease. About 700 young pupæ of P_{21} strain were each injected with 0·02 ml. of polyhedral solution (0·1 mg/ml.), and polyhedra were collected from diseased individuals[3]. Virus particles were then isolated from the polyhedral crystals according to the method previously described[4]. To measure the deoxyribonuclease action of polyhedral virus, 1 ml. of enzyme solution was mixed with 1 ml. of deoxyribonucleic acid (from cattle spleen) solution (0·5 mg/ml.), 1 ml. of 0·2 M sodium carbonate + orthoboric acid + potassium chloride buffer and 0·3 ml. of 0·01 M magnesium sulphate solution. The enzyme solution was prepared by homogenizing thoroughly 5 mg of viral particles with 1 ml. of 0·02 N sodium carbonate. The *p*H of reaction mixtures was appropriately regulated by adding 0·2 N hydrochloric acid or sodium hydroxide. In the control, 1 ml. of water was added instead of the substrate. The reaction temperature was 40° C and the time 3 h. After the reaction, the solutions were each mixed with 1 ml. of 1 M perchloric acid, centrifuged at 3,000 r.p.m. for 10 min and further filtered. The enzymatic activity was determined spectrophotometrically and expressed in increase of absorption (log T) at 260 mμ. Some of the results obtained are given in Table 1.

Table 1. DEOXYRIBONUCLEASE ACTION OF POLYHEDRAL VIRUS

*p*H of reaction mixture	7·0	8·0	8·8	9·6	10·5	11·1	11·8	12·6
Log T	0·017	0·043	0·152	0·291	0·382	0·432	0·446	0·410

It is thus obvious that the polyhedral virus forms a deoxyribonuclease which displays the maximum activity at about *p*H 12. As this virus is of a deoxyribonucleic acid nature and produced only in the nucleus, it can be concluded that in the virus a gene exists which synthesizes the alkaline deoxyribonuclease.

Our previous investigations[3,5] also indicated that the *B. mori* larva has an alkaline deoxyribonuclease and produces polyhedra containing a deoxyribonuclease of the same nature. The white cuticle of the P_{44} strain and the black cuticle of the P^S strain respectively were taken in the same way as before[1]. The two strains were then crossed and the cuticle was further taken from the descendants in the F_1- and F_2-generations. To estimate the deoxyribonuclease action of cuticle, 0·5 ml. of enzyme solution was mixed with 1 ml. of deoxyribonucleic acid solution (2 mg/ml.), 1 ml. of 0·4 M sodium carbonate–orthoboric acid–potassium chloride buffer of *p*H 9·6 and 0·3 ml. of 0·01 M magnesium sulphate. The enzyme solution was prepared by centrifuging the suspension obtained after grinding 50 mg of cuticle with 1 ml. of 0·5 M sodium chloride for 30 min at 37° C. The reaction temperature was 30° C and the time 30 min. The enzymatic activity was determined viscosimetrically and expressed in velocity constant, k, of monomolecular reaction. The results are given in Table 2.

TABLE 2. DEOXYRIBONUCLEASE ACTION OF LARVAL CUTICLE

Generation	P_{44}	PS	$P_{44} \times PS - F_1$	$P_{44} \times PS - F_2$	
Colour of cuticle	White	Black	Black	White	Black
$k \times 10^4$	65	128	133	56	111

It is thus evident that there is a correlation between the activity of nuclease and colour of the skin. As stated before[1], the colour of P_{44}- and P^S-cuticles is governed by the genes in the second chromosome in the larval cell and the black of P^S is the dominant. Accordingly, it may be concluded that the gene synthesizing the alkaline deoxyribonuclease is located in the chromosomes, possibly in the second chromosome.

It is supposed that the genome containing the genes synthesizing deoxyribonuclease and protease is highly resistant, can independently multiply and may cause the decomposition of the other chromosomal portion consisting of deoxyribonucleic acid and protein. As the metabolic processes in silkworm tissues proceed near the neutral reaction, it is surmised that the genes producing the alkaline enzymes might have been formed by a mutation in the past. The production of the polyhedral virus can thus be formulated as in the following scheme.

Cell containing normal chromosome
↓ mutation
Cell containing pre-viral genome
↓ induction
Cell containing viral particle

The induction is caused by the metabolites which appear as intermediates in the cyclic reaction established by us[6]. It is possible that the mutation also might have been caused by some of the metabolites such as nitrous acid, hydroxylamine and hydrogen peroxide, which can act as mutagens[7-9].

Immunogenetics of the Domestic Mink: Blood Group Factors A, B_1 and B_2

SEROLOGICAL differentiation of red blood cells, especially in such species as man, cattle and the chicken, is well known[1,2,5]. It has been established that red blood cells have antigenic properties on their surfaces; further, these antigenic properties are hereditary characters, their structures being determined by genes. Blood group investigations have proved helpful in elucidating the nature of the chain of events from gene to character, as well as of practical use in animal breeding[3,4,6]. So far as we are aware, nothing on blood groups in the domestic mink (*Mustela vison*) has been published.

Table 1. ANALYSIS OF ISO-IMMUNE AND HETERO-IMMUNE SERA AGAINST MINK RED CELLS

Species	No. injected	No. responding	Type antibody	Titre	No. of samples of red blood cells used for absorption of each serum	No. of specific reagents
Mink	76	15	Agglutinin	1 : 2–1 : 16	12–53	3 Anti-A 4 Anti-B_1 and B_2
erret	8	8	Agglutinin Hæmolysin	1 : 32 1 : 8	24	2 Anti-B_1 —
bbit	12	12	Agglutinin Hæmolysin	1 : 1,000–1 : 4,000 1 : 500–1 : 2,000	15–18	1 Anti-A 1 Anti-B_1 —
Chicken	12	12	Agglutinin	1 : 16–1 : 64	12	1 Anti-A 1 Anti-B_1
Guinea pig	14	14	Agglutinin Hæmolysin	1 256 1 . 256	15	— —

The 612 mink used in this investigation were of various colour phases from the herd of the Fur Animal Research Laboratory, University of Wisconsin. 8–15 ml. of blood were drawn from each animal by cardiac puncture into an isotonic solution of sodium citrate (2·3 per cent) and sodium chloride (0·4 per cent). Blood samples were kept at 4° C for use within 10 days, or stored at $-20°$ C for later use. Additional details regarding the techniques used will e described elsewhere.

Neither normal agglutinins nor hæmolysins were found in the sera of the initial group of 53 animals ested. An agglutinin was manifest in a single individual among 121 examined six months subsequent to the first test: from the results of comparing this serum with reagents prepared from isoimmune sera, it appears that this one mink has antibodies against a mink blood group tentatively designated B_2. Sera of all mink lacking the antigen B_2 were checked, but in no case were antibodies against this blood type found.

Agglutinins or hæmolysins for mink red blood cells, or both, were found in the sera of the chicken, marten, rabbit, guinea pig, cattle and man: of the seven species tested, only the ferret failed to show cross-reacting antibodies with the mink. Consequently, fresh sera from rabbits and most guinea pigs cannot be used as complement. The sera of two guinea pigs of 18 used showed agglutinins of very low titre (1 : 2), and could be used as complement in dilutions of 1 : 14; however, results from such tests may be questionable.

122 individuals were immunized against mink red cells to get iso- and hetero-immune sera: 76 mink, 12 rabbits, 12 chickens, 14 guinea pigs and 8 ferrets. The immune sera were prepared as follows: 2–4 ml. of a mixture of equal parts of mink erythrocytes (washed three times) and saline solution (0·85 per cent) were injected 5–6 times into each recipient, the animals bled 7–10 days following the last injection, and the sera stored at $-20°$ C. Paired recipients of each species used were given red cells from a single donor. The results are shown in Table 1.

Of the 76 mink injected, 30 were young (six months); only one of the young group responded (weakly), while among the adults 14 produced antibodies. The red blood cells used for absorption were taken from mink chosen at random. At least seven different reagents were detected from the 14 immune sera, leading to the recognition of seven blood factors. Since the mink is so small, only three reagents were obtained in quantities sufficient for extensive tests; four reagents from single individuals were expended for absorptions.

Each hetero-immune serum reacted with the blood cells of all mink tested as shown in Table 1. By absorption, it was possible to distinguish reagents from the hetero-immune sera which seems identical with certain reagents obtained from the iso-immune sera. All reagents functioned as agglutinins; consequently, saline agglutination tests were utilized in additional studies. Reagents used in these investigations have given consistent and clear-cut (+ + +, + + + +) results.

The symbols assigned to the three blood factors are A, B_1 and B_2: their frequencies in this population were, respectively, 64, 55 and 77 per cent. Five phenogroups, A_1, B_1B_2, AB_1B_2, AB_2 and B_2, were found in the sample of 612 mink tested, and each individual was identified as belonging to one or another of these groups. Pedigree analysis of this population suggests that the three blood factors are members of a single system, and are determined by alleles or closely linked genes. Investigations of inheritance will be presented in a report to follow.

AGRICULTURE

Low-Cost Weighable Lysimeters

Glover and Forsgate[1] have recently proposed a method for weighing a soil-filled lysimeter by noting pressure variations in a water-filled bag on which the lysimeter tank rests. Lysimeters working on this principle have been operating here during the past year.

Field results obtained with four such replicate instruments are shown in Fig. 1. Soil moisture deficit estimated daily by a method based on that of Penman is included for comparison, and the response of the lysimeters to rainfall is clearly seen.

Glover and Forsgate mention the possibility of errors arising from ambient temperature fluctuations; but at Wellesbourne it has been found that, with the lysimeters buried so that their soil surfaces were at

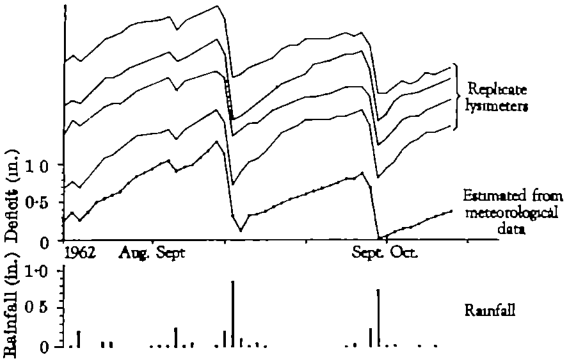

Fig. 1. Records from four replicate grassed pressure-weighing lysimeters in the open at Wellesbourne during 1962, compared with soil moisture deficit estimated from meteorological records and rainfall collected in a standard gauge. For clarity, the lysimeter records have been displaced vertically, but all the data shown are on the same scale

ground-level, natural air and soil temperature variations had a negligible effect on the manometer readings. It has not been found necessary to keep the manometer itself under thermostatic conditions as shown in the illustration accompanying the communication of these authors.

As a routine check on the correct functioning of each lysimeter, at the time when the daily reading is made, a special weight equivalent to 1/10 in. of water spread over the exposed lysimeter surface may be added temporarily. With our instruments this results in a vertical manometer deflexion of about 2/10 in.

A full description of these lysimeters is in the press[2].

The use of lysimeters for direct measurement of water use by plants growing in different soils under varying conditions of soil moisture stress has been limited in the past by the high cost of the necessarily large number of weighable instruments. The lost cost and absence of need for precision engineering which are features of the pressure-weighing equipment referred to here, will enable more detailed investigations of plant water use to be carried out than hitherto.

I wish to acknowledge the help of Miss Christine Down in building and maintaining these lysimeters, and in recording the results.

SOIL SCIENCE

Effect of Freezing of Soil on Denitrification

A MAJOR difficulty in investigations of biological processes in soils is the preservation of the biological activity from the time of collection of the soil sample in the field until commencement of the laboratory investigation. Freezing of soil samples could feasibly be the means of preserving this biological activity since microbial growth ceases and enzymatic actions are retarded at low temperatures. Gasser[1] has suggested that the nitrifying activity in freshly sampled soil can be retained in this way. Since then, other workers have shown that when soils frozen at temperatures of −78° C and −196° C are thawed and incubated, increased nitrogen mineralization and aerobic respiration result[2,3].

Table 1. COMPARISON OF DENITRIFICATION WITH DIFFERENT FREEZING AND INCUBATION PRE-TREATMENTS

Treatment*		µg nitrogen/g soil Time (h) 36	 72	 108	 144

* Nitrate nitrogen was added to give a level of 177 µg nitrogen/g soil to all treatments.

Present investigations of the denitrifying potential of soils utilized for wheat growing require freshly sampled soil from areas distant from our laboratories. The efficacy of various freezing treatments on the preservation of denitrifying activity in soil was therefore examined.

A black earth top soil (0–3 in., *p*H 6·3) was sampled from a wheat field adjacent to the laboratories. It contained 2·895 per cent organic carbon, 45·0 per cent moisture, and 2 p.p.m. nitrate nitrogen. The denitrifying activity was determined immediately after sampling, and the remainder of the sample was divided into five portions, which were placed in covered, but not airtight, containers; each of th portions was subjected to one of the following treatments.

(1) Frozen with acetone–solid carbon dioxide mixture and maintained in the range −78° C to −30° C.

(2) Frozen in a deep freeze cabinet and maintaine in the range −5° C to 0° C.

(3) Frozen in a refrigerator and maintained in th range 0° C to 2° C.

(4) Placed in an incubator and maintained in th range 30° C to 31° C.

(5) Air dried and maintained in the range 15° C t 19° C.

The stated temperatures were maintained from th date of sampling, August 30, 1960, until Septembe 27, 1960. Treatments (1)–(4) showed only a slight loss of water (1–3 per cent) while the content of wate in the air-dried sample fell to 11·4 per cent. After 28 days, duplicate 20-g samples of soil aggregates (2 3 mm) from each treatment were brought to saturation, and the denitrifying activity was determined by the manometric technique[4], using the production of nitrogenous gases from potassium nitrate substrate added to the anaerobic soil as a measure of this activity. Gas evolved from soil during 144 h incubation at 30° C has been calculated as micrograms of nitrogen per gram of oven dry soil (µg nitrogen/g) and results are given in Table 1. At the end of the incubation an average of 98 per cent of the added nitrate was recovered as gas (calculated as nitrogen) plus nitrite- and nitrate-nitrogen.

An analysis of variance of these results indicates that differences in means between treatments, between times, and treatment × time, are all significant at the 0·1 per cent level of probability.

All the freezing treatments increased the denitrifying activity as measured by gas production, so that neither quick freezing using dry ice nor freezing in the refrigerator (and maintenance of low temperatures) preserved the denitrifying activity found at the time of sampling the soil from the field. The lower the temperature maintained for the 28 days after the initial freezing of the soil, the greater the denitrifying activity on subsequent anaerobic incubation. Air drying also increased the denitrifying activity, an observation substantiated by other experiments not reported here.

Evolution of measurable quantities of nitrogenous gases began after the same length of time for all treatments as determined by the manometric technique; the rate of gas evolution also remained constant until the nitrate substrate was exhausted. These observations suggest that any changes in activity or numbers of the denitrifying organisms between treatments are relatively small. The increase in rate of denitrification following soil freezing therefore indicates that the denitrifying organisms are more able to utilize oxidizable substrate, and this could arise from a reduction in numbers of other micro-organisms resulting in an increased nutrient supply for surviving denitrifiers, or from an increase in the availability of the soil organic matter itself. An analogy can be drawn between these results for what is essentially anaerobic respiration in soils and those of Soulides and Allison[2], who found that the effects of freezing and drying of soils were to increase aerobic respiration.

Freezing and drying, therefore, cannot be recommended as a universal means of preserving the denitrifying activity of freshly collected soil. A corollary to this work is that the denitrifying activity of soils in the field, particularly surface soils, could well be expected to change seasonally due to natural freezing and drying. This latter aspect is at present being investigated.

VETERINARY SCIENCE

A Reciprocal Relationship between the Urinary Excretion of Magnesium and Phosphorus in Wether Lambs

In a series of investigations[1] into the cause and prevention of ovine phosphatic urinary calculi, a reciprocal relationship between the urinary excretion of phosphorus and magnesium was observed in wether lambs. Also, lambs which developed visible uroliths in the bladder or kidney excreted more phosphorus and less magnesium than did the non-affected animals.

This pattern was found to hold regardless of the dietary treatment. While the magnitude of excretion changed from year to year and study to study, the decrease in urinary magnesium and the increase in urinary phosphorus in affected wethers were observed in all instances. Table 1 presents the average excretion results from our most recent test. The coefficient of correlation between the excretions of phosphorus and of magnesium was found to be negative and highly significant.

Table 1. Excretion of Magnesium and Phosphorus in 24 h Urine Samples

	No. of samples	Magnesium (mg/100 ml. urine)	Phosphorus (mg/100 ml. urine)
Diet *A*. Average daily intake: 13·8 g Ca, 3·8 g P, 2·9 g Mg (No calculi)			
First 28 days	7	84	2
Second 28 days	7	85	8
Third 28 days	4	64	8
Fourth 28 days	7	69	2
Diet *B*. Average daily intake. 6·7 g Ca, 8·6 g P, 4·9 g Mg (88 per cent calculi)			
First 28 days	6	133	5
Second 28 days	6	99	16
Third 28 days	5	124	16
Fourth 28 days	7	53	34
Diet *C*. Average daily intake. 6·0 g Ca, 5·0 g P, 4 4 g Mg (80 per cent calculi)			
First 28 days	6	31	29
Second 28 days	6	8	66
Third 28 days	3	7	67
Fourth 28 days	8	16	50

$\rho = -0{\cdot}798$, $P < 0{\cdot}01$ (Groups *A*, *B* and *C*). $\rho = -0{\cdot}919$, $P < 0{\cdot}01$ (Groups *B* and *C*). $\rho = -0{\cdot}962$, $P < 0{\cdot}01$ (Groups *A* and *C*).

A comparison of the excretory-levels in animals which developed calculi with those lambs not affected revealed a higher urinary phosphorus and a lower urinary magnesium excretion by affected lambs during the course of the 112–140 day feeding periods on a sorghum grain, cottonseed hull and meal, and molasses based ration. These averages of excretory levels, which were obtained from selected animals in each treatment group, could be used to forecast those treatments which would be calculogenic prior to the development of any serious number of clinical cases of urinary calculi.

The reciprocal relationship between phosphate and magnesium excretions by the kidney may mean that urinary calculi represent one end of a spectrum of metabolic interactions of minerals bounded at the other end by hypomagnesæmic tetany – grass tetany and related maladies.

The accumulation of magnesium in the blood sera of lambs affected with urinary calculi has been previously reported[2].

PSYCHOLOGY

Relations between Excitatory and Inhibitory Retinal Responses as determined by a Revised Apparatus for the Study of Induced Negative After-Images

Induced negative after-images are of interest in that they reflect relations between inhibitory and excitatory retinal function. In 1897, Bidwell[1] reported that when a coloured, a white, and a black stimulus are repeatedly presented in that order for certain durations and at certain intensities, only the complement of the coloured stimulus is perceived. This effect facilitates certain after-image investigations as decisions as to reversal of colour are made more readily than are estimates of after-image duration or intensity. Suitable durations for coloured, white, and 'black' stimuli are 0·017, 0·10, 0·083 sec respectively; the matter of suitable brightness is the principal concern of this communication.

In 1950, Lehmann[2] reported that if the coloured stimulus is maintained at a lower level of illumination than is the white stimulus as the illumination of the system is varied there is a threshold below which only the colour of the stimulus and above which only its complement is perceived. Kaplan[3] also devised an apparatus in which the coloured stimulus was maintained at a fixed fraction of that of the white stimulus as both were varied. The equipment of both these investigators could determine only one point on a curve of brightness of coloured versus brightness of white stimulus at which reversal of perception took place; it seemed indicated to more completely determine this curve, and modifications of the apparatus of Lehmann and Kaplan made this possible. The observer views a coloured stimulus through an eyepiece with an aperture smaller than the meiotic human pupil so that changes in the diameter of the observer's pupil will not affect retinal illumination. An episcoster disk slotted for 30° to expose the coloured stimulus, white for 180° (this constitutes the white stimulus), and black for 150° (this constitutes relative absence of stimulus), rotates between the eyepiece and the coloured stimulus. The disk rotates at a speed of 5 r.p.s., which presents coloured, white, and 'black' stimuli for 0·017, 0·10, 0·083 sec, respectively. A diffuse light source illuminates the episcoster from considerably above and slightly in front (observer's side is front); a diaphragm between this source and the disk alters the illumination of the disk and, thus, the brightness of the white stimulus. The coloured stimulus, a section of opal glass trans-illuminated from the rear, is situated considerably behind the episcoster. Filters between its trans-illuminant and the opal glass determine the chromacity and intensity of the coloured stimulus. A horizontal partition extending from just above the episcoster does not shade the episcoster but effectively shades the coloured stimulus from the light incident on the episcoster. The brightness of the stimuli were calibrated by photo cells; differences in brightness are reliable and consistent. The system, as seen through an artificial pupil in the eyepiece, consists of a coloured spot intercepting 1½° of a 10° white field.

Fig. 1 demonstrates the curves reported by two observers experienced in the use of the apparatus when the brightness of a red stimulus (the light passing through 620 m.μ. interference filter) was set at the values indicated, and the brightness of a white stimulus (colour temp. 2,860° K) increased until green rather than red was perceived. Brightness is expressed in terms of millilamberts rather than in terms of trolands as the latter would depend on details of construction of the apparatus, particularly that of the eyepiece. It is expected that if another apparatus were constructed curves of similar slope and shape but differing in absolute values would be determined. Curves of like configuration were reported by 8 of 10 observers; the absolute values of points on the curve vary among observers and for the same observer over time. Immediately consecutive determinations of points on the curve or of the curve by the same observer are consistent. At and below the lower end of the curve decisions are complicated by transitional colours and whites; at and above the upper end of the curve, colour and complement are alternately perceived. The limits at which reversal is perceived vary among observers. Similar results are obtained using stimuli of other colours but colour reversal is most clear with long wave-length stimuli.

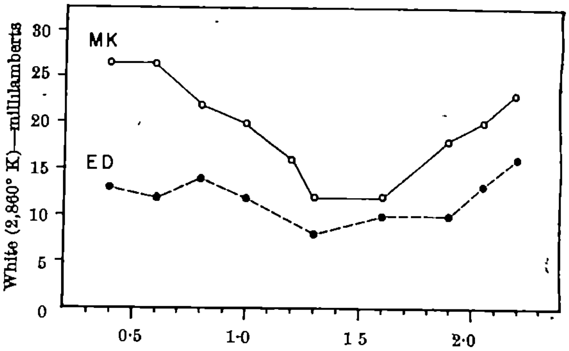

Fig. 1. Brightness of red and white stimuli at which, when the brightness of the red stimulus is held constant and that of the white stimulus increased, green rather than red is first perceived. (Red, white and 'black' stimuli presented repeatedly in that order for 0 017, 0·10, 0·083 sec respectively)

When the brightness of white is decreased until the colour of the stimulus rather than its complement is reported reversal occurs at lower brightness-levels of white. Colour reversal can be observed when the brightness of the white stimulus is held constant and the brightness of the coloured stimulus altered, but the transition is slow and endpoints are uncertain. (Reversal occurs at virtually the same brightness of the white stimulus at a wide range of brightness values of the coloured stimulus.)

That an induced negative after-image of a stimulus can suppress perception of the stimulus demonstrates that under certain conditions a stimulus can have greater inhibitory than excitatory effect. Reversal can be observed, in the conditions given, at a limited range of brightness of the white stimulus. This, as well as the fact that the reversal is perceived at different brightness levels of white when white is increased than when white is decreased, suggests that light adaptation, as determined by the brightness of the white light, plays a part in the phenomenon. The existence of ascending and descending limbs indicates that in this range of illumination, definitely photopic, there is not a constant relation between inhibitory and excitatory response as the brightness of the stimulus varies. This effect, besides being of theoretical interest, may be of use as a parameter of the relation between inhibitory and excitatory retinal function in a variety of physiological and pharmacological circumstances.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Wednesday, January 2

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 10 a.m.—*Symposium on "Masers and Lasers"*.

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. A. J. Sutcliffe: "Caves—their History and Exploration" (Dr. Mann Juvenile Lecture).

Institute of Petroleum (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. I. R. H. Crail, Mr. J. S. Elliott, Mr. D. C. Pearman and Mr. G. H. J. Simmons: "The Effect of Polymeric Dispersants on Engine Sludge".

Thursday, January 3

Institute of Refrigeration (at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, Southwark Bridge Road, *London*, S.E.1), at 5.30 p.m.—Dr. F. L. Levy: "A Review of Methods of Refrigerating Road Vehicles".

Institute of Metals (at 17 Belgrave Square, London, S.W.1), at 7 p.m.—Dr. J. S. Clarke. "Why Cannot Metallurgists Provide the Materials Required by Engineers?".

Friday, January 4

British Mycological Society (at the School of Pharmacy, Brunswick Square, London, W.C.1), at 11 a.m.—General Papers.

Plastics Institute (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 2.30 p.m.—Mr. J. J. P. Staudinger: "Plastics in the World Today" (Young People's Lecture).

Society of Chemical Industry, Fine Chemicals Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. M. G. J. Beets. "Odour and Molecular Constitution".

Saturday, January 5

London County Council (at the Horniman Museum, London Road, Forest Hill, *London*, S.E.23), at 3.30 p.m.—Mr. Geoffrey Kinns: "Photographing Wild Life".*

Monday, January 7

British Institution of Radio Engineers, Research Committee (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 2 p.m.—Symposium on "Radio and Electronics Research in Great Britain".

University College, London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5 p.m.—Prof. Harland G. Wood (U.S.A.): "The Problems of Determining Pathways of Carbohydrate Metabolism Using Labelled Glucose". *(Further lecture on January 10.)**

Institution of Mechanical Engineers, Steam Plant Group (at Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Testing of Modern Large Steam Generating Plant".

Royal Institute of Chemistry, London Section (joint meeting with the London Section of the Society of Chemical Industry, at the Society of Chemical Industry, 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. Alexander King: "Scientific Research in Europe in Relation to Economic Development".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned·

Head (with a higher degree, and substantial teaching and industrial experience) of the Department of Electrical Engineering (Grade IV), Enfield College of Technology—The Chief Education Officer (F.3), 10 Great George Street, Westminster, London, S.W.1 (January 4).

Teaching Fellow (with an honours degree or equivalent qualifications) in the School of Chemistry, University of New South Wales—The Agent-General for New South Wales, 56 Strand, London, W.C.2; and the Appointments Section, The University of New South Wales, P.O. Box 1, Kensington, New South Wales, Australia (January 11).

Biologist (pre- or post-doctoral appointment) to assist in Chromosomal Research *with a leaning to leukaemia—The Professor of* Haematology, King's College Hospital Medical School, Denmark Hill, London, S.E.5 (January 12).

Lecturer (with interests in (a) the instrumental methods for control of semi-technical or pilot-plant processes and equipment and/or (b) *modern methods of analytical chemistry, particularly instrumental* methods) in Chemistry—The Registrar, The Manchester College of Science and Technology, Manchester, 1 (January 12).

Chair of Clinical Chemistry—The Secretary, The University, Edinburgh (January 14).

Research Assistant (*with qualifications in mathematics, physics* or chemistry) for Electronic Computing in the Department of Inorganic and Structural Chemistry and in the Electronic Computing Laboratory, to help in the development of programmes for crystal structure analysis on the KDF9 computer—Dr. M. R. Truter, School of Chemistry, The University, Leeds, 2 (January 15).

Senior Lecturer or Lecturer in Oceanography (Biological or Physical) at the University of Natal, South Africa—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, January 15).

Curator or Assistant Curator (honours graduate) of Fishes at the Australian Museum, Sydney, New South Wales—The Agent General for New South Wales, 56 Strand, London, W.C.2 (January 18).

Assistant Experimental Officer (preferably with a Higher National Certificate or a degree in a biological subject) for research in the Nematology Section—The Secretary, Glasshouse Crops Research Institute, Worthing Road, Rustington, Littlehampton, Sussex (January 19).

Physical or Organic Chemist (*with a university degree or a* diploma or equivalent qualifications with physical chemistry or organic chemistry as a major subject, together with some years of appropriate chemical experience, preferably involving instrument methods) in the Division of Coal Research, Commonwealth Scientific and Industrial Research Organization, North Ryde, *New South Wales, Australia, to take part* in investigations into the development of physical methods of organic analysis, particularly in the field of gas chromatography—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 480/422 (January 19).

Scientific Officer or Senior Scientific Officer (preferably with an honours degree in chemistry or biochemistry, or a biologist with sound experience of pesticides research) for research in the Crop Husbandry Department—The Secretary Glasshouse Crops Research Institute, Worthing Road, Rustington, Littlehampton, Sussex (January 26).

Lecturer in Pharmaceutical Chemistry (Physical Chemistry) at *the University of Sydney, Australia—The Secretary,* Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 29).

Chair of Philosophy in the University of the Witwatersrand, *Johannesburg, South Africa—The Secretary, Association of Universities* of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, January 31).

Computation Director (with experience of electronic computation) to organize and run a small computation laboratory, operating in conjunction with a quantum theory group—Dr. R. McWeeny, The University, Keele, Staffs (January 31).

Lecturer in Chemistry at Fourah Bay College (The University College of Sierra Leone)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (January 31).

Research Assistant (with an honours degree in chemistry) in the Department of Oceanography *to assist in research in chemical* oceanography—The Registrar, The University, Liverpool, quoting Ref. No. CV/225/N (January 31).

British Nylon Spinners Postdoctoral Fellowship in Physics—The Registrar, The University, Bristol 8 (February 1).

Lecturer in Biochemistry in the Department of Physiological Chemistry—The Registrar (Room 22, O.R.B.), The University, Reading (February 1).

Chair of Agricultural Economics at Monash University, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1; or The Registrar, Monash University, P.O. Box 92, Clayton, Victoria, Australia (Australia and London, February 4).

Official Fellow and Tutor in Philosophy—The President, Corpus Christi College, Oxford (February 9).

Veterinary Parasitologist (with a degree in veterinary science or equivalent qualifications, and some years of appropriate post-*graduate research training)* in the McMaster Animal Health Laboratory, Commonwealth Scientific and Industrial Research Organization, Sydney, to participate in specific aspects of the programme of research concerned with the epidemiology and control of helminth infections of sheep with particular reference to infections with *Ostertagia* sp. in the first instance—*Chief Scientific Liaison Officer,* Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 202/200 (February 9).

Chair of Chemistry; Chair of Zoology; and Chair of Botany at Fourah Bay College (The University College of Sierra Leone)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (February 15).

Official Fellow and Tutor in Pure Mathematics—The Master, St. Catherine's College, Oxford (February 15).

Official Fellow in Mathematics (pure or applied)—The Principal, Hertford College, Oxford (February 19).

Assistant Physicist (with a good honours degree in physics) in the Regional Medical Physics Department of the Sheffield Regional Hospital Board—The Secretary, Sheffield Regional Hospital Board, "Broom Cross", Tree Root Walk, Sheffield 10.

Biochemist (Basic grade)—The Superintendent, The Children's Hospital, Western Bank, Sheffield 10.

Experimental Officer (male, graduate in horticulture, botany *or forestry, keenly interested in the scientific aspects of practical* fruit culture and in people, and preferably some knowledge of languages) in the Scientific Liaison Section—The Secretary, East Malling Research Station, Maidstone, Kent.

Lecturer in the Department of Medical Microbiology at Makerere University College, East Africa—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

Lecturer (with an interest in physical metallurgy) in Chemical Engineering at the University of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

Research Assistant (with an honours degree in zoology), for work on the reticuloendothelial system of lower vertebrates—Prof. G. E. H. Foxon, Biology Department, Guy's Hospital Medical School, London Bridge, S.E.1.

(not included in the monthly Books Supplement)

Great Britain and Ireland

Philosophical Transactions of the Royal Society of London. Series A: Mathematical and Physical Sciences. No. 1050, Vol. 255, (25 October, 1962): Studies of the Jahn-Teller Effect. 4. The Vibrational Spectra of Spin-Degenerate Molecules. By M. S. Child. Pp. 31–53. 7*s.* 6*d.* No. 1051, Vol. 255 (25 October, 1962): The Band Structure and Fermi Surface of Magnesium. By L. M. Falicov. Pp. 55–83. 9*s.* (London: The Royal Society, 1962). [8010

The Future of Optical Astronomy. By Prof. D. E. Blackwell. (An Inaugural Lecture delivered before the University of Oxford, 12 June 1962.) Pp. 19. (Oxford: Clarendon Press; London: Oxford University Press, 1962.) 3*s.* 6*d.* net. [111

Department of Scientific and Industrial Research. Summary of Progress of the Geological Survey of Great Britain and the Museum of Practical Geology for the year 1961, with Report of the Geological Survey Board. Pp. iii+83. (London H.M. Stationery Office, 1962.) 5*s.* 6*d.* net. [111

Department of Technical Co-operation. Technical Co-operation under the Colombo Plan: Report for 1961–62 of the Council for Technical Co-operation in South and South-East Asia. Pp. 92. (London: H.M. Stationery Office, 1962). 5*s.* net. [111

The Tropical World. By Prof. D. L Linton. (An Inaugural Lecture delivered in the University of Birmingham on 9th May 1961). Pp. 18 (Birmingham: The University, 1962.) 2*s.* 6*d.* [711

The Chest and Heart Association. Annual Report 1961–1962. Pp. 8 (London: The Chest and Heart Association, 1962.) [711

Ciba (A.R.L.), Ltd. Technical Notes, No 238 (October, 1962): Mouldings from Wood Chips and Aerolite. Pp. 11. (Duxford: Ciba (A.R.L.), Ltd., 1962.) [711

British Broadcasting Corporation. BBC Engineering Monograph No. 44: A Band V Signal-Frequency Unit and a Correlation Detector for a VHF/UHF Field-Strength Recording Receiver. Part 1: A Band V Signal-Frequency Unit By Dr. C J. Phillips and P. T. W Vance. Part 2: A Correlation Detector. By R. V. Harvey Pp 24. (London: British Broadcasting Corporation, 1962) 5*s.* [711

International Association for the Exchange of Students for Technical Experience. Report of IAESTE in the United Kingdom for year ending September 1962. Pp. 18. (London: International Association for the Exchange of Students for Technical Experience, 1962). [711

British Education. By H. C. Dent New Edition. Pp. v+70+17 plates. (London: Longmans, Green and Co., Ltd., 1962.) 2*s.* 6*d.* [711

Association of Universities of the British Commonwealth. United Kingdom Postgraduate Awards, 1962–64: Fellowships, Scholarships, Grants, etc. tenable at Universities in the United Kingdom; Short List of Awards tenable outside the United Kingdom. Pp. 149. (London: Association of Universities of the British Commonwealth, 1962.) 5*s.* [711

Cement and Concrete Association. An ABC of Prestressed Concrete. By M. R. Hollington. Pp 56. (London: Cement and Concrete Association, 1962.) [711

Scottish Marine Biological Association. Annual Report, 1961–62. Pp 37. (Millport, Isle of Cumbrae: Scottish Marine Biological Association, 1962.) 4*s.* [711

National Union of Teachers. Revalue the Teacher! Pp. 16. (London: National Union of Teachers, 1962.) [911

Privy Council. Medical Research Council Special Report Series No. 302. Tables of Representative Values of Foods Commonly Used in Tropical Countries. By B. S. Platt (Revised edition of Special Report, No. 253.) Pp v+46. (London: H.M. Stationery Office, 1962.) 7*s.* net. [911

The Royal Society. British National Committee on Space Research. United Kingdom Report for 1961 to the the I.C S.U. Committee on Space Research, submitted to the Fifth Meeting of Cospar, Washington, 30 April—9 May, 1962. Pp. 23. (London The Royal Society, 1962.) [911

Minerva: a Review of Science, Learning and Policy, Vol. 1, No. 1, (Autumn 1962). Edited by Prof. Edward Shils. Pp. 1–144. Published under the auspices of the Committee on Science and Freedom Subscription rate: 20*s.* or 5 dollars a year. Single issues 5*s.* (London: C.F.S. Publications, Ltd., 1962.) [911

The Health of the School Child: Report of the Chief Medical Officer of the Ministry of Education for the years 1960 and 1961. Pp. xi+248+14 photographs. (London: H.M. Stationery Office, 1962.) 15*s.* net. [911

Meteorological Office. Scientific Paper No. 16: An Experiment in Operational Numerical Weather Prediction. By E. Knighting, G A. Corby and P. R. Rowntree. Pp. iii+28. (London: H.M. Stationery Office, 1962.) 3*s.* net. [911

Building Research Station Digests, (New Series), No. 28. Factory Building Studies. Pp. 6. (London: H.M. Stationery Office, 1962) 4*d.* [911

The Chester Beatty Research Institute Serial Abridged Life Tables. England and Wales, 1841–1960. Part 1: Tables, Preface and Notes. Compiled by R. A. M. Case, Christine Coghill, Joyce L. Harley and Joan T. Pearson. Pp. xxvi+87. (London: The Chester Beatty Research Institute, Institute of Cancer Research, Royal Cancer Hospital, 1962) [911

University Grants Committee. Returns from Universities and University Colleges in receipt of Treasury Grant, Academic Year 1960–1961. (Cmnd. 1855). Pp xxiv+48. (London. H.M. Stationery Office, 1962.) 5*s.* 6*d.* net. [1411

On Having a Mind. By Prof. William Kneale (The Sixteenth Arthur Stanley Eddington Memorial Lecture, 9 November 1962.) Pp. 56. (Cambridge: At the University Press, 1962.) 4*s.* 6*d.* net.; 95 cents [1411

Tin Research Institute. Publication No. 384: Hot-Dip Coating with Tin-Lead Alloys. By C. J. Thwaites. (Reprinted from *Metal Industry*, 24th August 1962, p. 142). Pp. 11. (Greenford, Middx.: Tin Research Institute, 1962.) [1411

General Register Office. The Registrar General's Statistical Review of England and Wales for the year 1960. Part 3: Commentary. Pp. xiv+281. (London: H.M. Stationery Office, 1962.) 21*s.* net. [1411

Other Countries

National Institute of Genetics, Japan. Annual Report, No. 12, 1961. Pp. vi+128. (Misima, Sizuoka-ken: The National Institute of Genetics, 1962.) [1

Institut Royal des Sciences Naturelles de Belgique. Mémoires, Deuxième Série. Fasc. 68: Les Archaeogastropoda Fossiles du Cénozoique Étranger—Des Collections de l'Institut Royal des Sciences Naturelles de Belgique Par Maxime Glibert. Pp. 131. Fasc. 6 Les Mesogastropoda Fossiles du Cénozoique Étranger—Des Collectio de l'Institut Royal des Sciences Naturelles de Belgique. Premiè Partie Cyclophoridae à Stiliferidae (Inclus.). Par Maxime Glibe Pp. 305. (Bruxelles: Institut Royal des Sciences Naturelles Belgique, 1962.) [1

Year Book of the National Institute of Sciences of India, 196 Pp. viii+247. (New Delhi: National Institute of Sciences of Ind 1962.) [7

British Guiana: Geological Survey. Report on the Geologic Survey Department for the year 1960. Pp. 72. 1 dollar. Bulle No. 33: The Geology of the South Savannas Degree Square. By C. Barron. Pp. 20+3 plates. 4.80 dollars. Geological Maps. Quar Degree Sheet 0359SW: Kanuku SW. Quarter Degree Sheet 0458S Kurupukari SW. Quarter Degree Sheet 0658NW: Georgetown N Quarter Degree Sheet 0659 SE: Purum SE. Quarter Degree Sh 0659NW: Ourumi NW. 1 dollar each. (Georgetown, British Geological Survey, 1961 and 1962.)

The International Association for the Exchange of Students Technical Experience. Fifteenth Annual Report, 1962. Pp. 88. (B Godesberg: Dr. Klaus Wyneken, General Secretary, IAESTE, 1962.)

International Council of Museums. Science Museums in Develo Countries. By Frank Greenaway. With additional chapters by Torst Althin, W. T. O'dea and W. Stephen Thomas. Pp. vi+66. (Par International Council of Museums, 6 rue Franklin, 1962.) 4 NF, 7 80 cents. [7

Indian Forest Bulletin, (New Series). No. 236: (Wood Seasoning) Experiments on High Temperature Drying of some Indian Timbe Part 2. By S. N. Sharma, B. I. Bali and M A. Rehman. Pp. iii+ (Delhi Manager of Publications, 1962.) Rs. 1·80nP., 4*s.* 8*d.*; cents. [7

World Meteorological Organization. Microcards of IGY Meteo logical Data—Classification for Information Storage and Retriev By Gertrude London Pp. x+78. (WMO–No. 123, IGY.3). (Genev World Meteorological Organization, 1962). 7 Swiss francs. [7

The Coconut Industry Board, Jamaica. Second Report of Research Department, June 1961—June 1962. Pp. 40. (Kingst W.I.: Coconut Industry Board, 1962.) [7

II Congreso Venezolano de Salud Publica, 25 de Febrero al 3 Marzo de 1961. (*Revista Venezolana de Sanidad y Asistencia Soci* (Ediciones Especiales), Supplemento al No. 1, Marzo, 1961 y No. Junio, 1961). No. 1: Pp. 528. No. 2 Pp. 98. (Caracas, Venezuel Ministerio de Sanidad y Asistencia Social, 1961.) [7

East African Common Services Organization. The East African Council for Medical Research—Annual Report, 1961/62. Pp. iii+1 (Nairobi: East African Common Services Organization, 1962.) 2*s.* [7

British Territories in Borneo. Annual Report of the Geologic Survey Department for 1961. Pp. viii+138+26 plates. (Kuchin Geological Survey Department, 1962.) [71

New Zealand Marine Department. Fisheries Technical Report No. 6: Occurrence and Distribution of the Dredge Oyster (*Ostr sinuata*) in Tasman and Golden Bays. By B. R. Tunbridge. Pp. i+4 No. 7: Yellow-Eyed Mullet *Aldrichetta forsteri* (Cuvier and Valen ennes) in Lake Ellesmere. By T. B. S. Gorman. Pp. ii+20. (Wellingto New Zealand: Government Printer, 1962.) [7

General Dynamics/Astronautics, San Diego. Tables for Hyp osculatory Interpolation. By Herbert E. Salzer. Pp. ii+51. (Diego, Calif.: General Dynamics/Astronautics, 1962.) [7

Conseil Permanent International pour l'Exploration de la M Charlottenlund Slot, Danemark. Bulletin Hydrographique pour l'Ann 1956. Publié par le Bureau du Conseil, Service Hydrographique. P xi+217. (Copenhague: Andr. Fred. Høst et Fils, 1962.) Kr. 70. [7

Académie Royale de Belgique. Classe des Sciences. Mémoires, Ton 33, Fascicule 4. Observations Complémentaires au sujet de l'Influenc du Granite sur les Déformations Mineures des Roches dans le Mass Armoricain. Par Prof P. Fourmarier, Prof. Cl. Pareyn et Fr. Dor Pp. 66. (Bruxelles Académie Royale de Belgique, 1962.) 80 francs. [91

University of California Publications in Geological Sciences. Vol. 4 No. 3 Late Cenozoic Geology of McGee Mountain, Mono County California. By William C. Putnam. Pp. 181–218 (6 plates). (Berkele and Los Angeles: University of California Press; London: Cambridg University Press, 1962.) 1.50 dollars.* [9

Chicago Natural History Museum. Fieldiana: Geology. Vo. 10, N 37: The Walters Meteorite. By Sharat Kumar Roy, Jewell J. Glas and Edward P. Henderson. Pp. 539–550. 35 cents. Fieldiana: Zoology Vol. 44, No. 12: New Birds from Barotseland. By Melvin A. Traylo Pp. 113–116. 10 cents. Vol. 44, No. 13: A New Gekkonid Lizard of th Genus *Cyrtodactylus* from the Philippine Islands. By Wayne King Pp. 117–120. 10 cents. Vol. 44, No. 14: A New Race of *Penelop montagnii* from Southeastern Peru. By Emmet R. Blake. Pp. 121–12 10 cents. (Chicago: Chicago Natural History Museum, 1962.) [91

Population Reference Bureau, Inc. Annual Report, 1961. Pp. 16 (Washington, D.C.: Population Reference Bureau, Inc., 1962.) [91
